Blogging: A multimodal perspective

Suriati Abas
Beacon Primary School

This paper documents how children embed multimodality in their journal entries using blogs. Multimodality is the combination of semiotic modes that may include spoken language(s), written language(s), static or moving images and music. Each of them generally offers opportunities for the construction of meaning. In this research, a case study approach was employed to gain an in-depth understanding of multimodality and meaning-making. The data is collected using classroom observations, textual analysis of similar journal topics posted by the participants, and informal interviews, or, online responses to the comments posted by the teacher, to the pupils in their entries which take the form of blog posts. Findings of this investigation suggest a need to redesign learning to allow everyone to cope with multimodality as a new form of literacy.

Keywords: multimodality, blogging, journal entries, semiotic modes, engagement

Introduction

The ubiquity of digital technology has transformed the way people work, learn, play and even communicate. While previously a text comprises mostly printed words, the definition has since then been extended to include several dimensions which moves away from the notion that language is the dominant mode in meaning-making work. Hence, in view of this, the study attempts to account for the burgeoning variety of text forms associated with information and multimedia technologies by investigating multimodality in the journal entries of children.

Research Focus

The aim of this paper is to investigate how multimodality is represented in the journal entries of children. However, for this research, only the conjunction of images and texts were analysed as these are the representational modes that are often used by children (Sutherland-Smith, 2002).

Bearing in mind that children receive information multimodally (Bearne, 2003), the paper sought to argue for a shift towards the new literacy pedagogy by understanding the following questions:

- How do children make use of multimodality to add an additional layer of meanings in their journal entries?
- What do the images and text mean to them?

Theoretical Framework

For the analysis, two conceptual frameworks were used. The first drew on distinctions offered by the American philosopher, Charles Sanders Peirce's model, between icons, indexes (indices) and symbols. To illustrate these concepts briefly, consider any pictorial image of a rabbit. According to Peirce (1955), this picture would be an icon if it mimetically represents a rabbit. However, if the image refers to the idea of the white rabbit, as purity, then it would be regarded as an index. On the other hand, if the image of the rabbit represents a company's trademark, then it would be considered as a symbol. In all, the three categories posited by Peirce are not separate or distinct because they "represent the world simultaneously in various degrees" (Danesi, 1994). Hence, knowledge of this classification provides a language to talk about the various types of visual representation.

Additionally, since all images are polysemic, open to endless interpretations, thus, a linguistic message has to be associated with the image. Hence, for a framework to describe children's interpretation of images and text, the distinctions presented by Roland Barthes, a French philosopher, linguist and educator were used. According to Barthes (1977), the relationships between text and image could be bifurcated as anchorage and relay. In anchorage, the text elaborates the image by directing the reader through the signifieds of the image. Nonetheless, it is possible for the image to elaborate the text such that the image forms an illustration of it. Meanwhile, in relay, the text and image are in a complementary relationship and they are "fragments of a more general syntagm" (Kress & van Leeuwen, 1996) such as in comic strips and films. Of the two, "anchorage is most frequent function of the linguistic message" (Barthes, 1977). Nevertheless, in meaning-making, any permutations of image-text relation could exist depending on the semiotic choices that best fit the message.

Literature review

Kress (2000) found that students used different kinds of representational resources, to write their Science report. When they were instructed to explain a plant cell that they had observed, they communicated their ideas visually and linguistically through the 'orchestration of semiotic modes' (Kress & van Leeuwen, 2001) with each mode contributing to the overall meaning. In another study, Hull and Nelson (2005) argued that the expressive power of multimodality resides in the semiotic relationships between and among different modes. While different semiotic modes attempt to encode similar content, they might not convey similar meanings for, each mode perform "different communicative work" (Jewitt, 2009) in a multimodal ensemble. In view of the subjectivity involved in multimodality, Bearne (2009) created a framework to analyse multimodal texts using analytic categories such as image, language, sound, gaze and movement. From the three examples that she studied, she found that the seven-year-old children used a combination of modes to express themselves. While the analysis were done separately for image, sound, gaze and movement, it was acknowledged that different modes work together to make meanings (Kress, 2003) as children think 'multidimensionally' (Bearne, 2005). Clearly, had language alone been used to gauge the rhetorical success of the text in this study, much learning would have been lost in making meanings.

Methodology

Research design and instrument

For this research, a case study approach was employed. Before embarking on the study, permission was sought from the school principal, and the intent of the study was explained. To comply with ethical principles (Cohen & Manion, 1994), the participants were informed that their journal entries would be collated for research purposes. They were assured that their confidentiality would be protected and that pseudonyms would be used in reporting the research data, to remain anonymous. The data are collected using field notes based on her classroom observations, textual analysis of seven similar journal topics posted by the participants, informal interviews.

Participants

The participants were three ten-year-old children in the same class. These pupils were chosen because they are regular contributors to the journal entries. Besides, each of them represents the low, middle and high proficiency group of pupils from a cohort of 240 ten-year-old children in a school.

Research Procedure

In the first few sessions, the pupils were given topics which are close to their experiences so that they would not feel daunted to write. After all the journal entries for the day have been posted onto the blogs, the teacher highlighted three interesting entries, asking each of the selected children to justify to the other pupils why he or she has included a certain image in the post. She then intervened in their meaning-making works to create greater semiotic awareness which are central to multimodal learning and development (Jewitt, 2008b). Before the children posted their entries, she showed them examples of how particular meanings could be constructed through images and text to communicate a specific idea, for three consecutive sessions. Subsequent journalling sessions ensued with the teacher initiating the topic, along with several guiding questions placed on the whiteboard, to assist the less proficient pupils in expressing their thoughts in the blogs.

Discussion of findings

From the selected journal entries, the three children combine modes to communicate meanings with rhetorical force. They express themselves visually using Peircian's 'icon', 'index', 'symbol' or by blending any of them together in the linguistic mode. However, analysis of the data shows that these children make use of multimodality differently in their journal entries, albeit given similar topic. It could be due to their awareness of the 'potential affordances' (Kress, 2003) of what a certain mode can or cannot do.

The children employed different semiotic choices, with the visual mode, being the dominant ones, to create particular meanings as in Table 1.

Primary data (Selected journal topics)	Codes (Inference/ Abstraction)				Discovery memos
	Modes/Pupils	**Eileen**	**Ben**	**Danny**	**Eileen, Ben & Danny**
1. What colour is Thursday?	Visual representation	Index	index	symbol	1) The three children use different modes in similar journal entries to create particular meanings. 2) They employ different visual representation modes but have common understanding of image-text relations as they make meanings. 3) Multimodal meaning-making enables linguistically at-risk children to express themselves well using other modes than written language 4) Children tend to be skeptical of employing visual images as form of language representation.
	Image-text relation	anchorage	anchorage	anchorage	
2. My favourite song	Visual representation	icon [‘offer’ image]	icon [‘demand’ image]	icon [‘demand’ image]	
	Image-text relation	relay	relay	relay

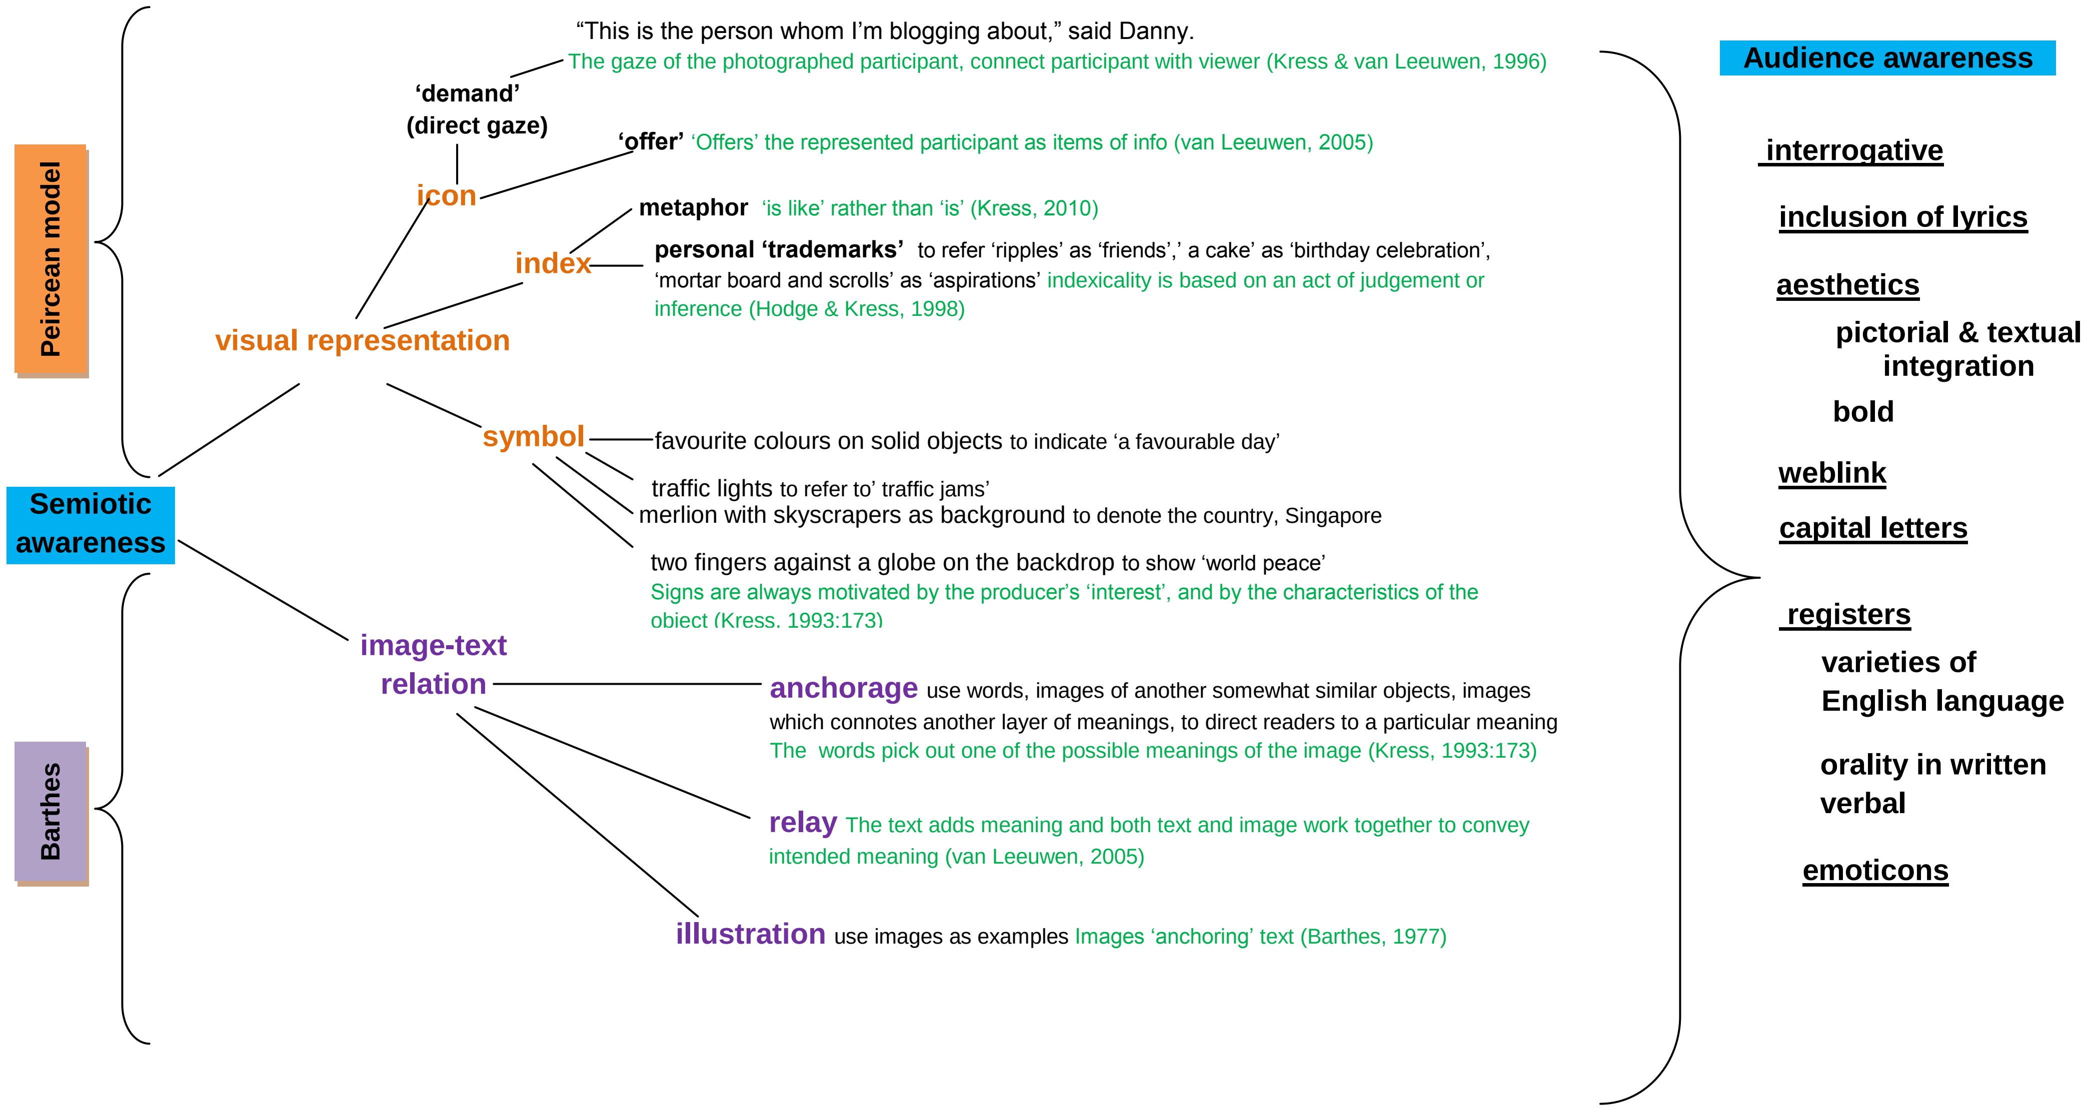
7. A picture story	Visual representation	icon	index	icon, index & symbol	
	Image-text relation	NONE	relay	NONE	

Table 1: Summary of semiotic choices made by Eileen, Ben & Danny

Secondly, although the children made different semiotic choices in their visual representation, they interpret the image-text relations in a similar way. (Refer to Figure 1)

Third, even if the semiotic choices vary according to particular meanings, all three children demonstrated authorial intent in some of their entries. This certainly shows that they have some sense of inter-semiotic awareness. However, the level of explicitness varies perhaps due to their experience in multimodal communication. In the entry, 'Images & text', Eileen employed mostly linguistic structures in standard English language. She used pronomial references, 'I' and 'you', and, added interrogatives to engage the readers. She even inserted emoticons to show them her contentment apart from using words to express her feelings. On the other hand, Ben aims to interact with his audience using a less formal variety of English language, consciously changing to orality in his written language to establish casualness, which is typical of bloggers. The fact that he applies 'bold' typefaces on all his entries suggests that he understood the visual affordances of written language and how it fits the needs of his reader

Figure 1: Tree diagram drawn from analysis of the journal entries of Eileen, Ben & Danny



In sum, analysis of the journal entries suggest that children who have less control over linguistic structures perform well in constructing meanings in other semiotic modes, such as visual images. Hence, limiting assessment to written language may hinder the success of this group of children. To ensure that they are fairly assessed and all children are given the opportunity to acquire various forms of literacies, I would argue for a re-thinking of literacy pedagogy.

Implications for language pedagogy

In rethinking literacy pedagogy, it is necessary to consider how children can be taught to make semiotic choices that best fit their intended message. To begin with, the affordances of different modes and how they could work together or separately, in meaning-making, should be made explicit to them. For example, understanding what a visual image could offer that a text might not be able to do, or, knowing the impact a film might have, on a reader that might not be possible by reading a text. Having said that, teaching children to solely recognise representational demands are insufficient, to help them use 'language' meaningfully. There should be some guidelines to indicate their level of achievement in constructing meanings using various modes (Burke & Hammet, 2009).

While tracking progress in multimodal text is not the norm, it is crucial in order to shift towards new literacies. In the light of this, teachers need to develop their professional capital on multimodality. In essence, they need to work with one another closely to define a set of indicators for several dimensions of texts, which comprise visual, sound, voice, intonation, stance, gesture and movement. According to Vincent (2006), a tool is required to monitor the achievements of students who have adopted these alternative pathways to literacy. Arguably, it could be challenging to create such rubrics which takes into account the multimodal aspects of language because as Kress and van Leeuwen (2001) pointed out, each mode has its own grammar and syntax. Therefore, to develop indicators which succinctly demonstrate a child's multimodal progression, teachers have to understand the grammar behind each semiotic mode thoroughly.

In all instances, teachers need to acknowledge and appropriate for themselves the demands of new literacy practices. They should be prepared to adopt the roles of a resource manager, co-constructor of knowledge and a design consultant (Larson and Marsh, 2005) so that they could effectively facilitate learning in the multimodal, electronic space. On hindsight, if the national curricular and assessment mode continues to demand language as a primary system, then most teachers may not even want to invest time thinking about a 'language' which attends to other semiotic modes, than the written mode (Moriarty, 1994). However, resistance to transform literacy pedagogy would place schools at a disadvantage because "new literacies, whether intentionally or unintentionally impact literacy instruction in classrooms" (Leu, Kinzer, Coiro & Cammack, 2004).

Limitations

The findings may not be able to access designs that children use in a more dynamic kind of representational mode. While there are other modes such as moving images, which might allow them to make meanings, this study is limited to static visual images. Hence, future research might want to look into ways in which children combine modes, forming what Kress (2003) termed as 'transformation' (a reshaping of resources within a mode), 'transduction' (a shift of semiotic materials across modes) and 'synaesthesia' (the qualitatively new forms of meaning which occur through transformation and transduction) to obtain a richer understanding of multimodality and meaning-making works.

Conclusion

Throughout the paper, the multimodal character of literacy among children was discussed. Following the points of discussion, it may be claimed that the images and text worked together for an intended purpose in meaning-making. However, they may or may not be explicitly expressed even though the children have a sense of semiotic awareness. Conclusively, making meanings through multiple modes presents a need to redesign learning to allow everyone to cope with multimodality as a new form of literacy.

Age-related differences in ICT access and confidence among pre-service teachers

Peter R Albion

Glenn Finger
School of Education and Professional Studies
Griffith University

The Australian Government's Digital Education Revolution is directed at school education but, because teacher preparation is a significant factor in its success, there are implications for teacher education in Australian higher education. A national project, *Teaching Teachers for the Future*, has been funded to support change in teacher preparation programs based on the construct of Technological Pedagogical Content Knowledge (TPACK), which describes teachers' complex combination of knowledge of content, pedagogy, and technology. Knowledge of information and communication technology is a necessary, but not sufficient, foundation for TPACK. This paper presents data about ICT access and confidence reported by teacher education students in a regional university. Key findings included that teacher candidates had access to and confidence for using common forms of ICT but more limited access to and confidence for using less common forms, and that there were few significant differences in ICT access and confidence according to age.

Keywords: teacher education, TPACK, ICT integration, digital generation

Background

Australian school education is in the throes of a government-sponsored *revolution*. The change of government in 2007 was followed by a series of initiatives collectively known as the *Digital Education Revolution* (DER) (DEEWR, 2008). This continued, and intensified, the commitment of successive Australian governments to broad goals for information and communication technology (ICT) in education, namely that young people should complete their schooling with relevant knowledge and skills for using ICT, and that ICT should be used to improve student learning across the curriculum (Toomey, 2001). Achievement of these goals depends upon multiple conditions, most importantly students in schools having access to sufficient current ICT for learning about and with ICT, curriculum being adapted to incorporate greater use of ICT, and teachers being adequately prepared to work with ICT in their classrooms.

Early phases of the DER included promises of funding to schools to achieve a computer to student ratio of 1:1 for years 9 to 12 by 2011, and improved broadband Internet connections to schools. Despite some challenges in implementation this aspect of the DER has substantially increased access to ICT in schools. At the same time the first phase of the Australian Curriculum (http://acara.edu.au) is being implemented for English, Mathematics, Science and History with other subjects to follow. ICT competence is included as one of seven general capabilities to be addressed across the National curriculum, indicating some progress on the second of the three conditions mentioned above.

The DER has been guided by a roadmap (AICTEC, 2009) that recognized that "educators require the pedagogical knowledge, confidence, skills, resources and support to creatively and effectively use online tools and systems to engage students" (p. 6). The roadmap noted that there would be need to provide professional learning opportunities for existing teachers and to ensure that graduate teacher standards include the use of ICT in teaching. An *ICT Innovation Fund* was established and applications were invited for funding of projects in the areas of improving capability of pre-service teachers, enhancing capacity of in-service teachers, and driving innovation through leadership (DEEWR, 2010a). A group established through the Australian Council of Deans of Education (ACDE) submitted a successful proposal in the pre-service area which attracted funding of $7.8 million for an unprecedented national project, *Teaching Teachers for the Future* (TTF) (ALTC, 2010). TTF involves all Australian Higher Education Institutions (HEIs) that have a teacher preparation program, together with the Australian Learning and Teaching Council (ALTC), Education Services Australia (ESA), the Australian Institute for Teaching and School Leadership (AITSL), and the Australian Council for Computers in Education (ACCE). As submitted, the project was to be led by ALTC but changes to ALTC in early 2011 resulted in ESA assuming the role of lead partner.

The TTF project has three major components that are intended to delineate standards for ICT capabilities of graduating teachers; develop resources to support teacher preparation to meet these standards; and revitalize teacher preparation programs to prepare teachers for integrating ICT in the new national curriculum. The first component is being led by AITSL and ACCE with input from the other partners and the second is being undertaken by ESA, again with input from other partners as appropriate. The third, and by far the largest, component is directly involving the 37 HEIs offering teacher preparation in a process of reviewing and revitalising the ways in which new teachers are prepared to work with ICT. This work is being supported by direct funding to the HEIs to engage personnel who are highly accomplished in teaching with ICT and the development of a National Support Network (NSN) to facilitate the sharing of relevant practice among HEIs. The NSN is intended to continue to function beyond the life of the TTF project which ends in June 2012.

All three components of the TTF project will affect teacher preparation programs in HEIs. Clarification of how ICT capability is demonstrated in the AITSL standards for graduates will affect curriculum and assessment for teacher preparation programs and the resources being developed by ESA will affect how certain elements of such courses are offered. However, the most direct and immediate effect will be through the third component as courses are progressively examined for their contribution to developing ICT capability and appropriately adjusted. This paper addresses some background to course revision by examining some pre-existing factors that may influence the changes that will be required.

Technological Pedagogical Content Knowledge

The teacher preparation component of TTF has adopted Technological Pedagogical Content Knowledge (TPACK) (Mishra & Koehler, 2006) as its underpinning conceptual framework and will draw upon previous work (Albion, Jamieson-Proctor, & Finger, 2010; Jamieson-Proctor, Finger, & Albion, 2010) in developing its evaluation strategy. Koehler, Mishra and Yahya (2007, p. 741) have argued that:

> intelligent pedagogical uses of technology require the development of a complex, situated form of knowledge [called] Technological Pedagogical Content Knowledge (TPCK). At the heart of

> TPCK is the dynamic, transactional relationship between content, pedagogy and technology. Good teaching with technology requires understanding the mutually reinforcing relationships between all three elements taken together to develop appropriate, context specific strategies and representations.

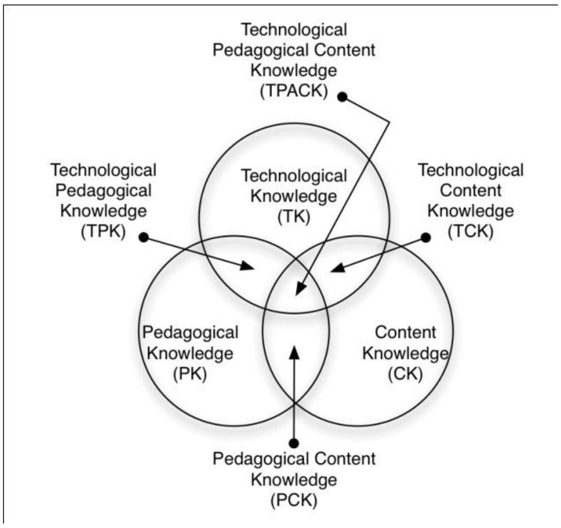

Figure 1: TPACK Conceptualization (After Mishra & Koehler, 2006)

According to Mishra and Koehler (2006) TPACK encapsulates knowledge of content, pedagogy, and technology, as well as an understanding of the complex interaction between these three main knowledge sets. They argue that teachers who have this level of understanding are characterized by the creative, flexible, and adaptive ways in which they navigate the affordances, constraints, and interactions within and among the TPACK framework elements.

More recently, Graham (2011) has examined the theoretical underpinnings of TPACK and has identified areas that require further development to ensure adequately shared understanding among researchers and practitioners. One issue that he identified was whether the areas of intersection should be understood as *integrative*, representing a combination of the intersecting kinds of knowledge, or *transformative*, representing a new synthesised form of knowledge that is more than the sum of its parts. Graham notes that although the descriptions offered by Mishra and Koehler (2006) imply a transformative understanding the conventional diagram is generally understood as integrative.

A further issue identified by Graham (2011) is with the understanding of *technology* in the TPACK model. Mishra and Koehler (2006) included older technologies such as the pencil and chalkboard, implying that technological knowledge and TPACK would be required for every teaching situation. Graham refers to work from Cox (2008) who distinguished between *transparent* and *emerging* technologies, with the former being familiar technologies in ubiquitous use (pencil, chalkboard, etc.) and the latter referring to being the newer, less familiar and mostly digital technologies being introduced. This is a useful distinction in relation to how knowledge of transparent technologies may be subsumed into pedagogical and content knowledge.

The TPACK framework almost suggests a new form of literacy for teachers, a literacy that emphasizes an active role for the teacher as a producer, a designer, which is very different from the traditional static idea of teachers as consumers or users of technology. Further, the TPACK model implies a ‘system’ which is in a constant state of flux and this system requires teachers to make thoughtful decisions related to content, pedagogy and technology within their unique teaching contexts. Teachers therefore need to be able to problem solve and think creatively about the interactions described by the TPACK framework in order to maintain the equilibrium of the overall system.

It might be argued that good learning outcomes for school students ensue from a teacher's ability to maintain the equilibrium that is the TPACK system in 21st century classrooms. It might be argued further that teacher education programs that compartmentalise the three knowledge bases described by the framework (technology, pedagogy & content) and attempt to develop them separately from or in parallel with each other, undersell the value to be gained from using an integrated approach that requires the teachers in training to "think to learn and thereby learn to think" (Sternberg, 1999, p. 7) in relation to transforming pedagogy and content with technology.

Clearly, the conceptualization of the TPACK framework as a system suggests strongly that no one element is more or less important than the others but that they are interdependent. In previous decades it was sometimes assumed that it would be sufficient to graduate technology-competent new teachers and expect them to apply their skills in the classroom. That is no longer sufficient. Australia is progressing towards an understanding of the necessary skills for teachers to make them 'TPACK ready' for their professions and, as a first step, most Australian States and Territories have developed standards for teachers, including standards which refer to ICT. For example, the ten professional standards developed by the Queensland College of Teachers (2009) refer to ICT capabilities, along with references to pedagogical content knowledge. However, there is still much to be done to ensure that teacher educators and teacher education programs are ready and able to assist their students, soon to be teachers, to develop the new TPACK literacy that they will require in order to be able to facilitate and inspire student learning and creativity; design and develop digital-age learning experiences and assessments; model digital-age work and learning; promote and model digital citizenship and responsibility; and engage in professional growth and leadership (International Society for Technology in Education, 2008).

Generational change and the DER

One of the prevailing myths of our age is that there is a generational gap related to ICT such that the rising generations are 'digital natives' in contrast to their elders who are 'digital immigrants' (Prensky, 2001). Researchers report that students are "media literate" (Dodge, et al., 2008) and suggest that the solution to increased use of ICT in education is for educators to harness the skills of their technologically competent students (Harris & Rea, 2009). When teachers' use of ICT in classrooms appears limited, proponents of the digital generation gap are inclined to explain it in terms of the generational difference between teacher and student. In that view, a solution to the problem lies in generational change so that new teachers will use the new technologies. However, recent research has questioned the existence of the generational gap in relation to ICT (Margaryan, Littlejohn, & Vojt, 2011; Salajan, Schönwetter, & Cleghorn, 2010).

Australian university undergraduate cohorts, including those in teacher preparation programs, are not uniformly drawn from the new generation of school leavers. Most cohorts now include a variable, but sometimes substantial, proportion of mature students seeking career change opportunities. Of students studying for a Bachelors degree in Australian universities during 2009, 24% were aged 25 or older including 15% who were older than 30 years (DEEWR, 2010b). A survey of final year teacher education students found 45% were aged 25 or older and 10% were aged 40 or older (DEST, 2006). The presence of mature students in teacher preparation programs has many potential benefits but it makes any hope that a generational change in graduates entering the teaching profession will result in any desired changes in the uptake of ICT by teachers questionable.

Preparing teachers for the DER

If the Australian Digital Education Revolution is to be successful in achieving its goals, it will be necessary to ensure that newly graduating teachers are well prepared to make effective use of ICT in their future practice. For the reasons noted above, relying upon generational change is unlikely to provide a solution. Hence, it is important that teacher preparation programs respond to the need by adapting their curriculum and pedagogy. The *Teaching Teachers for the Future* project is intended to catalyse those changes.

The adoption of TPACK as the conceptual framework for TTF signals a clear understanding that the future of ICT in education cannot be based simply upon enhancing teachers' ICT capabilities whether through generational change or preparation programs. In the TTF project, as in professional practice, technology, pedagogy and content (curriculum) will be interlinked to create the complex professional knowledge that is

TPACK. However, as is evident in the TPACK model, the knowledge in the intersections of the domains does not exist independently of the knowledge characteristic of each domain. It is not possible to teach content or technology without demonstrating pedagogy in the process and neither can technology be learned effectively without using it, which necessarily involves dealing with content and learning something about pedagogy as a side effect of the process. There will be a continuing requirement for specialized knowledge of content (curriculum), pedagogy and technology but it is important to recognize that knowledge is interlinked across the domains, is developed in combination, and may be rearranged and applied in different combinations.

In the case of technology knowledge, it will be important that graduates have skills for the fluent use of a variety of ICT hardware and software and have the capability to learn more as the need arises and as technology continues to evolve. Teacher preparation programs seeking to enhance graduates' ICT capabilities will benefit from availability of data about students' access to ICT and existing capabilities with current and evolving software applications to inform their provisions so that programs neither needlessly replicate prior experiences nor assume too much as a foundation on which to build. This paper reports such data for a sample of students in the teacher preparation programs at a regional Australian university. It will seek to provide answers to the following research questions:

1. What levels of access do teacher candidates have to ICT hardware and services?
2. What levels of confidence do teacher candidates report for use of a variety of ICT applications?
3. What, if any, differences are found for responses of teacher candidates from different age groups (generations) or other identifiable groups?

Method

The data reported in this paper were collected as part of a larger study conducted as an extension of previous work on auditing the TPACK confidence of teacher preparation candidates (Albion, Jamieson-Proctor, et al., 2010; Jamieson-Proctor, et al., 2010). The instrument used was adapted from that used in the previous study and reported in those papers with the addition of an item about access to ICT based on one originally reported by Kennedy et al. (2009) and adapted for use elsewhere (Albion, Loch, Mula, & Maroulis, 2010).

The questionnaire was administered online using LimeSurvey® (http://www.limesurvey.org/) with email invitations sent to 3200 students enrolled in teacher preparation programs at two participating universities in Queensland. One of the universities is located in a largely urban area and the other is classified as a regional university. The survey software supported anonymous tracking of responses so that reminders could be sent to students who had not responded. Two rounds of reminders were sent during the October-November 2010 period in which the survey was active. Data were downloaded and transferred to PASW Statistics 18 for analysis.

Results

The questionnaire recorded a total of 891 responses (28%) from the 3200 invitations sent to students at the two universities. Some students exited the questionnaire without completing it and, because the data were collected to guide internal university operations as well as for research, the final question sought student consent to use the data for research, further reducing the data available for analysis. This paper reports on data from 450 completed questionnaires that included research consent received from the 2170 invited students (21% response) at the regional university.

Table 1 presents data for gender and age of survey respondents. As is common in teacher preparation programs, the vast majority of respondents were female (86%). This proportion is somewhat higher than the 80% reported from a national study of final year teacher education students (DEST, 2006). Slightly more than half (58%) of the respondents reported being aged 30 years or older, confirming that the teachers in preparation at this regional university could not be presumed to be members of the 'digital natives generation'. This proportion is higher than the approximately 30% reported from a national study of final year teacher education students

(DEST, 2006) but is representative of the teacher preparation enrolment at the study university.

Table 1: Percentage distribution of respondents by gender and age (N = 450)

	< 20	20-29	30-39	40-49	>=50	Total
Female	7.3	29.3	28.9	16.7	4.0	86.2
Male	1.6	4.2	3.6	4.4	0.0	13.8
Total	8.9	33.6	32.4	21.1	4.0	100.0

The regional university delivers its teacher preparation programs on three campuses as well as fully online. Responses to the questionnaire represented all four locations, with 27% reporting that they were studying at the main campus located in a provincial city, 9% at the smaller regional campus, 12% at the newer outer-metropolitan campus, and 52% studying predominantly online. Respondents were distributed across all years of the four-year teacher preparation program with 35% in first year, 23% in second year, 26% in third year, and 16% in fourth year. In respect of these general demographic variables the respondents appear to be representative of the population of the teacher preparation program more broadly.

Table 2: Percentage of respondents reporting different levels of access to types of ICT (N = 450)

	Access exclusively for my own use	Access any time I need it, shared with other people	Limited or inconvenient access	No access	Not sure	χ^2 statistics for differences by age (df = 16)		
						χ^2	*p*	V
Desktop computer	40.2	37.6	8.2	13.3	0.7	15.66	.477	.093
Portable computer	68.4	14.4	3.6	13.1	0.4	27.20	.039	.123
MP3 player	54.4	10.2	5.1	28.4	1.8	64.32	< .001	.189
Video MP3 player	29.3	6.4	6.7	54.2	3.3	37.90	.002	.145
iPod Touch	13.8	5.1	4.7	74.2	2.2	19.51	.243	.104
Digital still camera	69.3	21.6	2.0	6.2	0.9	29.46	.021	.128
Digital video camera	34.2	20.0	10.0	34.0	1.8	25.34	.064	.119
Mobile phone	75.8	4.7	3.3	14.9	1.3	19.04	.267	.103
Smart phone	24.2	1.8	3.1	67.8	3.1	20.18	.212	.106
Portable data storage	92.4	3.6	0.4	2.9	0.7	15.58	.482	.093
Video game console	30.0	34.2	6.2	28.2	1.3	36.34	.003	.142
Web cam	53.8	15.1	4.9	23.8	2.4	18.12	.317	.100
Printer	65.6	31.1	2.4	0.4	0.4	33.55	.006	.137
Scanner	57.3	28.9	6.9	6.4	0.4	24.58	.078	.117
eBook reader	3.8	2.9	4.0	85.6	3.8	16.14	.443	.095
iPad	2.2	2.2	2.2	90.0	3.3	22.92	.116	.113
Dial-up Internet	6.4	4.2	4.4	80.9	4.0	37.03	.002	.143
Broadband Internet	63.8	31.8	2.0	2.2	0.2	39.22	.001	.148

Participants were asked to indicate their levels of access to different types of ICT. Where appropriate, to assist interpretation, the items included examples such as “iPhone, Android, Blackberry” for smartphones or “Kindle, Kobo, iPad” for eBook reader. Table 2 reports these data as percentages of responses in each category for all respondents.

When the data for desktop and portable computer access were examined together, just 2 respondents (0.4%) reported no access to either and 5 respondents (1%) reported that they had no access or only limited or inconvenient access to a computer. In all, 278 respondents (62%) reported that they had exclusive or convenient shared access to both desktop and portable computers. In regard to Internet access, just 8 respondents (1.8%) reported limited, inconvenient or no access to either dial-up or broadband connections and only 11 respondents (2.5%) with dial-up access did not also have convenient access to broadband. Of the 440 respondents (2.2%) who reported some level of broadband access, 202 (46%) reported that the quality of the service they accessed, in speed and data capacity, was acceptable with most reporting speeds of 512 kbps or better and data capacity of at least 5 GB per month or speeds and data volume they considered acceptable for their purposes.

These high levels of access to basic forms of ICT contrast with more limited access to newer forms of ICT such as eBook readers (86% no access), basic MP3 players (28% no access) and MP3 players able to play video (54% no access) that might have application for access to study material. Although a small proportion of these students may be equipped to take advantage of study materials packaged for mobile access, many or most are not and this should be considered as a factor in future development of instructional materials.

The responses were further examined using cross-tabulation with age and statistics from the associated chi-squared tests are also reported in Table 2. Numbers of responses and degrees of freedom did not vary and are not reported in the columns. Cramer's V is included as a measure of effect size. The chi-squared tests found significant differences by age ($p < .05$) for MP3 players (with and without video playing capability), video game consoles, printers, Internet connections (dial-up and broadband), digital cameras, and portable computers. All of the effect sizes as measured by Cramer's V are small (< .2) and, other than for the MP3 players, game consoles, and portable computers, where there was a clear pattern of higher levels of access among younger respondents, the patterns of different access levels by age were unclear. There were some indications that the differences for printers and Internet connections might be related to higher levels of exclusive access among older respondents but there were also higher numbers of older respondents who reported being unsure of their access to those forms of ICT. On the basis of these results, other than for a small subset of devices (MP3 players, games consoles) typically associated with the younger generation and portable computers, there appears to be limited evidence of a significant generational gap in access to ICT among these teachers in preparation.

Table 3: Percentage distribution and means of confidence for ICT applications (N = 450)

	No confidence (1)	Some confidence (2)	Confident (3)	Very confident (4)	Mean	SD	ANOVA statistics for differences by age		
							F	***p***	**η^2**

Create reusable learning objects	26.2	39.1	23.8	10.9	2.19	0.95	3.16	.014	.028
Access repositories of reusable learning objects	28.4	35.8	22.9	12.9	2.20	1.00	2.71	.030	.024

Participants were asked to rate their confidence for using various types of ICT applications. To assist with clarifying meaning, examples of applications were provided for each item but they are omitted from the table for reasons of space. Responses were recorded on a 4-point scale from ‘No confidence’ to ‘Very confident’ and means and standard deviations were calculated by scoring the points from 1 to 4. Table 3 reports these data as percentages of responses in each category together with means and standard deviations.

Results indicated that the students were confident to very confident with common applications such as word processing, email, and web browsing. However, most respondents were not confident with less commonly used or more complex ICT applications such as spreadsheets, databases, multimedia development, web page development, and video editing. These results are consistent with the finding reported in the earlier study (Jamieson-Proctor, et al., 2010) which reported that final year students tended to be confident in only a limited range of ICT applications, such as word processing, email and web browsing. Similarly, many were not confident in using applications that might be used to enhance learning and teaching, such as accessing repositories of learning objects, online publishing, and visual thinking software.

The results were examined using ANOVA for differences by age group and the relevant statistics are also reported in Table 3. Numbers of responses and degrees of freedom were consistent at 450 and (4, 445) across all items. Eta squared (η^2) is included as an estimate of effect size. Analysis using ANOVA found significant differences ($p < .05$) by age group for 13 of the 21 application categories as shown in Table 3. Post hoc analysis using Tukey HSD revealed that the significant differences in means were related to respondents in the 40 to 49 years age group and, less often, the 30 to 39 years group, reporting lower levels of confidence than those in the 20 to 39 years and less than 20 years age groups. In all cases the effect sizes given by η^2 were small (< .2). Although the effect sizes are small, the pattern of results suggests that, in addition to the whole population of teachers in preparation having limited confidence with newer ICT applications, there may be some specific differences related to age that should be considered in the design and implementation of teacher education programs.

A further ANOVA was used to investigate any relationship between confidence with ICT applications and progression in the teacher preparation program. Significant differences were found for presentation software ($F(3,425) = 16.24$, $p < .001$, $\eta^2 = .103$), visual thinking and concept mapping ($F(3,425) = 5.42$, $p = .001$, $\eta^2 = .037$), and accessing learning object repositories ($F(3,425) = 11.87$, $p < .001$, $\eta^2 = .077$). In each case students in later years of the program reported higher mean levels of confidence. For presentation software and access to learning object repositories there was a pattern of growth from year to year whereas for visual thinking software there was a more pronounced increase for respondents in their fourth year.

Discussion

The analysis presented in this paper was intended to address three key questions related to levels of access to ICT hardware and services, confidence for using ICT applications, and related differences by age or year of study. Most of the teachers in preparation who responded to the questionnaire have convenient access to basic ICT hardware and services and are confident in working with common ICT applications. However, their experience of increasingly common forms of ICT and software applications appears to be more limited. Many reported having little or no access to devices such as MP3 players, especially those with capability to view video, digital video cameras, smart phones or similar devices such as the iPod Touch, or eBook readers. Similarly, low levels of confidence were recorded for some ICT applications, especially those that are in less common use or are more complex, such as authoring multimedia or web pages.

Analysis revealed some areas in which there were significant differences by age group for access to different forms of ICT and confidence in using some applications. However, the effect sizes were small. Although it would not be appropriate to assume age-related differences as a basis for program planning, it would be important to recognize that such differences in access, related experience, and confidence do exist between and within age groups and to ensure that any teacher preparation program offers opportunities for access that will assist students to extend their experience of ICT and build their confidence with a wider range of applications. There is limited evidence of growth in confidence with some ICT applications from year to year within the program but there remains ample scope for further development of opportunities.

When considered alongside broader trends in ICT and its adoption in Australian society these findings have implications for the design and implementation of teacher preparation programs. ICT, both hardware and software, continues to develop quickly and the uptake by households is widespread. Among Australian households with children the proportion with Internet connected computers grew from 20% to 86% between 1998 and 2009 (ABS, 2011). In 2009 31% of children owned a mobile phone with the proportion varying from 2% for 5-8 year olds to 76% among 12-14 year olds (ABS, 2011). Although only 4% of children had used their mobile phone to access the Internet, that proportion can be expected to increase rapidly as Internet-connected smartphones become more common. Similar trends exist for other forms of ICT. The implication is that the ICT capabilities required by teachers will be a moving target and teacher preparation programs need to respond by ensuring that graduates have had opportunities to develop skills and confidence for working with newer forms of ICT that are likely to be increasingly familiar to the children they will be teaching and to continue learning about new forms of ICT beyond graduation. It will not be sufficient to rely upon the skills that teacher candidates possess on entry or to address only the forms of ICT that are most commonly available during their program of study.

The *Teaching Teachers for the Future* project is directed toward the development of graduating teachers' TPACK, which, as indicated in Figure 1, is a complex construct comprising the intersection of different knowledge domains. Given that complexity, the successful development of TPACK will not be accomplished by developing separate strands of content, pedagogical and technological knowledge and expecting those to be appropriately melded in the future practice of graduates. As noted above, it is not possible to teach content without demonstrating pedagogy nor to learn technology without using it with content and observing pedagogy in the process. Nevertheless, data such as presented in this paper, about the current access of teacher candidates to ICT and their confidence for using them, provide an important foundation for guiding the development of teacher preparation programs.

An important element of the TTF project is the auditing of teacher preparation programs to determine how ICT is integrated and presented in various elements of the program. The information from the audit is intended to provide a basis for planning appropriate changes that will enhance the ICT capabilities of graduates. In doing so it will be important to ensure that teacher preparation programs include ample opportunities for students to experience working with a variety of ICT devices and applications using content from the curriculum areas in a variety of pedagogical modes. No doubt such opportunities already exist in some sections of the programs and it will be important to identify, recognize, and preserve existing effective elements. It will be equally necessary to identify what opportunities are missing and to provide those in ways that model the effective application of TPACK and provide both models for students to emulate and the experience from which to build their own TPACK. If *technology* in TPACK is understood in the way advocated by Cox (2008) with an emphasis placed on *emerging* ICT, then it will be important to ensure that programs are designed so that they can continue to evolve by offering students opportunities to work with new ICT both in curriculum areas, for development of TCK, and in pedagogy, for development of TPK. This requirement will challenge teacher preparation programs to find the means to support and encourage teacher educators to work at the intersections of new ICT with both content and pedagogy.

In the case of the regional university in which this study was located, the audit of subjects in the program is considering how ICT is used to help students understand the concepts in a course, how it is used to contribute to course delivery and assessment, and the degree to which the ICT pedagogy used in the course is made explicit to the students. The latter is important for ensuring that graduates develop appropriate insights into how and why they might use ICT in their own classrooms. The results of the audit, being facilitated by the experts funded by the TTF project, will be used as the basis for discussion about how courses might be revised to contribute more effectively to the development of graduates' ICT capability. Initial results of the audit have been encouraging. Possibly as a consequence of teacher preparation courses having been offered online in recent years, academics responsible for designing and implementing courses demonstrate willingness to consider new approaches and courses are already incorporating ICT in ways that facilitate development of relevant capabilities in graduates. Data such as that reported in this paper will be used to inform decisions about the relative ease with which students may be able to participate in activities requiring access to specific forms of ICT, and about the need to include opportunities for some or all students to develop experience with specific ICT.

Learning Object Evaluation Metrics Based on Learning Styles Theory

Ali Alharbi, **Frans Henskens and Michael Hannaford**
School of Electrical Engineering and Computer Science,
The University of Newcastle, Australia

This poster presents evaluation metrics to assess learning objects in terms of their compatibility with different learning styles. The metrics allow learning objects to be ranked based on their effectiveness with different types of students which, in turn, can facilitate designing and searching for learning objects that meet the learner's requirements and preferences.

Keywords: learning object, learning style, evaluation metrics.

Introduction

Learning objects can be defined as "any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning" (LTSC, 2002). Lecture slides, simulations and textbooks can all be examples of learning objects.

Finding learning objects that meet students' preferences is one of the major problems that may prevent students from using learning objects (Sanz-Rodríguez, Dodero, & Sánchez-Alonso, 2010). This poster proposes evaluation metrics to ensure the compatibility of learning objects with different learning styles. The metrics can be used to guide the instructional design process to ensure that the learning materials provide equal experience for students with different learning styles. The metrics can also be used in learning object repositories to rank the materials based on their compatibility with different learning styles.

Theoretical Background

A learning style is "a particular way in which an individual learns" (Pritchard, 2009). There are different models to describe learning styles. The Felder–Silverman Learning Style Model (Felder & Silverman, 1988) is a famous example which was developed to describe learning styles in four dimensions.

The first dimension concerns information perception. This dimension distinguishes between *sensing* learners who prefer concrete information and facts, and *intuitive* learners who prefer abstract concepts and theories. Sensing learners tend to link the learning material to the real world and prefer to solve problems using well-established methods. In contrast, intuitive learners tend to look for possibilities and try to find innovative methods of solving problems.

The second dimension is associated with information processing. It distinguishes between *active* and *reflective* learners. Active learners prefer to try something out to see how it works while reflective learners prefer to think something through before making an attempt. Intuitive learners spend more time observing how other people perform a task while active learners tend to practically experiment to understand the new information.

The third dimension describes the way people prefer to receive information. *Visual* learners prefer to use visual media, such as images, diagrams, and animations, to represent information. In contrast, *verbal* learners prefer information in a written or spoken form.

The fourth dimension is associated with information organization. *Sequential* learners prefer to progress in a logical, step-by-step approach, moving from the parts to the whole. *Global* learners prefer to see the big picture before going into the details, using a more holistic approach, without following a sequential path.

Learning Object Evaluation Metrics

The proposed metrics are classified on a number of scales, described below. Each scale represents one dimension of the learning style model. The content of the learning objects should be designed to support the metrics provided in each scale.

Level of Abstraction

This scale evaluates learning objects based on the type of information that they present. The content of the learning object can be either completely abstract, with no link to the real world, or it can be facts, consisting of concrete concepts. To make sure that the content meets the needs of the different learning styles, there should be a balance between the levels of abstraction used in the learning objects. This scale suggests evaluation metrics such as the use of *real world examples* and *analogies*, *facts*, *step-by-step procedures*, and *experimental results*. In contrast, for those who prefer abstract concepts over facts, the leaning objects may contain *mathematical formulas*, *program codes*, *theories*, *puzzles* or *innovative ideas*.

Medium of Presentation

This scale evaluates learning object based on the medium of presentation of the learning object content. The content should be presented visually, using pictures, diagrams or animations. Further, for each visual medium, enough textual or spoken explanations should be provided to support verbal learners. This scale could then use evaluation metrics such as the use of *pictures*, *charts*, *diagrams*, *animations*, *videos* and the use of *text*, *detail* and *audio*.

Interactivity Level

This scale evaluates learning object based on the level of interactivity supported by the learning object. The learning object can support high levels of interaction with the learners by providing features such as *interactive simulations*, *self-assessment exercises* and *discussions*. To support learners with low preference toward interactivity, the learning object may contain *exercises with model answers*, *reflections* and *ratings* of the learning objects.

Sequencing and Structure

This scale evaluates learning objects based on organization of the content of the material. Balance should be kept between sequential and global organization of information. Sequential support can be achieved by providing *outline* and *overview* components of the learning object. To support global learners, information related to *prerequisite knowledge* and *comparison* with other learning objects should be provided.

Conclusions and Future Work

This poster presented evaluation metrics to assess the compatibility of learning objects with different learning styles. The metrics can be used by instructional designers and teachers to ensure that the learning material provides an equal experience for students with different learning styles. It can also be used in e-learning systems to recommend appropriate learning objects for learners. In the future, these metrics will be integrated into the design of a new learning object repository to help improve the quality of learning objects during the authoring process.

An Investigation into the Learning Styles and Self-Regulated Learning Strategies for Computer Science Students

Ali Alharbi, **David Paul, Frans Henskens and Michael Hannaford**
School of Electrical Engineering and Computer Science,
The University of Newcastle, Australia

Student-centred educational paradigms place a high level of responsibility on learners to control and self-regulate their personal learning processes. In these new educational paradigms, it is essential to understand students' preferences and the self-regulated learning strategies they use in order to enhance the learning process. This paper examines the different learning styles and self-regulated learning strategies used by students in a core computer science course. An Index of Learning Styles and a Self-Regulated Learning Strategies Questionnaire were administered to second year students studying programming languages concepts and paradigms. Results show that aspects of students' preferred learning styles had a significant impact on academic performance in the midterm examination. Further, consideration of the self-regulated learning strategies used by students provides evidence that metacognitive strategies were the least popular strategies among students. This suggests that students are not aware of important self-regulated learning strategies and may benefit from educational interventions focusing on these strategies. These results have implications for future teaching of the course, and are being used to guide the development of an online collaborative learning objects repository that aims to improve self-directed student learning.

Keywords: learning styles, self-regulated learning, computer science education

Introduction

The recommended educational paradigm has shifted from being teacher-centred to being more student-centred, with each student taking greater responsibility for his or her own learning process (Berglund, et al., 2009). Since every student has different learning preferences, it is important that course material is presented in such a way that no student is unfairly disadvantaged. To ensure an equal experience for all students, it is necessary to understand the learning preferences and strategies of the students being taught. Adopting a specific teaching method without considering the diverse needs of the group being taught can result in an inefficient learning outcome for some students (Pritchard, 2009). Thus, when presenting learning material to students, it is important that all student learning styles are supported. Further, the interaction between the learners and the learning material should be taken into consideration to improve the quality of the learning material over time.

Researchers have only recently started investigating educational aspects to improve the learning and teaching of computer science (Haden, Fincher, & Petre, 2004). In computer science courses, very few students share the same learning styles as their instructors (de Raadt & Simon, 2011). Thus, instructors cannot wholly rely on their own learning styles when developing learning material for their students. However, studies that investigate the learning styles of students in computer science courses are limited (de Raadt & Simon, 2011). Further, these studies focus only on students' learning styles, isolated from other aspects of student-centred educational paradigms, such as the cognitive and social aspects of teaching and learning. Education theories that combine cognitive and social aspects of learning can help provide a framework leading to a greater understanding of students' preferences and introducing a new direction for research and design of learning material in computer science education (Ben-Ari, 2004; Machanick, 2007).

This paper describes the diversity and influence of learning styles and self-regulated learning strategies for students enrolled in the core computer science course entitled "Programming Languages and Paradigms" at The University of Newcastle. This provides a case study for computer science education, and is being used to aid the development of an online collaborative learning object repository that assists students by evaluating their preferred learning style and directing them to the materials that they should find most useful. The aim of the study is to provide a baseline to assist the design and allow the evaluation of the effectiveness of a new online collaborative learning objects repository. This study is guided by the following questions:

1. What aspects of learning styles can be found in a typical computer science course?
2. What is the degree of use of different self-regulated learning strategies by students in the course?
3. What is the influence of students' learning styles on their academic performance in the course?
4. What self-regulated learning strategies have the most influence and need more focus?
5. How can the results of this study be combined with contemporary education paradigms to provide a framework for building a collaborative learning object repository to improve the next iteration of the course?

Theoretical Background

Different students perceive and process information in different ways (Shaw & Marlow, 1999). A student's preferred learning style is one of the main individual differences that effects how the student approaches new knowledge. Another important factor is the student's use of various self-regulated learning strategies. This section provides a brief introduction to learning style theory and self-regulated learning, and relates the theories to education in computer science.

Learning Style Theory

Learning is the process by which individuals acquire new knowledge. Each individual is different, so every student approaches the learning environment in a different way. A learning style is "the characteristic cognitive, affective and psychological behaviours that serve as relatively stable indicators of how learners perceive, interact with and respond to the learning environment." (Keefe, 1988). Learning styles are not fixed, and learners can adopt a different learning style depending on the subject matter and current learning environment (Pritchard, 2009). However, students do typically have one learning style that is preferred over others and can be motivated by learning material compatible with this preference (Larkin & Budny, 2005). Knowledge of their preferred learning styles can be used to help guide students to choose the best learning strategies, and allow teachers to modify their instructional strategies to provide the greatest opportunity for all students to learn.

This paper uses the Felder-Silverman Learning Style model (Felder & Silverman, 1988), a popular model to identify learning styles in science and engineering education. It is used for both traditional and technology-supported learning, and consists of the following four dimensions:

Perception (Sensing or Intuitive) describes the ways in which learners tend to perceive information. Sensing learners prefer to learn facts, are comfortable with details, and tend to solve problems using well-established methods. Intuitive learners prefer abstract concepts, theories, and mathematical formulas, and seek innovation and new ideas when solving problems.

Input (Visual or Verbal) distinguishes between learners based on their preferred medium for the presentation of information. Visual learners prefer to learn using visual medium of presentations, such as pictures, charts, and diagrams. Verbal learners prefer spoken or written materials. Both types of learners benefit when material is delivered using a combination of visual, verbal, and written forms (Mills, Ayre, Hands, & Carden, 2010).

Processing (Active or Reflective) evaluates learners based on the way they process information. Active learners prefer to learn material by using it, whereas reflective learners prefer to think about how things work before actually trying them out. Active learners are typically more comfortable working in groups than reflective learners.

Understanding (Sequential or Global) looks at how users understand new information. Sequential learners like to follow a step-by-step linear approach that focuses on the connections between the different parts of the learning material. Global learners prefer to grasp the full picture before narrowing into the details.

Self-Regulated Learning

In student-centred educational paradigms, it is essential for learners to control and regulate their individual learning processes (Chen, 2002). Self-regulated learning is an educational theory influenced by constructivism theory (Ben-Ari, 1998) and social learning (Bandura, 2001). Self-regulated learners are characterized by their ability to be "metacognitively, motivationally, and behaviourally active participants in their own learning process" (Zimmerman, 1986). Metacognition refers to an individual's awareness and control of the cognition process and includes processes such as goal setting, planning and self-evaluation used to control and monitor the individual's learning process (Pintrich, 1999). While there are various models of self-regulated learning (Curry, 1983), they all share some main assumptions (Pintrich, 2004). Firstly, the learner is considered to be an active participant in the learning process rather than a passive receiver of knowledge. Secondly, it is possible for the learner to control, monitor and self-regulate some of the learning process. Finally, the learner has a goal and the learning process can be evaluated to determine whether the current learning process will reach that goal, or whether a change is required. Learners can improve their learning strategies through a variety of different techniques. These techniques fall into the following categories (Pintrich & De Groot, 1990):

Cognitive learning strategies are methods used by the learner to deal with the actual learning material. Elaboration methods, such as summarizing, paraphrasing and relating new information to existing knowledge is one cognitive strategy that has a positive impact on the academic performance of students (Pintrich & De Groot, 1990). Other examples are organisational strategies, which involve creating hierarchies of presented information to make it easier for the learner to connect related concepts, and critical thinking, which evaluates the creditability of the learning material and attempts to apply the concepts under study to new situations.

Metacognitive learning strategies are based around the learner's knowledge and self-regulation of their own cognition through planning and monitoring of their cognitive learning activities (Pintrich, 1999). Planning involves setting goals and generating questions to guide study and make the learning process easier. Monitoring strategies include self-assessment to verify the learner's understanding of the material.

Resource management strategies require the learners to take control of their learning environment. This includes management of time and study environment. Another important aspect is the management of who to include in the study environment; being able to seek help and learn from peers are important characteristics of a self-regulated learner (Ryan & Pintrich, 1997).

Computer Science Education

Teaching and learning of computer science concepts are challenging tasks for both teachers and students (Ben-Ari, 1998). Computer science involves studying dynamic and abstract concepts that are difficult for students to understand using traditional teaching and learning methods. Further, computer science is a rapidly changing area, which is driven by newly emerging technologies rather than the pedagogy (Holmboe, McIver, & George, 2001). "Only recently have CS educators begun to explore important issues and methodologies in computer science teaching" (Haden, et al., 2004). Computer science education research is still in its infancy and there are many initiatives to apply different learning theories to improve computer science education.

In the last few years, student-centred approaches to learning have received some attention in computer science education. These approaches focus on the role of the learners to discover and construct knowledge through active participation in the learning process. This new view of learning is related to some extent to the theory of constructivism (von Glasersfeld, 1997). Constructivism theory has particularly influenced mathematics and science education, and in the last few years computer science education research has investigated the role of constructivism as a theoretical basis of computer science education (Ben-Ari, 1998).There have been a number of educational approaches and software proposals based on the theory of constructivism. Problem-based learning, in particular, is a technique based on constructivism that has been found useful in computer science education. However, constructivism accounts only for cognitive aspects of learning and neglects, to some extent, the social dimension of learning. Cognitive-based models are not enough to describe the learning process (Machanick, 2007), so new models are required for computer science education. In particular, there is a need for models that include the social aspects of learning.

There have been some previous studies to investigate the learning styles of computer science students. Thomas et al. (2002) investigated the learning styles of students enrolled in an introductory programming course. The majority of students in the study were assessed as sensing, visual, reflective and sequential. The result of the study indicated that, in the exam portion of the course, significant differences were detected in students' performance between reflective and active learners in favour of reflective learners, and between verbal and visual learners in favour of verbal learners. One interesting result of the study was that although the majority of students were visual learners, verbal learners had the highest performance in the course. This result is consistent with the results reported in (Chamillard & Karolick, 1999) and (Allert, 2004). In a recent study, de Raadt and Simon (2011) stated that there is a scarcity of research in the exploration of learning styles in computer science education. Motivated by this, they conducted a study to investigate students' learning styles, again in an introductory programming course. The study found that the majority of students preferred practical applications and concrete information connected to reality and were comfortable with details. They prefer to learn using simulation and case studies. The study concluded that learning materials do not have to cover all possible learning styles but "at least provide one usable thing for each student" (de Raadt & Simon, 2011).

The existing studies of learning styles in computer science education have investigated aspects of learning styles independently of other pedagogical factors, such as the strategies used by students when presented with learning material. While the results are interesting, they do not suggest how they can be integrated with other contemporary learning theories to improve the learning process. Further, the studies mentioned do not indicate the strength of the students' learning style preferences, making it difficult to determine which aspects of learning styles require greater focus. Self-regulated learning models can explain not only cognitive aspects of learning but social aspects as well. Thus, an investigation into the learning styles and self-regulated learning strategies of students can be combined to help provide a framework upon which educational interventions can be built. This study presents an investigation into the learning styles and self-regulated learning strategies of computer science students to assist with the design of a collaborative learning object repository for use in future iterations of the course, and to provide a baseline to test the effectiveness of the new system.

Research Method

The purpose of this study was to evaluate the learning styles and self-regulated learning techniques used by computer science students as a necessary step towards the improvement of teaching and learning methods of a computer science course. This required the collection and analysis of data from computer science and software engineering students. In this section we describe the participants used in the study, the data collected from them, and how the data has been analysed.

Participants

Participants were 38 students enrolled in the "Programming Languages and Paradigms" course taught at the University of Newcastle, Australia, in the first semester of 2011. This is a compulsory second year course for undergraduate students enrolled in the computer science and software engineering programs. The course covers the theory behind the design and implementation of programming languages, recognised as an integral part of any computer science or software engineering degree (IEEE/ACM, 2005). The course follows a traditional teaching method consisting of weekly lectures and workshops. The instructor covers the theoretical concepts of the course in the lectures using PowerPoint slides that have been prepared based on cumulative experience from teaching the course for the last few years. The workshops provide hands-on exercises to show students how the concepts covered in the lectures are applied in practice. Interaction between students and instructors outside of the formal face-to-face sessions is supported through the Blackboard learning management system. Students have to complete three individual practical assignments throughout the course, as well as written midterm and final exams. This study uses the midterm exam as a way to measure students' performance in the course.

Data Collection Instruments

Data was collected from participants immediately before they sat the midterm examination for the course. The Index of Learning Styles (Felder & Soloman, 1997) was used to identify each student's learning style according to the Felder-Silverman model. This was followed by a questionnaire based on the Motivated Strategies for Learning Questionnaire (Pintrich, Smith, Garcia, & McKeachie, 1991) to evaluate the self-regulated learning strategies used by the participants.

The Index of Learning Style comprises 44 items that present the participant with a situation and two possible options, asking the participant to choose the option that best represents him or her. There is a total of 11 items for each of the four dimensions of the Felder-Silverman model; these rank participants as either sensing or intuitive, visual or verbal, active or reflective, and sequential or global learners. The self-regulated learning strategies questionnaire consists of 30 items that ask the participant to indicate the extent to which a certain statement applies to the participant using a seven-point Likert scale ranging from “Very true of me” to “Not at all true of me”. The questionnaire determines the extent to which the participant utilizes the six self-regulated learning strategies of elaboration; organization; critical thinking; metacognition; peer learning and help seeking; and e-learning resource management. Students’ academic performance was measured using the midterm exam scores. The exam is a traditional paper-based assessment in which students have to respond to different questions that cover a number of modules studied in the course.

Data Analysis

Descriptive analysis was conducted using the mean, standard deviation, and charts to examine the study variables. A correlation analysis between the study variables was then performed using Pearson’s product moment correlation coefficient. Finally independent samples t-tests were used to investigate the difference in midterm exam scores between students with different learning styles.

Results

This section describes the analysis of the data collected for this study. The results for the various learning styles used by the students are presented first, followed by an investigation of the relationships between the reported self-regulated learning strategies.

Student Learning Styles

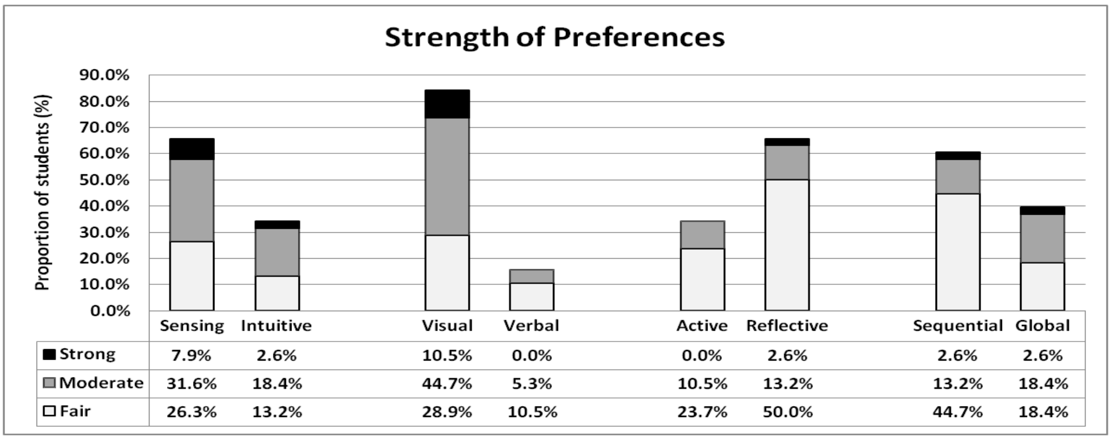

Figure 1: Distribution of students based on the strength of their learning style preferences.

The columns in Figure 1 show the students’ learning styles in the four dimensions of the Felder-Silverman Learning Styles model. In the perception dimension (sensing/intuitive), the majority of students (65.8%) were sensing learners, while 34.2% were intuitive learners. The input dimension (visual/verbal) showed an even greater one-way preference with 84.2% of students being identified as visual learners, and only 15.8% as verbal learners. In the processing dimension (active/reflective), 65.8% were reflective learners and 34.2% were active learners. Finally, in the understating dimension (sequential/global), the proportions of sequential and global learners were 60.5% and 39.5% respectively.

A deeper analysis, also depicted in Figure 1, examined the strength of a student’s learning style preference. Each dimension was subdivided into three levels: fair, moderate and strong. In the perception dimension (sensing/intuitive), 26.3% had a fair preference towards a sensing learning style and 13.2% had a fair preference towards an intuitive learning style. Together, this means that 39.5% of students were fairly balanced between the two learning styles. Of the remaining students, 39.5% had a moderate or strong preference towards a sensing learning style and 21.0% had a moderate or strong preference towards an intuitive learning style.

In the input dimension (visual/verbal), visual learners were dominant with 55.2% of students having either a moderate or strong preference towards using visual representations of the learning material. In contrast, only 5.3% of students had a moderate preference, and no students had a strong preference, towards a verbal learning style. In the processing dimension (active/reflective), the majority of students (73.7%) had a fairly balanced preference between the two learning styles, though reflective learning was more popular. Finally, in the understating dimension (sequential/global), while the majority of students were sequential learners, 63.1% had a fairly balanced preference between the two learning styles.

A correlation analysis to measure the relationship between learning style and academic performance is provided in Table 1, and t-tests that provide further insight are presented in Table 2. Two students were excluded from this part of the study because they did not complete the midterm examination. The correlation analysis shows that only the perception dimension had a significant impact on the students' results in the examination, with the t-tests confirming that sensing students (M=47.16, SD=15.50) were significantly outperformed by intuitive students (M=60.27, SD=14.94), t (34) = 2.364, $p < 0.05$.

Table 1: Correlation between learning style dimensions and midterm exam results (N=36).

Dimension	Pearson Correlation (r)	Significance (2-tailed) (p)
Perception (Sensing/Intuitive)	-0.349	0.037*
Input (Visual/Verbal)	-0.078	0.650
Processing (Active/Reflective)	-0.053	0.760
Understanding (Sequential/Global)	0.170	0.323
* Correlation is significant at the 0.05 level (2-tailed).		

Table 2: Mean comparison between different learning styles in midterm exam results.

Descriptive Statistics for exam results (Max=80)				Independent T-test		
Learning Style	**N**	**Mean**	**SD**	**t**	**df**	**Sig.**
Sensing	25	47.16	15.491	-2.364	34	.024*
Intuitive	11	60.27	14.940			
Visual	31	50.42	15.461	-.679	34	.501
Verbal	5	55.80	22.410			
Active	13	50.54	18.338	-.171	34	.865
Reflective	23	51.52	15.465			
Sequential	22	52.68	16.811	.694	34	.493
Global	14	48.79	15.788			
* Correlation is significant at the 0.05 level (2-tailed).						

In the other learning style dimensions, visual learners (*M*=50.42, *SD*=15.46) had slightly lower performance than verbal learners (*M*=55.80, *SD*=22.41), reflective learners (*M*=51.52, *SD*=15.47) slightly outperformed active learners (*M*=50.54, *SD*=18.33) and sequential learners (*M*=52.68, *SD*=16.81) did better than global learners (*M*=48.79, *SD*=15.79). However, in all of these dimensions, the difference was not statistically significant.

Student Self-Regulated Learning Strategies

Student's reported use of self-regulated learning is summarized in Table 3.

Table 3: Students' use of self-regulated learning strategies (N=38)

Self-Regulated Learning Strategies	Mean (Max=7)	Std. Deviation
Elaboration Strategies	4.55	0.91
Organizational Strategies	3.94	1.26
Critical Thinking Strategies	4.32	1.20
Metacognitive Strategies	3.92	0.90
Peer Learning and Help Seeking Strategies	4.02	1.53
E-Learning Resource Management Strategies	4.45	1.10

Students show a moderate use of each of the self-regulated learning strategies with elaboration and e-learning resource management strategies being the most popular. In contrast, metacognitive and organizational strategies were the least popular among the students.

Table 4: Correlation matrix of self-regulated learning strategies (N=38)

		1	2	3	4	5	6
1. Elaboration Strategies	Pearson Correlation (r)		.722**	.297*	.428**	.247	.286*
	Sig. (1-tailed)		.000	.035	.004	.067	.041
2. Organizational Strategies	Pearson Correlation (r)	.722**		.134	.472**	.158	.180
	Sig. (1-tailed)	.000		.210	.001	.172	.140
3. Critical Thinking Strategies	Pearson Correlation (r)	.297*	.134		.477**	.084	.291*
	Sig. (1-tailed)	.035	.210		.001	.308	.038
4. Metacognitive Strategies	Pearson Correlation (r)	.428**	.472**	.477**		-.067	.151
	Sig. (1-tailed)	.004	.001	.001		.345	.183

5. Peer Learning and Help Seeking	Pearson Correlation (r)	.247	.158	.084	-.067		.214
	Sig. (1-tailed)	.067	.172	.308	.345		.098
6. E-Learning Resource Management	Pearson Correlation (r)	.286*	.180	.291*	.151	.214	
	Sig. (1-tailed)	.041	.140	.038	.183	.098	
** Correlation is significant at the 0.01 level (1-tailed). * Correlation is significant at the 0.05 level (1-tailed).							

Table 4 presents the correlation matrix between the self-regulated learning variables used in this study. Results reveal a significant positive relationship between elaboration strategies and organizational strategies (r=0.72, p<0.01). This indicates that, as use of elaboration strategies increases, so too does the use of organizational strategies. There is also a highly significant positive relationship between metacognitive strategies and critical thinking strategies (r=0.48, p<0.01) and between metacognitive strategies and elaboration strategies (r=0.43, p<0.01) and between metacognitive strategies and organizational strategies (r=0.47, p<0.01).

Discussion

This section discusses implications of the results presented in the previous section.

Student Learning Styles

The majority of students in the study (65.8%) were sensing learners, with 39.5% having a moderate or strong preference to that learning style. However, 21.0% of students have a moderate or strong preference to intuitive learning over sensing learning. This suggests that there is a need for learning material for both types of learners, but the greater emphasis should be placed on reducing abstraction to better meet the requirements of the sensing learners, especially when it is seen that intuitive learners performed significantly better on the midterm examination.

In contrast, only 5.3% of students had more than a fair preference to a verbal learning style over visual learning. This suggests that there is less need for more verbal learning material than for more diagrams and visualizations. Results of the midterm examination, where verbal learners slightly outperformed visual learners, further support this idea.

In the processing dimension 73.7% of students have only a fair preference to either active or reflective learning, with the majority preferring reflective learning. Therefore, the learning material should be balanced to meet the requirements of both learning styles. This could be achieved by incorporating some interactive simulations and self-assessment questions with customized feedback as well as giving time for students to reflect on their learning experience.

Similarly, most students in the study are sequential learners, with 63.1% of students having only a fair preference to either sequential or global learning. Still, while not statistically significant, global learners performed slightly worse on the midterm exam than sequential learners. Thus it may be possible to improve the performance of global learners by offering more of a “big picture” view of the course. This could be achieved, for example, by comparing the concepts under study with other related concepts and applying them to different situations to show how the concepts interconnect.

Overall, the results indicate that increasing support for sensing and visual learners will have the greatest benefit for the course. Interactive animations provide one possible technique to achieve this. Such animations engage students visually and reduce the level of abstraction in the concepts under study (Naps, et al., 2003). Dynamic questions with immediate feedback allow students to monitor their understanding as they interact with the animation (Malmi, et al., 2004).

Student Self-Regulated Learning Strategies

Students' use of self-regulated learning strategies was moderate. Correlation analysis showed that metacognitive strategies were significantly correlated with elaboration, organizational and critical thinking strategies, indicating that students who use more metacognitive learning strategies are more likely to be aware of the cognitive strategies as well. However, metacognitive strategies were the least popular of the self-regulated learning strategies included in this study. This indicates that students may benefit from further education of possible self-regulated learning strategies which could be achieved by introducing interventions such as new educational software that encourages the use of different self-regulated learning techniques.

Conclusions and Future Work

This paper presented the results of an investigation into students' learning styles and their use of different self-regulated learning strategies in a core computer science course. The main aim of the study was to understand students' preferences and the self-regulated learning strategies they use. The results show a diversity of learning styles among students, with the majority showing a preference towards the visual and sensing learning styles. The influence of students' learning styles on their academic achievement in the course was also discussed, as were some recommendations to make the course more compatible with different learning styles. Intuitive learners, who represent only 34.2 % of the course cohort, significantly outperformed the 65.8 % of students who have a sensing learning style. This is consistent with the observation that most instructors use a teaching method that suits intuitive learners (Layman, Cornwell, & Williams, 2006), suggesting that the teaching strategies being used are not optimal for the majority of learners in the course.

The study included an analysis of the self-regulated learning strategies used by students, and it was discovered that metacognitive strategies, which were the least used by the students, were significantly correlated with many of the other strategies. The results of this study can be combined with the contemporary educational paradigms to provide a framework for improving the teaching of the next iteration of the "Programming Language and Paradigms" course as a pilot course representing computer science.

Based on this work, an online collaborative learning object repository is under development. This provides an environment for students to interact and share different learning objects to support traditional computer science teaching. The system contains a learning style assessment module to allow students to identify their preferred learning styles. Based on the result, students are provided with recommended strategies to follow throughout the course. The students' learning styles are also used by the system to automatically recommend learning objects that are most compatible with each individual student's preferences. New learning objects can be created inside the system through the use of a special template that helps ensure that aspects of different learning styles are taken into consideration.

As well as recommending the most compatible learning objects, the online collaborative system also aims to increase students' awareness of different self-regulated learning strategies. To help increase individual cognitive learning strategies, a collaborative filtering technique provides students the opportunity to rate and comment on existing learning objects. This allows the student to reflect on his or her learning experience, and the feedback enriches the repository for other users. Metacognitive strategies are also supported by the system, with the generation of self-assessment exercises allowing students to better monitor their knowledge of the concepts being studied.

While still in an early stage of development, the new online collaborative learning object repository will be fully operational by the end of the year. The system will be used in conjunction with the traditional teaching of "Programming Languages and Paradigms" in the first semester of 2012. Results of the 2012 course will then be compared to the results presented in this study to help evaluate the new teaching approach. It is hoped that the support offered by the new system will improve equality of teaching for computer science students, by offering the best strategies and objects for their different learning styles.

Despite the considerable potential for e-learning to help bring about improved learning outcomes, particularly for female students and students who need to rely on distance learning, feedback from current users of e-learning systems in the Kingdom of Saudi Arabia (KSA) suggests a relatively low level of satisfaction. This study adopts a mixed-methods approach to investigate the underlying reasons for this situation. The results indicate that students are not unhappy with the information technology infrastructure or with other technical aspects. However, many students report a low level of interaction between them and their fellow students. When such interactions do occur, an overwhelming majority of students indicate that they find such interactions. Together, these findings suggest that greater student interaction, which could be fostered through the use of collaborative learning, is likely to be both popular with students and beneficial to their learning outcomes.

Keywords: e-learning, collaborative learning, Saudi Arabia.

Introduction and background

According to the Communications and Information Technology Commission (CITC), the Kingdom of Saudi Arabia (KSA) is one of the fastest growing countries in the world in terms of e-learning. CITC data shows an explosive growth in the number of internet users generally, from a mere 200,000 in 2000 to 4.8 million in 2006 (CITC 2010). The number of students enrolled in institutions of higher education has also increased significantly in recent years. As a result, many of these institutions have turned to e-learning systems as a means to help broaden and enhance access to their courses and subjects (Al Saif 2005). Reflecting this trend, a growing number of research studies have been conducted on e-learning in KSA. Many of these studies have focused on identifying the key factors that differentiate online education from face-to-face learning, analysing the advantages and disadvantages of online courses, investigating factors that facilitate or hinder the adoption of e-learning, or developing strategies to achieve a suitable online learning environment (Alshehri 2005). To date, however, relatively little attention has been paid to the issue of assessing the e-learning environments that have been set up in the country, especially from the viewpoint of student users.

This paper is part of a research project that has been conducted in response to this gap in the literature. The overall project's aim is to evaluate existing e-learning environments in KSA on the basis of a range of criteria and dimensions (Alkhalaf, Nguyen & Drew 2010). A key purpose of the present paper is to focus more narrowly on student perceptions and feedback regarding these e-learning environments. It turns out that the level of satisfaction among student users is rather low. In the paper we also investigate some factors which may account for this disappointing result. Our findings suggest that one possible method to enhance existing e-learning environments may be to promote greater use of collaborative learning, which has the potential to make e-learning both more popular with the students and more effective in terms of learning outcomes.

Interest in e-learning has grown rapidly during the past decade or so in KSA, for at least several reasons (Albalawi 2007). First, the demand for higher education has far outstripped supply, such that institutions are faced with overcrowding and insufficient facilities and human resources for the delivery of traditional-style education to all of the nation's qualified applicants for admission. This has occurred despite the fact that in the five years to 2009, growth in the higher education system had seen the opening of one university every three months and five colleges every month, and the award of 800 scholarships every month to students going abroad for further studies (Al-Shehri 2010). According to Al-Khalifa (2010), "thousands of students are over-enrolled … and are simply given the course materials and sent home to study on their own." E-learning has been suggested as a means to overcome the continuing limitations.

Second, KSA is a large country in terms of geographical area, with a significant number of communities being isolated from major population centres. E-learning offers the potential to deliver educational services to remote locations, thereby reducing disparities across the various regions and areas. Third, in KSA's higher education, men and women receive their instruction in separate classes, for cultural and religious reasons (Mirza 2007, 2008). This puts further strains on the limited facilities and human resources available. In particular, there is a considerable shortage of female lecturers (Al-Khalifa 2010). It has been observed, accordingly, that women are often among the strongest supporters of e-learning, and may have the most to gain from further growth in e-learning (Bates 2009).

In 2008 the KSA Ministry of Higher Education established a National Centre of E-learning & Distance Learning to promote and facilitate the spread of e-learning systems in Saudi universities. For a description of how various e-learning environments have been set up throughout the country, in the universities as well as the technical education and vocational training sector, see Al-Khalifa (2010) and Al-Jarf (2007). The latter also provided an analysis of the challenges facing providers of these e-learning environments. In keeping with the rapid expansion in e-learning infrastructure and usage, the number of studies focusing on Saudi experiences with e-learning has also grown. According to a survey by Weber (2010), the total number of peer-reviewed studies of e-learning in KSA published during the period 2000-2010 was over 150, making the country the second highest producer of such studies in the Middle East and North Africa region.

Despite this voluminous literature, the number of studies that focused on assessments or feedback from students who have actually used the existing systems has been rather small. For example, Ali, *et al.* (2003) were more interested in factors which influence students' preferences for online courses vs. conventional classes than in the feedback from students who have taken online courses. Similarly, Alenezi, *et al.* (2010) focused mainly on the determinants of students' decision to accept or reject e-learning, rather than their experiences once they have decided to accept. In this paper, we contribute toward addressing this relative gap in the literature by studying the requirements, preferences, as well as experiences of students who have used e-learning systems in KSA.

Methods

The research underlying this paper involved a mixed-methods approach. Informed by the findings of previous studies of e-learning in KSA, a series of interviews were conducted to obtain qualitative information. Based on this information, as well as a review of related studies involving user satisfaction surveys, a questionnaire instrument was then designed and used to collect quantitative ratings.

Four faculty members from King Saud University and two from Qassim University were selected at random for the interviews. The only requirement was that they had conducted teaching with some use of e-learning technology. The questionnaire instrument consisted of 21 questions, which had been developed after a review of a large number of recent surveys of user perceptions and satisfaction in the ICT, IS and e-learning fields, including Mansour & Mupinga (2007), Gable, Sedera & Chan (2008), Wang, Tang & Tang (2001), Wang & Liao (2007) and Wang, Wang & Shee (2007). Questionnaire forms were distributed to 130 undergraduate students at the same two universities as above, again at random, with the only proviso that the recipient had taken a course which used e-learning technology. 88 sets of responses were returned, but only 77 sets contained usable responses.

Findings

Qualitative findings from interviews

The findings from the interviews were qualitative. Due to space limitations, they cannot be described in detail here. It is nevertheless important to acknowledge that they helped the authors to gain a better understanding of the e-learning situation in KSA, especially the use (or non-use) of collaborative-learning tools and methods, and students' general attitudes about e-learning. In turn, this knowledge facilitated the development of the questions to be included in the survey instrument.

Quantitative findings from questionnaire survey

Table 1 presents a numerical summary of the responses obtained from the 77 participants in the questionnaire survey. The answers to each question are coded according to a five-point Likert scale, where typically 1 indicates the least, and 5 the most, favourable rating from an e-learning point of view. The first 7 questions relate to the respondent's personal preferences, requirements and acceptance of e-learning as an alternative mode of learning. The average ratings on these questions are mostly between 3.0 (indicating a neutral stance) and 4.0 (indicating a favourable stance).

For example, in response to Question A1, the average rating is 3.47, suggesting that students were generally confident and comfortable with using the relevant technology required for e-learning. Similarly, the mean response to Question A2 is 3.53, indicating that students had a moderate amount of trust in the information that was presented through e-learning. The mean response to Question A3 is quite high (4.21), suggesting considerable enthusiasm for audio and video material, and pointing to an area where e-learning technology clearly has the potential to make a positive contribution. The mean rating for Question A4 is also favourable (3.94), confirming that students found it useful to be able to download and/or print learning materials for ready access.

Question A5 is of direct relevance to our purposes, as it asks participants to indicate the extent to which they would prefer if the lecturer used e-learning technology, including collaboration tool. Students' responses are rather lukewarm: the average rating is only 2.88, which is slightly less than neutral. In the context of answers provided to other questions as well as to this one, we interpret this rating as indicating that where students already had access to lecturers on a face-to-face basis, they did not have any strong desire for increased use of e-learning technology. This result is consistent with previous findings (e.g., Ali, *et al*. 2003).

By contrast, students provided highly affirmative responses when asked whether e-learning offers opportunity for women to attend online classes instead of mixed classes (Question A6), giving this question one of the highest mean ratings (4.58) in the survey. It is clear that, on the whole, respondents recognised the important role that e-learning can play in helping women to overcome possible obstacles to higher education. This is consistent with the suggestions from some previous authors that the biggest winners from greater use of e-learning in KSA are likely to be women (see references provided above).

It is interesting to compare the moderately favourable responses (mean = 3.57) to Question A7, which asks the extent to which students *accepted* the use of e-learning instead of face-to-face classes, with the rating of only 2.88 obtained for Question A5 (discussed above). Taken together, these responses suggest that although students with access to face-to-face classes did not particularly wish to see greater use of e-learning technology, they did recognise the essential role of e-learning in the current KSA context, e.g., to meet the requirements of a rapidly growing education system and to address the needs of female students as well as students in remote areas.

The next 5 questions are related to various aspects of the existing e-learning setup. Question B1 is the most general, asking students to provide an overall rating on the current use of e-learning in KSA. The answers are generally negative, yielding a mean rating of only 2.22, the lowest of all mean ratings in Table 1. (Recall that in this context, a rating of 2 would indicate an assessment of “poor“.) In view of the vast amounts of resources that have been invested in developing e-learning systems in the Kingdom over recent years, such negative assessments must be seen as disappointing. However, they are consistent with the suggestion made by some previous authors (e.g., Bates 2007) that e-learning in KSA is like the road system there: the infrastructure is already in place and is generally good, but usage of the infrastructure remains poor.

Table 1: Summary of responses to survey questions

Questions		Mean	SD
Personal preferences and acceptance of eLearning			
A1	How confident are you in the use of e-learning technology?	3.47	1.10
A2	How much do you trust the information which is presented through e-learning technology?	3.53	0.86
A3	To what extent does the quality of audio and video material help you to obtain a high level of e-learning?	4.21	0.92
A4	How important is it for you to be able to download and / or print e-learning materials?	3.94	1.08
A5	I would prefer if the lecturer used e-learning technology, including collaboration tools.	2.88	1.23
A6	Does e-learning offer opportunity for women to attend online classes instead of mixed classes?	4.58	0.89
A7	To what extent do you accept the use of e-learning instead of face-to-face classes?	3.57	0.93
Aspects of e-learning including technical issues			
B1	How do you rate the use of e-learning in Saudi Arabia's universities?	2.22	0.98
B2	How do you rate the response time of your e-learning system ('browser speed')?	3.36	1.08
B3	How would you rate the level of availability (ease of access) of e-learning during peak usage times?	3.36	1.77
B4	How would you rate the importance of the e-learning technology infrastructure (software and hardware) in this class?	4.22	1.02
B5	The information or functionality that you need is easy to find (system is easy to navigate).	2.61	0.97
Interaction and collaboration			

C1	Are you able to interact with the lecturer during class, using the available e-learning technology?	3.37	1.15
C2	How would you rate the level of interaction with your classmates or other students during use of the e-learning system?	2.82	0.98
C3	Does this course require that you collaborate with other students in the class (e.g. group project)?	3.21	1.97
C4	Do you feel the need to collaborate (discuss or informally interact) with other students in this class?	3.86	1.77
C5	How would you rate the usefulness of interaction with your classmates or other students during use of the e-learning system?	4.60	0.97
C6	How do you rate the ease of using collaborative e-learning in this course?	3.36	0.85
C7	Does the technology provide facilities for collaboration?	4.21	1.5
C8	If you are using the technology to interact with classmates (individuals or in groups) please rate the ease of use of this technology.	3.47	0.84
C9	The design of the collaboration tools (chatroom, discussion board, etc) is suitable for my needs.	3.87	0.98

Responses to Questions B2 to B5 generally support the above interpretation. The mean ratings for B2 and B3 (both 3.36) indicate that browser speed, system response time, etc. were not a problem for students, even during peak usage times. Responses to Question B4 (mean = 4.22) confirm that students saw both software and hardware infrastructure as highly important. This finding has implications for designers and advocates of e-learning systems, as does the fact that answers to Question B5 (about the ease of navigating e-learning systems) are generally negative (mean = 2.61). To the extent that dissatisfaction with current systems could be reduced via changes in information technology systems, it appears that the most useful of such changes are likely to be on the “soft”, rather than the “hard”, side.
The last 9 questions in Table 1 focus on the interaction and collaboration between users of the current e-learning systems. For brevity, we shall now discuss overall patterns in the responses to these questions, highlighting individual questions only where they are of special interest. In general, the ratings obtained for Questions C1 to C9 are quite positive, ranging mostly from 3.36 to 3.87. On the lower side, there are two exceptions to this general observation. Question C2 asks the respondent to rate the level of interaction with their classmates or other students during use of their e-learning system, whilst Question C3 asks if the relevant course requires students to collaborate with each other. The average responses (2.82 and 3.21, respectively) are close to neutral, but they mask the fact that the distributions of the relevant ratings are bi-modal: a sizable group of the respondents had not been required to collaborate (C3), and therefore it is not surprising that their ratings for Question C2 are lower than ratings from students who had been required to do so. As we shall see below, how these bi-modal distributions relate to each other may hold significant implications for academics as well as designers of e-learning systems.

On the upper side, a clear exception is Question C5, which is about students’ assessment of the usefulness of interaction with their fellow students. The mean rating for this question (4.60) is the highest of all questions included in the survey. This overwhelmingly positive response suggests that a relatively efficacious (“low-hanging fruit”) approach to improving students’ satisfaction would be to facilitate and encourage greater interaction and collaboration among themselves. It has long been accepted that a collaborative approach to learning offers many distinct advantages (see below). The current results suggest that those advantages apply strongly in the case of e-learning in KSA at the present time.

If universities were to decide to make a shift toward collaborative learning, it would be highly feasible to carry out this shift from an infrastructure point of view: at 4.21, the mean rating for Question C7 is higher than most, indicating that the existing technology already provided adequate facilities for student interaction and collaboration. This result is consistent with the average rating for Question C9, which indicates a favourable

(3.87) assessment of the current design of collaboration tools, such as chat rooms, discussion boards, etc.

Differences in responses by male and female students

It is evident from the above discussion that in KSA female students have requirements and expectations regarding e-learning that may be quite different from those of male students. Accordingly, Table 2 compares and contrasts the responses from male and female participants. The last two columns present summary results from applying the non-parametric Mann-Whitney test to corresponding ratings from these two groups.

It turns out that the answers from women differ significantly (at the 10% significance level) from men's responses to only three questions. In response to Question A1 and C6, the ratings from women are systematically lower than from men, indicating that female students tend to feel less confident and comfortable with using e-learning technology in general and with collaboration-enabling technology in particular. Nevertheless, they are more receptive than men to the possibility of greater use of e-learning technology by current lecturers (Question A5). Taken together, these results suggest that although women might be less likely to perceive themselves as proficient with the technologies involved, they tend to see greater net benefits arising from a hypothetical increase in the use by faculty members of e-learning technology.

Differences in responses by students who were required, and students who were not required, to collaborate

Table 3 presents a comparison between ratings from students who were not required by their e-learning course to collaborate with fellow students and ratings from students who were required to do so. Mann-Whitney test results indicate that the ratings from the latter group are significantly higher than ratings from the former with regard to a number of questions. Of these, Questions C4 and C2 are probably the least surprising inclusions: in courses where students were required to collaborate, one would indeed expect that they felt a greater need to do so (overlapping perhaps with a sense of compulsion), and that they ended up collaborating more than if there had been no such requirement.

Table 2: Differences in responses by male and female students

Questions (abbreviated)		Males		Females		Mann-Whitney	
		N1	Mean	N2	Mean	Z	Prob.
A1	Confident in the use of e-learning technology?	51	3.61	17	3.06	-1.89	0.06
A2	Trust information presented through e-learning?	48	3.50	14	3.64	-0.46	0.64
A3	Quality of audio and video material help you?	56	4.27	16	4.00	-1.07	0.28
A4	Important to download & print materials?	48	3.94	14	3.93	-0.48	0.63
A5	Prefer if lecturer used e-learning technology.	45	2.73	12	3.42	-1.69	0.09
A6	e-Learning offers opportunity for women to attend?	45	4.71	15	4.20	-1.61	0.11
A7	Do you accept e-learning instead of face-to-face?	53	3.58	16	3.50	-0.20	0.84
B1	How do you rate the use of e-learning in Saudi Arabia's universities?	48	2.21	12	2.25	-0.25	0.80
B2	Rate response time ('browser speed')?	48	3.35	13	3.38	-0.24	0.81
B3	Rate availability during peak usage times?	36	3.33	9	3.44	-0.18	0.85
B4	Rate importance of technology infrastructure (software and hardware)?	44	4.27	10	4.00	-0.93	0.35
B5	System is easy to navigate?	53	2.55	16	2.81	-1.37	0.17
C1	Able to interact with lecturer during class, using the available e-learning technology?	49	3.39	16	3.31	-0.41	0.68

C2	Rate level of interaction with classmates or other students during use of the e-learning system?	51	2.75	14	3.07	-1.06	0.29
C3	Rate usefulness of interaction with classmates or other students during use of system?	39	4.56	11	4.73	-0.11	0.92
C4	Does this course require that you collaborate with other students in the class (e.g. group project)?	50	3.06	16	3.69	-0.98	0.33
C5	Do you feel the need to collaborate with other students?	54	3.70	17	4.35	-1.11	0.27
C6	Rate the ease of using collaborative e-learning?	43	3.49	16	3.00	-1.93	0.05
C7	Does the technology provide facilities for collaboration?	46	4.13	11	1.45	-0.64	0.52
C8	If you are using the technology to interact with classmates please rate ease of use of this technology	48	3.50	14	3.36	-0.54	0.59
C9	Design of collaboration tools (chatroom, discussion board, etc) is suitable for my needs	47	3.81	13	4.08	-0.71	0.48

Of greater interest is that ratings for Question A5 from the latter group (required to collaborate) are significantly higher than those from the former, suggesting that as students were required to collaborate with each other, such interaction tended to spill over to greater acceptance of usage by the *lecturers* of e-learning technology. It is also interesting to note that students who were required to collaborate gave significantly lower ratings for Question A4, suggesting that they might find information sharing and peer-group discussion to be more useful than strict adherence to class material, which tended to be far more important to students who studied by themselves.

Two other results reported in Table 3 are also of considerable interest, despite being not statistically significant (at the 10% level). First, responses to Question B1 suggest that students who were required to collaborate in their e-learning course might have a rather more favourable view of e-learning overall: their average rating is 2.41 compared with 2.14 for the group not required to collaborate -- the difference would have been significant at the 30% level. Second, 14 of the students who were not required to collaborate *did so anyway*: as their mean rating for Question C3 (4.93) shows, these 14 students were nearly unanimous in reporting that the experience was very useful to them (recall that 5 is the highest possible rating).

Table 3: Impact of requirement to collaborate

Questions (abbreviated)		**Not required to collaborate**		**Required to collaborate**		**Mann-Whitney**	
		N1	**Mean**	**N2**	**Mean**	**Z**	**Prob**
A1	Confident in the use of e-learning technology?	24	3.79	32	3.16	-2.04	0.04
A2	Trust information presented through e-learning?	20	3.55	31	3.52	-0.05	0.96
A3	Quality of audio and video material help you?	27	4.41	32	4.03	-1.58	0.11
A4	Important to download & print materials?	22	4.23	30	3.73	-1.88	0.06
A5	Prefer if lecturer used e-learning technology.	20	2.50	30	3.13	-1.97	0.05
A6	e-Learning offers opportunity for women to attend?	20	4.60	30	4.57	-0.58	0.56
A7	Do you accept e-learning instead of face-to-face?	26	3.65	32	3.44	-0.65	0.52
B1	How do you rate the use of e-learning in Saudi Arabia's universities?	22	2.14	29	2.41	-1.04	0.30
B2	Rate response time ('browser speed')?	23	3.48	29	3.14	-0.94	0.35
B3	Rate availability during peak usage times?	13	3.77	25	2.96	-1.35	0.18

Implications: potential role of collaborative learning

A natural implication of the above findings would seem to be that e-learning courses in KSA should encourage, or indeed should even require, students to collaborate. Thus the collaborative (or cooperative) learning approach may be able to play an important role in enhancing the effectiveness of current e-learning environments. This learning approach has long been the subject of much study by educational researchers and designers (e.g., Slavin 1980, 1983a, 1983b, Hooper 1992, Koschmann 1996, Okamoto 2003, Tomsic & Suthers 2006, Dewiyanti, *et al.* 2007, Liaw & Huang 2007, Cattafi & Metzner 2007).

Collaborative e-learning offers many advantages. The process itself tends to increase interaction and create a sense of belonging. Collaborative e-learning environments may allow students, especially those who are shy in face-to-face situations, to participate in online discussions and meetings, offer and receive critiques, negotiate, and build consensus. This advantage may be of special significance in KSA, where face-to-face interactions between male and female learners are often not an option.

Of course, conflict between individuals can also occur, and a poorly designed or poorly run e-learning environment may allow some negative, undesirable interactions to develop. Therefore, care must be taken in developing and moderating the relevant environment.

In the current context, where many Saudi universities have already put in place their own e-learning environments, the process of increasing the emphasis on collaborative learning can be implemented through a series of coordinated, institution-wide measures, as illustrated in Figure 1. As envisaged, there would be a project (upper left hand side of Figure 1) aimed at coordinating efforts to enhance the existing e-learning environment, and possibly another project (lower left hand side) aimed at enhancing the learning management system (LMS) if this is required.

The e-learning improvement project's key activities would be:

1. to redefine/amend principles, policies and tasks associated with the current e-learning environment in order to re-orient it more toward collaborative learning;
2. to provide training and technical support to faculty staff as they revise their teaching materials and methods; and
3. to redefine/amend principles, policies and tasks of the LMS.

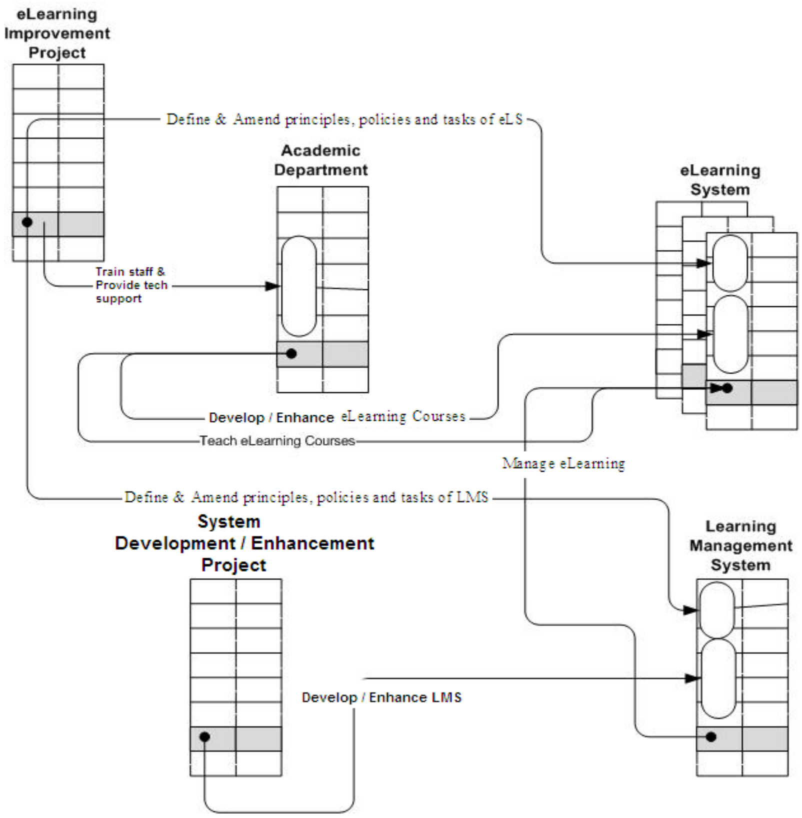

Figure 1: Proposed measures to enhance existing e-learning environments

Conclusion

Responses from students at two major Saudi Arabian universities suggest that existing e-learning systems in the country are rated rather unfavorably by student users. This has occurred despite massive investments having been made in terms of infrastructure, hardware and software, and despite the fact that students are generally satisfied with technical issues, such as browser speeds and system availability during peak usage times. There are reasons to believe that student satisfaction levels may be increased if they are encouraged (or indeed required) to interact more with their classmates and colleagues while using e-learning systems.

At present student dissatisfaction does not stem from a lack of available technology: indeed, students are satisfied with the design of available collaboration tools (e.g. chatrooms and discussion boards). However, it appears that course designs have not made sufficient use of such collaboration tools. Almost half of the responding students report that they are not required to collaborate with other students. Students who are required to collaborate (e.g. group projects) tend to report more positive responses to e-learning experiences. Efforts to encourage student interaction, even to the extent of requiring students to complete compulsory collaborative tasks, are thus likely to enhance Saudi Arabian students' e-learning experiences.

The creative graduate: cultivating and assessing creativity with eportfolios

Belinda Allen
The University of New South Wales

Kathryn Coleman
The University of New South Wales

Changing demands for graduate capabilities lead to changing directions for undergraduate assessment. 'Creativity' is a widely promoted graduate capability that relates to many others, such as independent learning and innovative problem-solving. Assessment practices need to become more focused on the evaluation of generic capabilities, additional to assessment of discipline-specific knowledge. This has implications for the content, design and modes of assessment. Assessment as learning promotes an approach in which the learning activity and assessment task are one and the same, and authentic assessment design incorporating group work, problem-based, online and portfolio assessment enable the development of generic capabilities to be embedded in the discipline. The paper explores creativity as a graduate capability, the creative potential of digital media, and how changing directions in assessment practice could support the assessment of creativity, with a focus on using eportfolios in assessment.

Keywords: creativity, assessment, eportfolios, graduate capabilities, digital literacy

The creative graduate

Creativity is increasingly represented in higher education aspiration statements as an attribute that graduates require to successfully engage in contemporary and future professional life. Several other generic capabilities seem intrinsic to creative behavior such as independent learning, critical thinking, innovative problem solving and information and digital literacy, but how are these to be embedded into curriculum and assessment practice? Portfolios have been widely used in 'creative' disciplines in higher education, and are beginning to be more prevalent in disciplines where evidence of meeting professional standards across a range of capabilities is critical. The emergence of technologies to support eportfolios allows not only the aggregating of material in a wide range of formats, but also the embedding of peer review and selective sharing via social networks. Eportfolios have the potential to provide a platform for holistic development and assessment of a range of graduate capabilities related to creativity.

The importance of creativity as a graduate attribute

The cultivation of creativity, not as an arts-related addendum to school curricula, but as an educational approach in itself has been seized upon by educationalists and cultural commentators such as Robinson (2000), Florida

(2002) and Pink (2005) who maintain that apart from any individual humanist benefit, new millennium economic imperatives demand the development of a greater capacity for creativity, among other dispositions such as empathy and collegiality. Robinson (2010) makes a compelling argument for the dismantling of educational paradigms that were developed to suit an industrial age economy, and a great deal of effort has been expended in the UK in particular in renewing curriculum to accommodate a more creative approach. Higher education too has been paying attention to the development of 'creative' graduate attributes such as innovative problem-solving, creative leadership and interdisciplinary practice.

Some transformative learning theorists suggest that a radical critique of the form and function of education is required, which must urgently engender new visions to deal with complex global problems (Miles, 2002; O'Sullivan, 1999; 2003; O'Sullivan & Morrell, 2002). This recalls Barnett's “being-for-uncertainty”, a quality that graduates need to develop to manage the 'supercomplexity' that is characteristic of the contemporary world, which is characterised by “certain kinds of disposition. Among such dispositions are carefulness, thoughtfulness, humility, criticality, receptiveness, resilience, courage and stillness.” (Barnett, 2004, p.258).

Industry agrees with these views, asserting that university graduates need a range of generic capabilities. A 2010 global study of CEOs by IBM found that creativity was believed to be the most crucial factor for a company's future success (IBM, 2010), and the Business Council of Australia (2006) identified the importance of creativity among other related capabilities, and cited employer concerns that graduate skills are lacking in these areas. Amabile (1998) has long suggested that industry would benefit by providing opportunities for employees to exercise their creativity, and suggests that the qualities required for creativity in business are expertise, creative thinking skills and motivation.

What does it look like?

Creativity is now increasingly promoted as a desirable learning outcome in different disciplines, and more generically as a graduate capability in higher education, so how can it be characterised in this context?

Conceptions of creativity as differentiated between ‘high’ (large-C) and ‘ordinary’ or ‘democratic’ (small-c” have emerged in recent decades, to support the idea that creativity is not the domain of only the brilliant and eminent, but is achievable by everyone (Csikszentmihalyi, 1996; Craft, 2001). These ideas have more recently been characterised as second-generation (McWilliam & Dawson, 2008), emphasising the social/cultural context and universal and collaborative nature of creativity in contrast to more traditional, first-generation, conceptions of creativity as mysterious, individual, and dependent on inspiration and aptitude The second-generation focus emphasises a personal, practical and socially-oriented creativity, and “locates the creative enterprise in the processes and products of collaborative and purposeful activity” (McWilliam & Dawson, 2008, p.633). While popular conceptions may continue to reflect first-generation notions it is the second-generation focus on creative capacity building that provides a more useful platform in the educational context (McWilliam & Dawson, 2009), and is a better fit with the professionally-oriented attributes articulated in higher education aspiration statements and industry skill-set statements.

Recent research suggests that creativity is best characterised as behaviour in a context, rather than as a skill or a capability, demonstrated by output or product, and that it may be more appropriately defined as a disposition (Ivcevic, 2009). Behaviour characterising a creative disposition encompasses a range of abilities and attitudes, including taking risks, making connections between disparate fields of knowledge, and being a motivated and independent learner. Such attributes could themselves be considered in the realm of dispositions rather than quantifiable skills or capabilities, incorporating the affective as well as the cognitive dimension of learning. For instance, some of the cognitive characteristics of creative behaviour that have been identified by Tardif and Sternberg (Sternberg, 1988) in their review of creativity research are: articulate and fluent, good imagination, flexible and skilled decision-maker, copes well with novelty, and finds order in chaos.

Creativity in curriculum

Academic and student conceptions

Investigating both academic and student attitudes to creativity in higher education, Jackson et al (2006) came across a range of understandings and definitions that were complex and frequently contradictory. Some students and teachers maintain a lingering attachment to romantic and individualist aspects of creativity, and are sceptical that it can be taught. Australian research has also shown that academic teachers often have understandings about creativity that combine first- and second-generation conceptions (McWilliam and Dawson, 2009). However, both academics and students believe that creative teaching can enable students to be creative in learning activities and outcomes. Students identified dialogic modes, where students' current understandings or beliefs are addressed, as supportive of creativity, while they felt strongly that prevailing modes of assessment (such as examinations) were generally inhibitive for creativity. Students also expressed frustration at a perceived conflict between being creative and conforming to 'academic' expectations (Oliver et al, 2006).

Academic conceptions across disciplines represented generic features of creativity such as: originality, use of imagination, exploration and risk-taking, making sense of complexity, and story-telling, and many academics believed that development of creativity was important, even though creativity was rarely explicit in learning outcomes or assessment criteria (Jackson & Shaw, 2006).

Creative teaching/creative learning

To accommodate these features of creativity in curriculum requires the setting of appropriate tasks in an appropriately flexible environment to both promote and support creative responses, and to allow risk-taking and mistake-making in a safe environment. Studies of school teachers have reported that while teachers apparently believe that most of their students have the potential for creativity, those students who display creative behavioural characteristics (such as playfulness, argumentativeness, independence) tend to be perceived by teachers as non-conformist and disruptive (Craft, 2001; Aljughaiman & Mowrer-Reynolds, 2005). It is not surprising then that students arrive in tertiary education with these behaviours repressed, and creative learning is unlikely to occur without a context in which creative behaviour is not only acceptable but supported and rewarded.

Sternberg (1996) has suggested that creativity is best taught through the teacher as a role model for creative practice. This is supported by Jackson et al (2006), who found that both academics and students believe that there is a close correspondence between creative teaching and the opportunity for creative learning. Teachers therefore need opportunities for innovating their own practice in a safe environment to enhance their self-perception as creative practitioners.

Assessment of creativity, even in creative disciplines, has tended to focus on assessment of product, whereas aspects of creativity such as process, person and place are all deemed to be critical to creative development (De la Harpe et al, 2009). The Studio Teaching Project (ALTC) has identified a range of identifiers in these different dimensions for the assessment of creativity, and has developed a holistic assessment model to support this.. The foci of this model are:

- Outcome dimensions: Product, process and person
- Knowledge and skills: underpinning and core
- Reflective and professional practice – acting like a [creative practitioner]

This model, represented in Figure 1, could be adapted to be more widely applicable across disciplines.

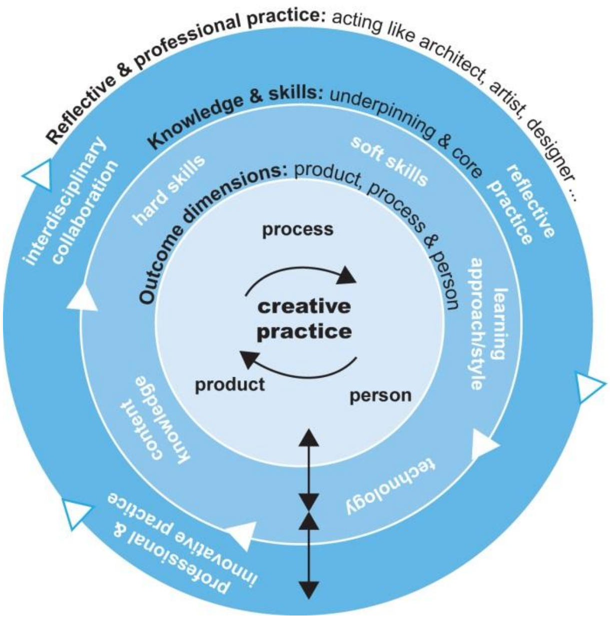

Figure 1. Model for holistic assessment in studio-based disciplines (adapted from De la Harpe et al, 2009, p47)

Assessing creativity with portfolios

The reflective aspects of this model are essential to provide the evidence for the ‘process’ and ‘person’ outcome dimensions, and the portfolio is an ideal assessment mode for these broader dimensions. Portfolios support the aggregation of selected pieces of evidence to demonstrate learning outcomes and achievements. To leverage the learning benefits of portfolio assessment, this usually includes a reflective dimension, where the learner analyses and evaluates their own learning processes.

Portfolios have the potential to support the development, demonstration and valid assessment of a wide range of personal, professional and academic capabilities, both inside and outside the study program, and develop good professional practice in the documentation and presentation of activities and artefacts. By allowing a degree of control over learning pathways and strategies, portfolio assessment promotes learner self-direction and motivation, and therefore engagement in learning activities. Because of the ability to aggregate different types of output, portfolios have been widely used in ‘creative’ disciplines, but are applicable to any discipline where the learning outcomes may require a range of types of evidence to be presented (Baume, 2001).

As Krause (2006) indicated “portfolios are a useful vehicle for facilitating critical reflection on one’s learning and for compiling and demonstrating evidence of learning and skill development” (p.1) as they catch and preserve the evidence of learning. This critical reflection is imperative for higher education in supporting the development of graduate attributes. Provision of evidence of these capabilities often is driven by the student toward the end of the learning cycle as students gather evidence for resumes or CVs for accreditation to associations and professional institutions.

This reflection on learning is important for students as they exit higher education and seek employment in their respective disciplines. Reflective practice and self-assessment of learning is critical for remembering, conceptualising and analysing constructed knowledge after time. As Strampel and Oliver (2007) inferred, “reflection is a way of thinking; it is a form of contemplation that determines how one comes to act on new understandings” (p.980). Portfolios are useful tools for this conceptualising of practice in assessment. They encourage and facilitate student reflection while they compile and develop evidence of learning throughout the learning process and at the completion. Utilizing digital platforms for this reflection can further enhance the learning process, including ongoing thinking and reflection and action on reflection (Schön, 1987).

Creativity and digital media

Digital literacy

Digital literacy is another capability emerging as a critical skill for graduates to function as global professionals in many fields. Prensky’s (2001) notion that ‘digital native’ students are well-versed in technology use in contrast to their ‘digital immigrant’ teachers has largely been discredited by subsequent research (Kennedy et al, 2008), who found that students are not homogeneous in their use of technology, which tends to be ad hoc and opportunistic. Students need support from their learning environment to not only learn how to use online learning systems, but also to identify, set up and evaluate a range of tools and networks and thereby apply digital production and networking skills to their study and work. While teachers may integrate and manage course elements in a learning management system (LMS), and that has great benefits for learners, practice for students in using a range of media, publishing and networking tools is likely to be more relevant to their professional lives.

Digital literacy inevitably overlaps with information literacy as students have available to them a morass of online information of varying quality and validity, and need to develop the skills to navigate, evaluate, select and contribute to online information. Matthew Allen (2009) refers to ‘knowledge networking’ as a new paradigm in professional and scholarly practice, and has developed strategies and identified available web applications to support teachers and students in higher education to develop the digital literacies required (Allen, 2011).

Technology can provide a platform for teachers to model and scaffold creative activities and outputs. Individual teachers may not be able to develop expertise in all the available technologies, but they need to be able to demonstrate a facility with an open and collaborative way of working, including the ability to learn on one’s feet when confronted with unfamiliar technology. This is an area where students and teachers could profitably learn from each other.

Creative digital tools

Digital media provide a plethora of opportunities for the design, development and presentation of creative work – the tools for creative production have arguably never been so accessible, with almost every student in Australian universities having access to a digital still or video camera, a desktop and/or laptop computer with image, audio and video editing capability, and high-speed internet access to a huge range of productivity software and publication platforms. The social orientation of Web 2.0 tools is highly supportive of the development of communication and networking skills. These are powerful resources for teachers and learners in the development of the broad range of capabilities intrinsic to creativity. What is required is the scaffolding for learners to produce, critique and publish work relevant to their field of study, in a way that will leverage this potential.

If key characteristics of creative behaviour are being able to take risks, step outside of one's comfort zone, and to think both divergently and convergently around different domains of knowledge, this is a meta-capability beyond the scope of any particular communication or publication tool. From this perspective, the design and scaffolding of the learning activity is of primary importance, and is where the creativity of the teacher has the most impact.

In the E-Learning and Social Networking Handbook, Mason and Rennie (2008) map a list of student learning needs and examples of related learning activity to a range of emerging technologies. The list does not specify that any of these learning needs or activities are related to learning creativity, or learning creatively. Yet it is not difficult to envisage how they may be employed to that end - the critical element is the creative focus being present in the intention of the teacher, the understanding of the learner, the design of the learning activity and the assessment of the learning outcomes. For example, see Table 1.

Table 1. (from Mason & Rennie, 2008, p.49)

Student learning need	Example of student activity	Extended/emerging technology
Developing understanding	Linking information from different sources	e-portfolios, Mashups
Linking theory to practice	Learning by doing	IMS tutorials, Screencasting
Practising articulation of ideas	Reflective journal	Blogs, Podcasts
Practising teamwork	Group projects	Social bookmarking, Wikis

Some of the Web 2.0 tools discussed by Mason and Rennie are: blogs, wikis, podcasts, e-portfolios, social networking, social bookmarking, photo sharing, Second Life, online forums, video messaging, e-books, instant messaging, Skype, games, mashups, mobile learning, RSS feeds and YouTube. Many others are available at: http://www.go2web20.net/.

Assessing with eportfolios

> "[Eportfolios] have the potential for transforming … curricula through the linking of practice-oriented learning and the development of graduate attributes" (Housego & Parker, 2009, p.409)

One of the benefits of a portfolio mode of assessment is that it scaffolds the compilation of evidence and artefacts in a range of media, which is then compiled into a presentation format, or formats, for a variety of purposes. An eportfolio approach provides additional affordances, in that it not only aggregates artefacts produced in digital form using technologies such as those listed above, but that it is integrated into online networking and communication tools to allow a wide range of connectivity and presentation options. The dimensions of practice, learning and research that can be aggregated and organised, and the range of purposes for which an eportfolio can be used is illustrated in Figure 2.

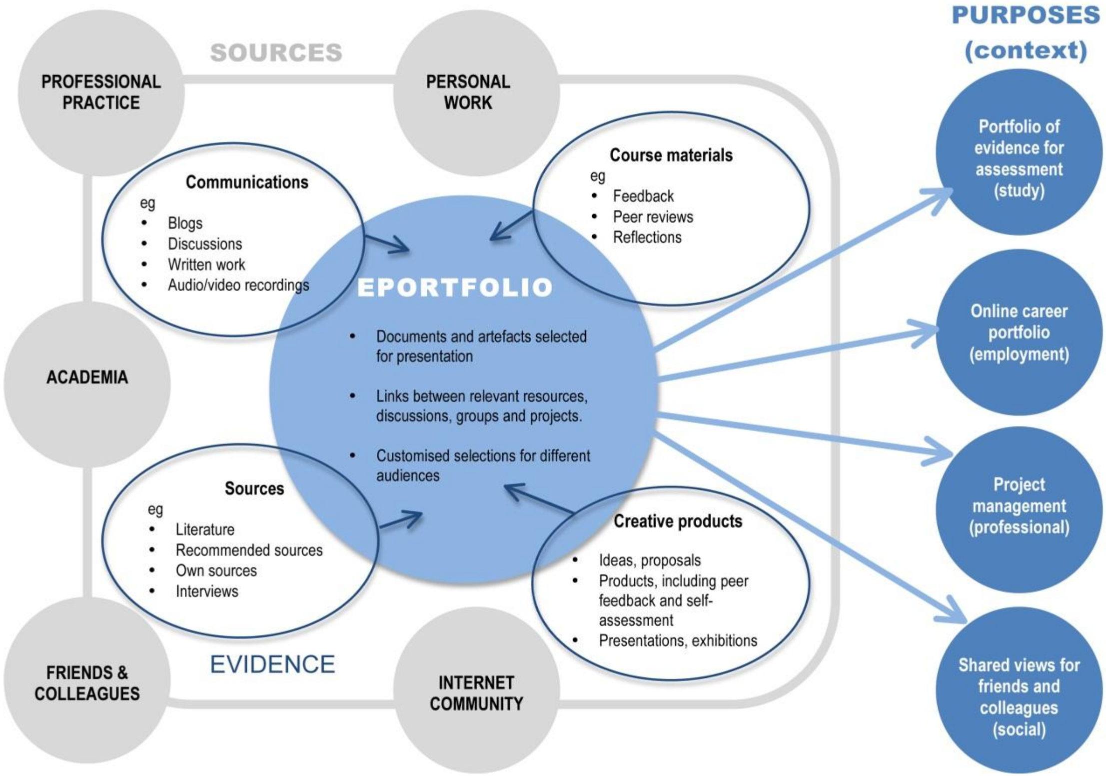

Figure 2. Model for eportfolio practice

As a pedagogical tool, eportfolios differ from more traditional folios of practice. In the 21st century, as Web 2.0 tools develop, eportfolios have the potential to address the lack of integration across existing programs because they can be used across teaching programs and contain all electronic documents related to learning from assessment tasks, tests, feedback and student work samples. As eportfolios are goal driven, students are self-directed and ownership of the portfolio helps students take responsibility for their own learning, and for publishing and disseminating their own content. For an example of how this could work to integrate student learning with professional practice, see the Scenario below.

Scenario

Alice Lee is an environmental engineering student, in her second year. The curriculum for her program includes many authentic activities and assessments to ensure that she develops broad professional skills alongside her discipline-based knowledge. With the new eportfolio assessment mode, it is her responsibility to see what skills she needs to develop and what assessment tasks she can complete to achieve the required outcomes.

Looking at her assessments so far, she has been doing well in evaluations of her achievements in creative problem-solving and self-directed learning. To demonstrate these capabilities she proposed an innovative solution for minimising pollution from fish-farming, and independently conducted a research project on the feasibility of her proposal. She now needs to do some team-work to gather evidence on her ability to lead and work within a team. A group project will also allow her to get peer feedback on her oral and written communication, and to demonstrate her ability to give and receive feedback.

Alice knows that her creative approach to projects is one of her strengths, but that it can be challenging to other team members. She selects a problem-based team project where her creative abilities will shine, and she hopes that through her leadership she will be able to help other team members develop their own creative abilities – being able to see problems from multiple perspectives, make connections between fields of knowledge, and take risks in proposing and testing possible solutions.

The curriculum materials include a project work template that is helpful in suggesting ways that the group can work to maximise creativity in their outcomes, as well as practice several other generic skills. The first strategy is for members to use a role-play activity to critique their own perspectives, and to develop some shared understandings of the problem, as well as awareness of the range of possible perspectives. One of the group members suggests that they use a social media network as they work on this – it allows them to easily publish their own thoughts, comment on others, and introduce any internet and other sources that they find. They will also be able to extract content from here to publish in the final eportfolio presentation. Alice finds this challenging as she has tended to be a solo worker, but knows that it will give her the opportunity to develop important digital literacy skills.

The team decides that their final presentation will be a website, which will allow them to aggregate a variety of media to show their project outcomes, and then easily publish to the internet for future use such as employment portfolios …

… It is four years later, and Alice is now employed at a regional council as environmental engineer. The course work she completed on her own as well as the group projects have been valuable in securing her career as through the eportfolio she was able to easily select and present the relevant work, and show evidence of the broad range of skills she developed. She's really happy, now that she's working away from the city, that she also learned so much about online networking and communication, and regularly runs workshops for other council employees on using digital tools.

The transformative potential of eportfolios

Transformation suggests a significant perspective change, which could apply personally to the learner and the teacher, as well as to the curriculum design and the teaching situation.

Intrinsic to transformative learning is the learner's experience of a disorienting dilemma which propels them into a cycle of critical reflection and dialogue, provoking them to question assumptions and 'try on' new perspectives (Mezirow, 1991). There are several aspects of eportfolio use that learners may find confronting or disorienting, including the development of efficacy with the relevant technologies, the incorporation of self- and peer-assessment into the learning process, and a more-or-less public enactment of the reflective cycle. For the transformative potential of eportfolio assessment to be realised this process must be scaffolded and supported – the simple provision of the technology is not sufficient. Effective assessment through eportfolios encourages critical reflection as students gather digital artefacts and evidence to demonstrate the development of their knowledge, skills and competencies. Eportfolios can further this gathering approach for folios by acting as an official record of a student's work. As (Housego & Parker, 2009) inferred, eportfolios "enable students to integrate their experiences at the University and make a substantial contribution to their personal development" (p.409).

The engagement of teachers in the practices and technologies of eportfolio use is important if they are to model creative practice, and this may be as confronting and transformative for teachers as it is for learners. Teachers are likely to be already engaged to some degree in development of their own portfolio of work, research and personal activities, and that this could be the basis for the development of their own eportfolio practice. This academic development process likewise needs to be supported and scaffolded, ideally through a community of practice where they are able to participate in critical reflection and dialogue with peers.

Hughes (2008) has asserted that eportfolios could be characterised as transformative technology in that using these in assessment requires a change to traditional assessment practices, and to learner and teacher roles in assessment: "Adopting eportfolios as genre and practice requires us to engage with our learners in meaningful individual and collaborative activities, it requires us to cultivate dialogic cultures which make connections beyond the immediate and it demands that we interrogate notions of authorship and audience" (p.439). Such questions of identity, communication and expression are intrinsic to conceptions of creativity as socially-mediated behaviour. Eportfolio assessment is able to focus on both cultivating and providing evidence of creative identity and voice, by scaffolding process and supporting evaluation across developmental dimensions (see Figure 2).

Krause (2005) indicated that while eportfolios have the potential to transform pedagogy; this potential cannot be realised without real curriculum change. Leveraging the use of technology for curriculum transformation is a complex process, explored by the JISC project 'Transforming curriculum delivery through technology: Stories of challenge, benefit and change' (2011). One critical finding of this study, which involved 16 institutions, was the importance of involving learners themselves in curriculum change:

> "The empowerment of learners through technology-enabled innovations is arguably the most far-reaching outcome from the programme. Work by the projects both enhanced learning and placed learners at the heart of curriculum change. Tools and processes to help learners make sense of the curriculum and adopt increasingly more active roles in its development and delivery"
> (JISC, 2011, p.9)

Key points relating to this were that "small but crucial interventions can result in transformative effects" and "greater learner empowerment requires an increased focus on digital literacy skills". (JISC, ibid, p.9)

Their 'Achieving transformation' graphic, representing some of the findings of this project, can be found at: http://www.jisc.ac.uk/media/documents/programmes/curriculumdelivery/Achieving_Transformation_figure.pdf

Eportfolios and graduate capabilities

Many characteristics intrinsic to creative behaviour are reflected in graduate capabilities that could be evidenced by eportfolio For instance the University of New South Wales (UNSW) Graduate Capabilities statement aspires to graduates as scholars who are: "understanding of the discipline in its interdisciplinary context, rigorous in their analysis, critique and reflection, digitally literate, able to apply their knowledge and skills to solving problems, are information literate and capable of independent and collaborative enquiry" (UNSW). This globally-focused UNSW graduate should be a leader in their field who demonstrates a life-long learning approach to professionalism and demonstrates creativity and innovation. These capabilities lend themselves to the objectives of an eportfolio, where students collect evidence in an authentic context, generating artefacts that demonstrate their problem solving skills and constructed learning through reflection, critique and analysis.

Designing eportfolio assessment

As educative spaces, eportfolios enable both a self-directed and an individualised approach to learning that can promote life-long capabilities in a program of study. As students develop the appropriate skills to self regulate their learning and become responsible for their learning beyond the walls of the classroom, they can engage both individually and collaboratively in the eportfolio. For educators seeking to develop personalised learning spaces or environments in their assessment, eportfolios have enabled this transition and opportunity. Hughes (2008) suggested the four cognitive skills required for self directed students in an eportfolio are 'collect, select, reflect, connect'. To support these skills to develop and be reflective in students' assessment, Krause's (2006) eight initiatives for successful integration of an eportfolio assessment in a program include:

4. Start small; plan the implementation slowly and clearly by integrating the concept of a portfolio into the course with some electronic components.
5. Build a program led approach to support and build a new culture in assessment, this takes time. Eportfolios have the potential to transform pedagogy; they cannot be implemented without real curriculum change.
6. Develop a strong resources plan for technical rollout, if possible participate in a pilot project and spend time developing technical proficiency among the team.
7. Collaborate with staff among the program and course structure, implementing a whole course rather an individual place the concept to the portfolio in a stronger position in the students mindset.
8. Align the learning outcomes to the eportfolio, defining the purpose of the portfolio with students and staff clearly.
9. Make the eportfolio a sustainable assessment tool rather than another add-on, ePortfolios can be used to track and gather resources f students from year 1 onwards.
10. Establish clear professional development and skill based workshops and support through initial face-to-face meeting.
11. Prepare the evaluation to support enhancement, exclusion and improvements early and throughout the course

and use of the eportfolio.

As these initiatives preface, time is imperative in the successful integration of this form of assessment. Like other forms of transformational technologies, they cannot be 'added-on'. Time to establish an eportfolio for assessment in a course or program is needed to learn the appropriate skills needed for both student and staff implementation, the required technical proficiency for both staff and students and the ability to critically reflect and select work for assessment. One of the challenges of this assessment practice is the time to 'reflect, collect, write, and respond to their feedback'. Eportfolios have the potential to provide ways for students to use feedback from assessment and utilise it to support their future learning.

Further development in assessment of creativity with eportfolios

This paper has briefly explored how changing directions in assessment practice could support the assessment of creativity, with a focus on using eportfolios for assessment. A study is being done with UNSW academics who are currently using eportfolios for assessment, to investigate how they are being used and perceptions of the effectiveness of this approach. A wider research project is in development to explore how technologies can support the development and assessment of creativity, and will report on academic and student perceptions and experience in a range of disciplines. This will build on findings from several recent projects that have explored case studies and developed support materials in the areas of both teaching in creative disciplines and online teaching and assessment. Australian projects include ALTC supported projects: Australian ePortfolio Project (2009), Studio Teaching Project (2009), Assessing Creativity: Strategies and Tools to Support Teaching and Learning in Architecture and Design (due 2011) and Matthew Allen's Learning in Networks of Knowledge (LINK) project (2011). UK JISC projects include: 'Effective Practice with e-Portfolios' (2008), 'Effective Assessment in a Digital Age' (2010) and 'Transforming Curriculum Delivery through Technology' (2011) projects. These will be invaluable resources in defining the potential and scope of eportfolios in particular, and the digital environment in general, for assessing creativity.

Affective Encounters and Spatial Engagements: Pedagogies of Desire in e-Learning

Reem Al-Mahmood
Melbourne Graduate School of Education
University of Melbourne

How do students engage in e-learning environments? What are the affective encounters and spatial engagements of students in these environments? These questions are considered by viewing affectivity and spatial engagements in terms of hybridity of the subject-object (human-material) embrace to consider not only people but also the vitality of objects and their materiality. Two poststructuralist transdisciplinary practice-focused frameworks are used: 1) the material semiotic lens of Actor-Network Theory (ANT) (Latour, 2005; Law, 2008a, 2008b) which accents material agency, and 2) Non-Representational Theory (Thrift 2008) which draws on Deleuzean notions (Deleuze & Guattari 1988) to consider affectivity as "charged" (Navaro-Yashin, 2009) intensities. This paper draws on student data from a larger ethnographic study of four fully online postgraduate subjects at an Australian university to trace participant e-learning experiences. By exploring the salience of student affective encounters and spatial engagements through three contrasting vignettes, I open up questions to address 'pedagogies of desire' (Zembylas, 2007a, 2007b, 2007c) to explore how subjectivities and desires are (per)formed in a *'more than human way'* and how places of (e-)learning are "*affectively charged"* (Leander, Phillips & Taylor, 2010, p. 336, original emphasis). These insights can open up new ways to (re)think e-learning design and pedagogy, in theory and in practice.

Keywords: Spatialities, spaces, place, engagement, affect, e-learning, Actor-Network Theory, Material Semiotics, Non-Representational Theory, Pedagogies of desire

Opening encounters

How do students engage in e-learning and e-teaching environments? What are the affective encounters and spatial engagements of learners in these environments? These questions are the focus of this paper drawing upon a larger ethnographic doctoral study exploring e-learning and e-teaching spatiality and identity intersections in an Australian higher education context. Understanding affective spatial engagements of various e-learning environments beyond design *in theory* demands exploring participant experiences in *actual practices* across various locales (Ellis & Goodyear, 2010). Much of the literature on e-learning tends to bypass the affective and emotion realms, tending towards more instrumental and measurement influenced study designs. The few studies dealing with affect and emotion in e-learning have tended to relegate these to the psychological realm (O'Regan, 2003), and more recently to the physiological (Shen, Wang & Shen, 2009). In contrast, this paper considers the affordances of viewing affectivity and emotion through the material semiotic lens of Actor-Network Theory (ANT) that takes in the materialising processes of the world, as well as the lens of Non-Representational Theory (Thrift 2008) to consider them as "charged" intensities (Navaro-Yashin, 2009), to move them beyond purely psychological states that locate them solely within an individual. By drawing on

ANT, which accents material agency where material objects, like human subjects, take on different enactments in different locales and practices, and by drawing on NRT, affective intensities and spatial engagements across various e-learning practices are 'traced'. By exploring the salience of these affective encounters and spatial engagements through their various sociomaterial practices (as hybrid arrangements of people, objects, texts, etc.), we can come to see how subjectivities and desires are (per)formed. Insights gleaned can inform educational design and pedagogy in theory and in practice. With this aim, firstly, the theoretical underpinnings and definitional ground of this study are discussed; followed by the study's design. Then, three vignettes are discussed; followed finally, by some implications for encouraging encounters in e-learning.

Definitional and framework encounters

The theories used in this paper are both poststructuralist combining the material semiotics of Actor-Network Theory (Latour, 2005; Law, 2004, 2008a, 2008b) with Non-Representational Theory (1997, 1999, 2008) that invokes the work of Deleuze (Deleuze & Guattari, 1988; Massumi, 2002a, 2002b; Thrift, 2006, 2008). Both are process-based ontologies that accent practice. ANT and NRT are both situated in a performative world idiom (as distinct from a representational idiom of a *world out there*) where the world *emerges in relation* with/to every*thing*; nothing exists independently of their relations. Both of these lenses 'perform' realities which see them as emergent in practices. Hence, their underpinnings are a performative relationality (Cooper 2005) where everything emerges *in-relations*. In addition, hybridity of the subject-object is embraced, and entities not only emerge through practices, but through arrangements of people, materials, spatialities, and so on. ANT's focus is on "How the materials of the world (social, technical, documentary, natural, human, animal) get themselves done" (Law, 2008b, p.632). However, ANT in its material semiotic emphasis misses the richness of affectivity and emotion. As Mutch (2002: 483) has it, "actor-network perspectives fail to escape … from the level of process"; and lacking an "ontology of depth" (Mutch 2002: 486), they fail to recognize "the relationship of persons with society" (Mutch 2002: 487). "ANT has a flat view of human agents, reducing them to effects and denying the embodied, emotional nature of human existence" (Mutch 2002: 487). NRT, in contrast, aims to 'capture' the affective and embrace human imagination and inventiveness, which can be 'lost' in ANT. NRT tips ANT's apparent flat ontology towards a more human-centred positioning whilst still accenting material practice. As Thrift (2008, p.276) comments, "I take the presence of objects to be particularly important because they provide new means of linkage … new folds, if you like". The strength of NRT seeks to consider the "more-than-human, more-than-textual, multisensual worlds" (Lorimer, 2005, p.83), where the focus is on life's "expression in shared experiences, everyday routines, fleeting encounters, precognitive triggers, practical skills, affective intensities, enduring urges, unexceptional interactions and sensuous dispositions" (Lorimer, 2005, p.84). ANT and NRT both *embrace the more than human* (Lorimer, 2005; Whatmore, 2006) and complement the other, allowing the material and human imagination to be accented, in their hybridity.

Consequently, taking on a performative relational worldview means that "identity may be conceived as an ongoing process of hybridity, in which one's sense of self is continuously made and remade" (Massey, 2005: 10). Subjectivities, spatialities and materialities emerge as a result of the relations between entities – material, spatial and human (Massey, 2005, p.10; Crang & Thrift 2000) – altogether hybrid. Subjectivities are not essentialised and seen as residing within an individual. Rather, we can talk of extending the boundaries of our skin (Haraway, 2006). Likewise from this worldview, space/place (Massey, 2005; Murdoch, 2006) become dynamic and emergent, rather than merely static bounded entities (e.g. Al-Mahmood, 2006, 2008a, 2008b; Al-Mahmood et al., 2006; Burbules, 2004a, 2004b; Hubbard, Kitchin & Valentine, 2004; Kitchin, 1998).

Significantly then, how are affect and emotion addressed from this performative relational stance? The term emotion often involves interpreting how one feels about an experience (Zembylas, 2007b). Whilst there is "no stable definition of affect" (Thrift 2008, 175), Thrift (2008, p.116), suggests that affect "is not simply emotion, nor is it reducible to the affections or perceptions of an individual subject". He takes on a Deleuzean interpretation where "affects are not feelings, they are becomings" (Deleuze, 1995, p.137 cited in Thrift, 2008, p. 175) that go beyond "the inner world or interiority of the human subject" (Navaro-Yashin, 2009, p.12). Affect and emotion then are performative and relational rather than residing in individuals alone. In seeing affectivity and emotion through a sociomaterial lens, they extend beyond purely human subjectivities — embracing energies and sensations that are "discharged through objects and spaces" (Navaro-Yashin 2009: 12). They are intensities, sensations or energies that can be discharged through objects and spaces "making it possible to read many other things, such as space and the environment, as affective" (Navaro-Yashin 2009: 12) in line with Massumi's (2002a) focus on sensation and affectivity and embodiment. It is the realm of affective encounters and spatial engagements of e-learning that I aim to explore towards understanding *Pedagogies of Desire*

(Zembylas, 2007a, 2007b, 2007c) that highlight how subjectivities and desires are (per)formed in a *'more than human way'* and how places of (e-)learning are "*affectively charged"* (Leander, Phillips & Taylor, 2010, p. 336, original emphasis). I aim to open up spaces for e-learning "sensescapes" (Büscher & Urry 2009) to explore how "being-in-place" (Malpas, 1999, 2008a, 2008b) and affectivity are (per)formed. Armed with these sensibilities, I outline the study's design next.

Methodology and method encounters

I have worked the "methodological frontiers" and have crossed boundaries (Brownlee & Irwin, 2011; Goodyear, 2011; Markauskaite, 2011) in the methodological choices (Markauskaite, Freebody & Irwin, 2011) adopted. I have drawn on transdisciplinary approaches from ANT and NRT, traversing the discipline boundaries of Human Geography, Education, Visuality, and Philosophy. Goodyear (2011) alludes to the valuable insights and contribution that ANT and NRT can potentially make to "educational research futures", as "ANT encourages us to open our minds to possible redistribution of work amongst humans, digital and physical actants" to address educational learning complexity (Goodyear, 2011, p. 263). He highlights the attraction "to the insights that flow from thinking about educational systems (a) in terms of relationships that are simultaneously material and semiotic and (b) as depending upon the ongoing 'performance' of their constituent elements" (Goodyear, 2011, p. 262, footnote 6). This requires "ecologies of interweaving physical, digital and human resources" (Goodyear, 2011, p. 258). My aim in choosing this small scale study is in line with Goodyear's (2011) prediction that educational research will move away from *golden standard* large scale studies and hypothesised studies towards smaller scale design studies to inform rich design patterns (Goodyear, 2005) for interpreting and producing effective (e-)learning environments (Goodyear, 2011, p. 260).

This study involved a multi-sited ethnography (Leander & McKim, 2003; Marcus, 1998) of four fully online postgraduate subjects in an Australian university. Ethnography was chosen to facilitate prolonged and immersive exploration of participant e-learning engagements. Physical ethnography (Marcus, 1998) and virtual ethnography (Hine, 2000, 2005) were used to gather and observe the minutiae of participants' everyday practices across physical and digital spaces. Participants were invited to participate in the study, and methods to deal with physical and digital (im)mobilities (Büscher & Urry's, 2009; Büscher, Urry & Witchger, 2011; Sheller & Urry, 2006) to capture various actors across physical and digital spaces were used. These methods included participant interviews, participant observation, photographic data, and participant reflections across physical and digital spaces over a period of 6-10 months. Data were collected from 24 participants — 19 online postgraduate learners, and 5 teaching staff (2 females and 3 males) with a range of ages and teaching experiences. Daily scheduled observation diaries of the online subject sites were kept, and participants were invited to keep reflections and provide images of their various learning locales. Various movements, or 'travels", as Büscher and Urry (2009, pp. 101-102) suggest of people, ideas, technologies, etc., were explored. A wealth of detailed data were amassed, and whilst the aim was to add to the world through ANT and NRT lenses, glimpses into human, spatial and artefact interactions were 'traced' (Markaskuite, 2011, p. 244), whilst attempting to 'capture' and '(re)present' the sensuous textures of the fleeting, the sensory, the affective, and the spatial ambiences. The three contrasting student vignettes chosen (a la Al-Mahmood, 2006, 2008a, 2008b; Thrift, 2006) were based on detailed thematic analysis of face-to-face in-depth interviews/conversations (each ranging from 1.5-2 hours each), as well as on photographic data and student reflections.

Affective encounters and spatial engagements

In the three vignettes that follow, I explore (dis)connections, (dis)locations, and (dis)mantlings, tracing passions, desires, disconcertments of being *no-where*, *in-between*, *in transit*, *in hope, in anticipation*. I consider how spatialities and materialities (per)form e-learning as they hold/disrupt and (dis)connect various boundaries of physical and digital spaces. I explore (dis)engagements in terms of private/public, presence/absence, visibility/invisibility, and isolation/connectivity (Burbules, 2004a, 2004b, 2006a, 2006b; Enriquez, 2009) to show the multiplicities of technological effects that *affect* bodies and subjectivities as borders and boundaries shift. Indeed, "We live in a world of compartments and borders which may be more fluid and elastic, easier to cross than in the past, but they are out there all the same, impacting upon the minutiae of our daily life practices, identities and affiliations"(Newman, 2006, p. 183).

Vignette 1 ~ (Dis)Connections: Sink or swim …?

I introduce, Lillian, an international Chinese student in her early twenties studying and living in Australia. She is a softly spoken, poetically expressive international student who has majored in English Literature. The descriptions that follow show how she conceives and *'does'* boundaries as a way to focus her thinking and e-learning within the privacy of her home. The focusing "white wall" is a welcome aspect for her. Hers is an experience of how boundaries function as focusing and concentrating (Figure 1).

Figure 1. Connecting and Focusing

> I always studied in my room and always, my room is narrow, not narrow, my room is maybe 15 metres square …. and only a very simple room, just with a table, chair and a bed, something like, very simple and I put my table, for example, this is the room [draws this visually], and I only have a window there and my bed … and my table is at the corner of the wall because I thought that is good when I am working, I just face the white wall, not window, because … I like to look out of the window and not concentrate on my work.

The privacy of her home and its focusing aspect is productive for Lillian as she highlights her unease about taking her laptop to university to study in a public learning place as defocusing.

> …. sometimes I bring it [the laptop] to the campus … I'm that kind of person from my college time … I don't want to study in a public place. I mean, I don't know why. I just want to stay in my room and study in my room. So working in the public lab, I can't focus. I can't concentrate. I always feel other people they are waiting for the computer.

For Lillian, the online class is through her laptop that connects her with the lecturer as she says, "The classroom is only the laptop for me — just the laptop".

> … I just feel there is … a line, a power line connecting me and Brian [the lecturer]. That's it. I sit at the other end of the line and he's sitting at the other end of the line. … I just check the mail box and if I found him [the lecturer online] [then] I copied and I saved every email from him …. because I think that's a kind of … learning material …

She is acutely aware of the "material politics" (Law & Mol, 2008) of how the Internet is changing how people experience and go about learning, saying:

> I feel all the communication is just … typing, and I click the Enter and Send, and that's a message. So I think computer[s] really [the] Internet and computer[s] really change the human world …. the behaviours and … peoples' thinking patterns … dramatically, totally, radically…

Typing, clicking and sending in the e-learning medium changes the sense of engagement; despite its efficiency, it creates a *feel of commercialism*. Here, we witness realities of efficiency coupled with realities of commercialisation abutting each other, as Lillian highlights below.

> I think that makes it more efficient …. The teacher can go out and leave and do his own business, but still he can teach and I'm also, I mean, efficient at doing this, and I type out and didn't go to the classroom and sit in [for] three hours … But also I think that makes peoples' interaction and communication less and less and so makes you feel other things are more commercial …

She further highlights the changes to the student experience, in spite of being potentially isolating and lonely, in developing independence and resilience commenting on a Judy Horacek cartoon of a lone person sitting outdoors under the stars sitting with her laptop looking at the screen of stars (as part of a warm up interview conversation activity).

> For me, this is firstly … loneliness. Yes? And this person is struggling by herself and without immediate help. The help is only through online and other help is as distant as the stars from other planets. So that's a kind of distant help that you kind of feel the touch the personal communication. So that's very lonely and the people should be strong enough so the person should encourage herself … should carry on and comfort herself. You're the only person in the planet … but I think other persons in other planets in other stars, they are also very lonely. Like this. So that's communication between lonely planets. So I think [the] Internet and computer just make every person like living in his own planet. Because you can get anything from the Internet, so that means [the] Internet is enough for you to get anything. Okay, that's adequate for you. So people needn't go outside to communicate with other people in this sense. But that also makes people isolated and lonely.

The sense of isolation is alleviated in the immediacy of synchronous online responses from her lecturer, when he is online, as she highlights.

> … I send my assignment to him [the lecturer] and he asks me to ask him whether he has corrected my assignment, okay so that's 2.00 in the morning and I say okay, I can send him an email on the day, so I send him the email and then quite surprisingly he returns [a reply] immediately, so I feel …. I feel oh, this man is very interesting … that is the first time I feel really quite personal, I mean not impersonal but just a person with characteristics, and then I just write back to him, I say "what a surprise, I didn't expect you [to be] still at the computer now", and he also sends me back an email and he said: "I am also surprised, a student needs to have sleep". Yeah, and I feel he is so lovely, and [at] that time I mean [it] shortened our distance so that is good.

Yet even more significantly for Lillian is the solace and company provided by her laptop computer, saying, "… [the] computer is just like a tool of learning but it is also like good company, when you are lonely … you just stay up very late, alone in your room and [the] computer is the only thing accompanying you".

So for Lillian, as a locally residing international student in Australia, the e-learning experience provides her with connection to her lecturer, and her bounded home helps to maintain her focus and concentration as well as her private personality preferences, albeit that she would be willing to participate in the online public space should her teacher ask it of her. Hers is a strong "isolated connectivity" (Enriquez, 2009).

> Yes. I will tell the teacher … and say, I'm a very self-conscious person and I will say I do feel there's always, I mean, how do you say that, I mean, I'm on the stage alone and so the teacher and other students will observe my behaviours on the stage. So if I didn't do well, I will feel very nervous because I will feel people notice that. Okay, so I hope I can feel safe in the surroundings and supported. So I think I do not say every person will speak out and bare their personalities and bare their feelings, but I will do that if the teacher asked me to do that. I want the teacher to understand me and then the teacher can interact with me and help me according to my introduction. That's it.

Lillian's study spaces have her studying skilfully, diligently, perseveringly, with dedication and commitment, mirroring the stereotype student behaviour of a newly arrived international ESL speaking student. Lillian uses the metaphor of water when she describes her experiences online. There is a sense of respect for the lecturer and that to learn is to practise skills, persevere, and "swim" so as, above all, "not sink". For Lillian, there is solace in the visibility of other peers and their struggles too. She is not alone. We see the perceived importance of the student-lecturer relationship in sustaining students.

> … my metaphor for [Bernie's subject] should be connected compared with [Barrie's subject]. In [Barrie's subject], it is just like I was swirling in a pool and I am struggling; I don't know how to swim … and then in [Bernie's subject] after [Barrie's subject] experience, I am a little bit more skillful about how to survive in the water but still sometimes [I] panic when there are waves, but sometimes when I look around and find the other peers, they are also struggling in the water, okay I feel not so nervous then, and I think, "okay, I won't die because this is only in a pool, and the teacher is just practising, making us practice, learn by practising, so I won't really die", but yes, still you can say some students, they swim very well and very fast, and I am just beginning to learn how to swim and … just not sink.

I ponder Lillian's evocative metaphor of water, and swimming and how an online lecturer might know that a student is drowning or unable to swim well or quickly enough in an online world? What cues can they pick up in a purely online medium? What anchors can they provide? And how are these translated online, across cultures, and geographic spaces, and especially for those students who may not have English as a first language?

Vignette 2 ~ (Dis)Locations: Encaged and exasperated …?

In this vignette, I discuss one of the haunting lingering impressions of a 23 year old 'digital native' (Prensky, 2001a, 2001b, 2009), a Chinese international student, Koko, interviewing her face-to-face in her room in her shared household. Her online experience was extremely isolating and her comments were tinged with exasperation (missed in the mere textual translations of her words). I've assembled interview comments to illustrate her metaphor. Online simply does *not do* here; nor does it address Koko's need for embodied engagement and the salience of lecturer and student physical presence (McWilliam & Taylor, 1998). Her words are hauntingly striking when she says:

> They just give you a computer in a cage, that's not enough. You always live with a computer, *it's not real*! They provide you with a computer in the cage, but the computer is just a box, the computer tells you [about] the blue sky, the green grass, the computer provides you with the picture of that, but *it's not real*! *It's not real*! So it's just like the lecturer through the online course, they give you the material, they answer your questions, but they do not solve the problem, so *it's not real* …" (original emphasis)
>
> I don't want to use the prison (laughter) because prison is a little bit serious, [it's] just like a cage. You can see all things, you can see, you can hear, you can find yourself … you're just like a tiger, which is in a cage, which lives in a cage; you can find all the beautiful sky; you want to go outside; you want to touch them with your hand, but at last you are just waiting for them [online lecturers] to give you something. And sometimes they won't give you enough things you really want. You have full energy, but you are living in a cage …

I'm reminded of Rilke's (1984, p. 25) poem, "The Panther", "His vision, from the constantly passing bars,/has grown so weary that it cannot hold anything else./ It seems to him there are a thousand bars;/and behind the bars, no world./ As he paces in cramped circles, over and over,/ the movement of his powerful soft strides/ is like a ritual dance around a center/ in which a mighty will stands paralyzed…". And yet for this online student, unlike Rilke's tormented panther, Koko's will *was* mobilised. She sought institutional places of libraries and wired learning centres to connect with others to sustain her in the e-subject and to excel at it, despite her exasperations. Koko seeks other actor-networks of humans, materials, and spaces. She finds these by relocating her online study by taking her laptop to the university library campus to be present with other university students to connect her with *real* people to find a way to live through the online experience and move beyond the encaged feeling she gets from the LMS (Learning Management System) space in her little room (Figure 2). The vibrant university library spaces and the flurry of noisy flexible library learning hubs which sustain her connection and reduce her sense of isolation become vital actors in sustaining her e-learning.

However, during library closure when she is at home, she resorts to Marty — a teddy bear — to reduce her isolation and the solitariness of doing the online subject, suggesting that he keeps her company when she's "studying all alone at night" — a surrogate companion of sorts perhaps, albeit non-human. This is not so different to Haraway's (2003, 2008) works on companion species where "becoming with" is "a practice of becoming worldly" (Haraway 2008: 3), albeit in Koko's case "*becoming with"* a teddy bear (an inanimate sensuous object).

In figure 2, I collage one of her rescue artefacts in the photographs. She asks me to take digital still images of her room as she places her teddy bear, Marty, in various positions around her bedroom/study amongst her other vital materials.

Figure 2. Marty with the Laptop!

I have mused over Marty, this teddy bear and what to do with him; I do not want to place him under erasure since he is so integral in Koko's account, for his mediating role is in anchoring her to a pseudo-human companion when she studies alone online at night in a foreign city. And what of the other objects here – the flags on her wall, a map of the world and various other sustaining artefacts, mugs, laptop, and …? Perhaps Marty, helps *secure* her in the online learning world in which she felt "caged" more than I could have thought possible.

Vignette 3 ~ (Dis)Mantlings: (Sacred) Rituals …?

I highlight how e-learning and e-teaching replicate *formalised rituals* of *traditional* academe. In some e-learning spaces various lecturers and students enact positions of "being the *good* student" or "performing *the student*" role in response to a lecturer *performing a teacher role*. For some, partaking in online question-answer interactions is seen as ritualised *mechanical performances* of *going through the motions*.

I juxtapose Paul's various identity expressions and affective spatial encounters and impressions in the different e-learning spaces of private e-mail interactions with his lecturer and the public online subject forum with his peers and lecturer in Table 1.

Table 1. Juxtaposing email and LMS forum spaces

Emails — "I'm jumping through hoops!"	**Forums — "I'm 'being held' somewhat!"**
"I can't even remember his [lecturer's] name I felt a bit like I was 18 years old and back at university and trying to guess the right things to say and really having no idea what I was talking about and what I was meant to be saying and what would meet with the lecturer's approval. It felt very much like a performance that I was involved in. That I was having to send this weekly email that would be judged as suitable or not suitable and I felt often like if I guessed the right answers then I'll get a tick. And, if I got a couple of responses back in a theoretical, de-personalised way that I thought were brusque, it put me off the whole experience. It felt like I was doing this because I had to and because I had to get a pass to get to the thesis but it wasn't actually particularly helping me with anything. It felt like I was jumping through some hoops because the university demanded it. Yes, being a novice and being in someone else's territory that wasn't my own and that, you know … maybe I was a bit of a fraud by being there because I was just desperately trying to work out what was expected of me and not really knowing. It would have been better to have more of the experience of other students. I was constantly trying to work out what was going to be good enough and how much I would have to do. And I was getting back these responses that were, I know … as a teacher myself I was aware of the lecturer of the subject kind of reading through it at a hundred miles an hour thinking, "Oh, I better comment on four points, this one, this one, this one, that one. Okay, I've said something to him and sent it back." You know, I felt like I was performing for him and he was doing the teacher role for me of doing sort of the four responses per text back, so there wasn't any sense of mentoring or any sort of real guidance.	"Even where there was the forum, it still felt like I have to produce a certain amount of text, get it there on the website, make sure it's not less than everybody else's, make sure it's reasonably coherent. I didn't feel like I was particularly interacting by doing that; I felt a bit like I was performing. But the notes that we had were I thought produced by someone who was mindful of communicating in an accessible, human sort of a manner so that they talked through the issues in a very engaging and real and conversational way … I felt like it was actually assisting me and developing my own thinking about my research. There was first person pronouns used and it was someone talking to me about my experience of research and someone warning me, "You might experience this, you might experience that"… And I got some very good email support from the lecturer and I also got some very good telephone support from him. And when you asked me about the forum And who I was on it I thought it was a very interesting question. The forum was an interesting sort of thing because I was writing to other people who were presumably professionals and postgraduate students so, yeah, there was a bit of "this is my professional environment." And there was some status and pride to be protected in talking about that. Interesting. I think I realise, and I hadn't thought about this before, but I guess what I was doing in writing those forum entries each time was being fairly careful

Occasionally he would write back and say, “No, this is not, bold in capitals, what the text says”. And I’d just think, “Stuff it, I don’t care what the text says anyway I just want to get my thesis done”, So … It felt detached and it felt somewhat authoritarian.” Paul	to show that I was competent and articulate and thoughtful and that this was my domain that I was working in and I have quite a bit of expertise about this and you know, I’m a teacher and I’m a professional. So, yeah, there was that element of performance … and I felt that Bernie was quite respectful of our experience and knowledge ….. so nourishing is the word that comes to mind.” Paul

It is perhaps paradoxical that despite the private individualised one-to-one email interactions between Paul and his lecturer — this only served to intensify his *connected-isolation* rather than connectedness. He was connected, yet isolated — the relationship via email seeming “formulaic”, configuring him to play “the good student”. Issues of authenticity and trust prevail for some in hypertext worlds (Bayne, 2005, 2006a, 2006b; Bayne & Land, 2000; Kreber, 2010; Land & Bayne, 2005a, 2005b, 2006, 2008).

This contrasts with suggestions that email provides a *hyper*-intensification of connection and intimacy — a “hyper-real”, where relationships are intensified in the absence of-face-to-face interactions (Milne, 2003) to provide an intensified “presence-absence” (Enriquez, 2009). A continuum of impersonal to hyperpersonal in CMC is possible (Walther, 1996). Yet in the online public discussion forum, in the presence of other online students as well as the lecturer, Paul felt somewhat “held” whilst being *careful* to present more of his professional identity (rather than his student self). Paul’s identity shaping and projecting is mediated through the medium type here — private email learning spaces versus public online LMS forums (further significant actors).

When asking Paul about his perception of the e-learning medium, his response extends his earlier comments. “I don’t actually know that I have a sense of being in a space when I am in the virtual world. I don’t really. … that I am working at the time? I find it hard to find an answer to that question I would have to say. I think I probably, I mean I think the computer for me is … yes I don’t know. I don’t know if I can answer that …”. Put simply, there is no sense of place, because for Paul there is no sense of “holding the class” through the online lecturer’s presence, or of a “relation with” the teacher, or invitation to “rest” in the online learning space. “I tend to feel that there is something that can be lacking in the online delivery that’s very important in a … classroom and to do with the presence of the teacher”, he says. The online class does not maintain a sense of “entering” a learning space, a notion used frequently by Paul, where there is a sense of boundary or threshold, of going into a learning space/place “to be held” and to be in an “energetic space”. His words remind us of the rituals of entry, “And so I really like the idea of going into a classroom”.

In describing his physical learning spaces, he says:

> Attached are a few thoughts on the sad corner of the house I refer to as my study. … it’s not a pure study, it’s also the way to the laundry and the way out to the back door and where the pet lizard is kept and where some of the kitchen stuff is kept, so it’s just … it’s off the kitchen …. It sits in the back room of my house which kind of doubles as a study ….

Paul commenting on the perception of the online subject says:

> … it was the over here, separated from everything else that is going on in my life and my work, and everything else, is this little nuisance that sits on the computer that has to be got through …”

Paul elaborates in an email exchange about his study:

> … The space in which I work is located at the back of the house. It is essentially a thoroughfare — the door behind the desk in the photo leads into the laundry. The space also opens onto the kitchen, the toilet and the back yard. It is, in a word, unsatisfactory — too much noise, constant traffic, no privacy and insufficient space, a product of too many people living in too small a house ….
>
> … It is quite ironic that I should bang on about the sacredness of learning space, when my own 'refuge' is so beleaguered — or maybe it's no coincidence at all …

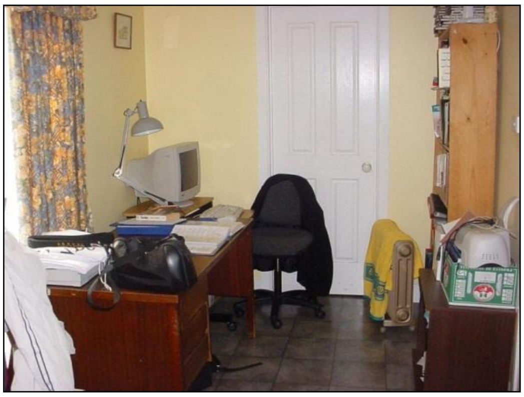

Figure 3. Paul's sad corner of the house

Paul provides some very rich descriptions of his learning experiences and of his physical and digital learning worlds. The profound effect of his martial arts training and embodied experiences of ritual and respect have influenced his own teaching philosophy — expectations which he carries with him, as a student into the online class environment. However, the lack of an online student-teacher relationship for him, and the lack of rituals and embodied practices, renders the online learning experience as diminished and *lacking*. Paul connects or translates his martial arts views of the teacher-student relationship expectations to the online environment, but finds it significantly lacking, for there are no spaces to be "held", to be "contained", so the e-learning environment never reaches this ideal. His sense of being in a "place" is absent in the e-learning spaces. The contrast with his physical space seems to create this yearning perhaps for the ideal. His need is for embodied online relational teacher presence to create a *sacred learning-teaching place*. For Paul, the online space never becomes a learning *place*. Arguably, Paul remains feeling extremely isolated and alone during the online subjects. And reflecting on Paul's desire to be "held" and "contained" in a respectful, restful, relational way, I wonder how can we translate teacher presence in e-learning spaces such that they might become "sacred learning places"? From Paul's perspective, the impossibility of achieving this is one that concerns embodiment in its fullest sense, saying:

> … there is potentially some schizoid dynamic going on in partaking of the virtual world .... If I do go in there, it's, as I said, compartmentalising things, that I can sort of put a bit of my intellect and maybe a tiny amount of my emotion and my everything else in there, but I am consciously splitting off that part there and putting it there and holding a great deal of myself separate. … I believe the most effective teaching-learning interaction is one that engages the whole person — body, mind and spirit. And I don't know how that gets involved in a virtual process. Maybe it does, but I can't envisage it.

Desiring encounters

I have juxtaposed these vignettes to highlight the affective and spatial realms of participant pedagogical experiences (Zembylas, 2007a, 2007b, 2007c) and their (e-)learning impacts (Zembylas, 2007c; Zembylas & Vrasidas, 2005). Through these vignettes, we glimpse a multitude of participant desires along with various nuanced subjectivities that emerge. This forms a 'pedagogy of desire' that mobilises the "creative, transgressive and pleasurable forces within teaching and learning environments" (Zembylas, 2007c, p. 331). This enables "a new view on affect in education as a *landscape of becoming*" (Zembylas, 2007c, p. 331, original emphasis). In these vignettes, participants, materials and spaces configure *radical* selves (Zembylas, 2007c, p. 331). Here we see that desire, subjectivity and pedagogy are relational – they are inextricably linked and co-shape the other. Zembylas (2007c, p. 338) affirms this highlighting that "Desire produces pedagogy as it produces subjects …. A pedagogy of desire is therefore not based on a notion of desire as being a state, position, or feeling towards teaching and learning practices, but it is a pedagogy of the subject and the relation between subjects and objects and artefacts".

The material embrace of the subject-object hybridity in the vignettes highlights the material politics of practices – the *politics of things* (Fenwick, 2010) – where people are not placed "above materials (as the creator or user) but among materials" (Sørenson's, 2009, p.2). Hybridity dismantles the boundaries of humans as set up "in opposition to things" (Dolwick, 2009: 35) to act "'on' things" (Dolwick, 2009, p. 35, original emphasis) to consider how humans act "with, through, or in response" to things (Dolwick, 2009, p. 35). There is a vibrant materiality (Bennett, 2010) and vitality of objects (Knorr-Cetina, 1997; Pels, Hetherington & Vandenberghe, 2002; Turkle, 2007, 2008a, 2008b) and spaces that is highlighted in these vignettes. These all configure e-learning spaces as "*affectively charged places of learning*" (Leander, Phillips & Taylor, 2010, p. 336, original emphasis). We might then need to consider how and in what way we might make university e-learning spaces and designs "affectively malleable" (Leander, Phillips & Taylor, 2010, p. 341) to encourage *engaging* encounters for participant desires. Insights into these spatial engagements and affective encounters may well inform language design patterns (Goodyear, 2005; Goodyear & Retalis, 2010).

Encouraging encounters

How might we as universities, lecturers, and designers then ensure that all students have access to engaging and pleasurable e-learning experiences? This study highlights that e-learning has multiple enactments, and that not all students *connect* or *engage* (Prensky, 2005) in the same way in e-learning environments. What is striking in these vignettes is that despite student-centred learning mantras, there is centrality of the teacher/lecturer role and presence. This is not only pertinent for the two Chinese students, but also for the local Australian student. Standard ritual practices of traditional academe — when/if they are replicable online — can provide reassurance and sustenance to facilitate e-learning as a welcoming and familiar space (in an *e-classroom*). Every*thing* (from learning, to engagement, to first impressions online) is held in delicate balance — from the nuance and texture of a word to the timing of responses; everything is judged, interpreted and waited for by the students — indeed, *the human matters through the machine*.

Moving the student-teacher relationship to standardised commercial online LMS text-dominated platforms that attempt to replicate *traditional* university rituals can be problematic in that they can be (de)stabilising experiences. Through the LMS, the university inevitably becomes *(hyper)textualised*. We need to find creative ways to imbue e-learning 'environments' with the liveliness of space (Massey, 2005, p. 189) in creating more vibrant platforms that engage and entice students in terms of spatial encounters. For our educational designers, this might mean not only creating replicable traditional classroom spaces, in secure places of enclosure, but also to create opportunities for more exploratory and dynamic open spaces that move beyond current standardised LMS platform designs. How might we provide online environments that allow for public and private spaces, for *sacred* rituals of entry beyond passwords, towards open, inspiring and exploratory e-learning spaces? Indeed, these "less familiar and less stable environments" (Hannon, 2009: 428) of LMSs could provide new pedagogies and paradigm shifts (McLoughlin & Lee, 2008) that might risk encouraging radical transformations.

In addition, within the LMS spaces, how might we create opportunities for welcoming international students living in the host cities of the e-learning university, and indeed all students? We need to think about not only how we use the digital spaces, but also how we might integrate them with existing physical university spaces. Altogether, connectivity and engagement can be common mantras (and myths) that influence social justice and access issues in e-learning environments (Zembylas & Vrasidas, 2005; Vrasidas, Zembylas & Glass, 2009). This impels us to consider the complexities of spatialities and how they influence learning. *Ultimately, online and offline practices are mutually imbricated*, so we need ways to move beyond thinking of the e-learning medium in binary terms of a physical/digital divide so that we might engage online students with multiple university spaces. It may insightful to consider the language taxonomies that our online students use to describe their actual e-learning experiences of the online learning spaces and those that describe their ideal e-learning environment. For Paul, it was about "*entering* a space" and "going *in to* a space", and yet the waiting and visibility/exposure for Koko merely created for her a sense of "being watched", "being fed" and feeling encaged within the boundaries of the LMS. Yet, for Lillian, the e-learning space was a "sink or swim" space, and a place to learn with others, with all the connotations of fluidity, panic, survival and so on.

Tracing student experiences and analysing them can certainly (trans)form and contribute to how we might (re)think our educational design platforms and pedagogical practices. Altogether, we need to open up spaces for understanding *spatial and affective encounters and engagements based* on our students' experiences. Using the metaphors of these students, I have shown how different practices emerge — fragilities unfold — where material, spatial, and human *matter*ings are (per)formed — sacred spaces are sought, found, made, and lost. How might universities facilitate *holdings, swimmings*, and spaces for students *lost at sea* online — beyond online *lifelines*? For the fates of *those lost — online/offline, beyond lines* — seeking buoyancy — *"so as not to sink and learn to swim"* in Lillian's words — is what lingers in precarious balance.

Let us aim to move differently to embrace the *more than* — beyond human/material divides, and beyond online/offline divides to embrace ‘pedagogies of desire’ that can transform (e-)learning.

Acknowledgements

To the participants who so generously contributed to this study, I am indebted. I am also appreciative of the valuable feedback by the anonymous reviewers.

ICT-assisted multi-campus teaching: Principles and practice to impact equity of experience for students

Alan Anderson
Centre for Teaching and Learning
The University of Newcastle

Elizabeth Date-Huxtable
Centre for Teaching and Learning
The University of Newcastle

Given the range of ICT-assisted delivery options available today, the uninitiated might assume that teaching across multiple campuses no longer presents any significant challenges. Further, it could be argued that terms such as multi-campus and distance teaching have less relevance now that ICT enables flexible learning beyond the time and spatial confines of the physical campus. In fact, research literature indicates that multi-campus teaching continues to present some unique pedagogical, technical, learning support and administrative challenges. Based on a search of Australian University Web sites, this paper examines principles, practices and challenges for ICT-assisted teaching and learning at multi-campus institutions, at the same time noting a lack of comprehensive online resources that address ICT-assisted multi-campus teaching as a distinct category of flexible learning.

Keywords: Multi-campus teaching, learning, higher education, education technology

Background

Information Communication Technologies (ICT) can enable flexible learning beyond the time and spatial confines of the physical campus. These “improved access” benefits are widely acknowledged (Allen & Seaman, 2007, p.2) even by educators who raise concerns about “the push for flexible learning” (Lynch & Collins, 2001, p.1). While in respect to educational value, recent studies have produced evidence of online learning that has surpassed face-to-face teaching. Based on a meta-analysis of over one thousand empirical studies of online learning the US Department of Education found that, “on average, students in online learning conditions performed better than those receiving face-to-face instruction” (2009, p.ix). Similarly, a case study conducted by the Australian Government Department of Education Science and Training (DEST) Programme Research, Analysis and Evaluation Group found that “online education provided a powerful pedagogical tool …” (DEST, 2011, pp.150-151).

In the light of promising evidence about the educational value of online learning, and faced with increasing student demand, many education institutions in Australia and internationally have "tended to see 'flexible delivery' as a panacea …" (DEST, 2001, p.iii). It follows, therefore, that the uninitiated might assume the solution to multi-campus teaching is to simply "put it on the web" (Lynch & Collins 2001, p.380). In fact, best practice literature shows that effective online and blended learning involves much more than simply uploading books and multimedia with some links and ad hoc questions "added to make them 'interactive'"(Gayeski, 2005, p. 98 in Herrington et. al. 2007, p.1).

According to Ebden (2010), universities have drawn largely on "technology-driven solutions to overcome some of the challenges posed by multi-campus learning but these pose their own set of challenges" (p. 267). For example, writing in relation to alternative methods trialed at Deakin University, "such as narrated PowerPoint presentations and videoconferencing in place of face-to-face lectures, and e-Live tutorials instead of face-to-face tutorials," … Ebden notes that "no solutions or combinations of solutions were deemed instrumental in addressing all of the challenges adequately" (ibid).

Cognizant of Ebden's observation concerning a lack of evidence to guide the development of multi-campus course delivery, the present study was designed to examine how Australian universities are endeavouring to foster good practice and equity in their MCT operations through their online resources and relevant policy documents.

It was anticipated that the results of this web-search could in turn inform the development of evidence-based resources and guidelines for ICT-assisted teaching across multiple campuses at the authors' home institution.

Method

A qualitatively driven mixed method case study approach was adopted to "illuminate contextual complexities and nuances on multiple levels" (Hall & Ryan, 2011, p.1).

A web search of policies, strategies and resources used by Australian universities for multi-campus teaching was conducted using the same search strategy for every university site. This was done by first ascertaining whether the university was a multi-campus institution, then searching the university's web pages using "multi-campus", "multi campus", "multiple campus" and "cross-campus", also "multi-campus teaching" and multi-campus policy." This search was of publicly available information and may not reflect the internal policy, strategy and resource generation processes currently in action.

Additional insights into how institutional policy and principles are interpreted and applied in practice were gained through semi-structured interviews with staff (n = 15) at the authors' home institution. To gain a cross-discipline perspective, participants were recruited from a variety degree programs: Mathematics; Music; Education; Information Communications Technology; Indigenous studies; Marine biology; Cultural studies (Media); Physiotherapy; Nursing; Pharmacy; Architecture. Transcripts and quotes extracted from transcripts were routinely coded to help preserve the anonymity of participants. Using an "interpretive approach" (Neuman, 1997, p.71), inductive category coding and comparing of meaning across categories" led to "an understanding of the people and settings being studied" (Maykut & Morehouse, 1994, p.135).

Results and discussion

Results of the web search indicate that there are 37 (of 42) universities in Australia that have more than one teaching campus. Readily accessible were the publically available web pages or documents of five universities that have policies, strategies and resources specifically addressing MCT (Table 1, also highlighted in yellow in Table 2). In addition, two universities have developed policies and strategies to support specific technologies used in multi-campus teaching and flexible learning (highlighted in green in Table 2).

Table 1. Evidence of university-wide equity of experience principles for students on different campuses

University	Principles*	Recommended Strategies †	Evidence
LaTrobe University	√ x	√ x	Multi-campus Teaching by Videoconferencing http://www.latrobe.edu.au/teaching/assets/downloads/VideoconferencingGuidelinesVer6.pdf
Monash University	√ √	√ √	Multi-Campus Consultation for Unit Management http://www.eng.monash.edu.au/secretariat/policies/download/multi-campus-consultation-policy-v0.1.pdf
Central Queensland University	√ x	√ x	Multi Campus Roles & Responsibilities http://dfm.cqu.edu.au/FCWViewer/getFile.do?id=3105
University of Tasmania	√ √	√ √	Cross-campus teaching http://www.teaching-learning.utas.edu.au/orientation/cross-campus
Griffith University	√ √	√ √	Program leadership in multi-campus universities, http://www.griffith.edu.au/education/program-leaders

At the time of the initial web search, University of Tasmania was identified as having the most comprehensive publically available online resources addressing MCT pedagogy and equity principles directly. The essence of the MCT principles noted by most other university sites were represented in the UTAS publically available online resources, therefore, an abridged summary of these are included in the following legend for table 1. Note that * stands for Principles whilst the symbol † represents Strategies.

* Principles:

1. Equity and equivalence – Irrespective of the campus at which students and staff are located, all must be treated equitably. In addition, teaching and learning standards must be equivalent at each of the campuses.
2. Equivalent not identical – Specific learning activities can vary in the way they are taught yet still result in equivalent learning outcomes for students (UTAS, 2010, p.1).

† Strategies:

1. Learning decisions should come before delivery decisions – Decisions about the most appropriate means of delivery should begin with consideration of the teaching/learning situation and the intended learning outcomes.
2. Integrate, don't duplicate – "Multi-campus teaching is generally not about using identical strategies at all campuses." Rather, it is about using "an inclusive suite of flexible teaching/learning strategies for all students” (UTAS, 2010, p.1).

Seventeen universities have developed strategies or resources or recognise that they need to develop policy, strategies, resources and/or research related to MCT. The remaining 14 do not appear to have documents on MCT publically available online. None of the 37 multi-campus universities had markedly comprehensive publicly available multi-campus teaching resources.

Table 2. Publicly available statements on the Principles, Strategies and Online Resources used to support MCT

University	Principles	Strategies	Online resources
La Trobe University	To ensure that high quality teaching and academic support are effectively and equitably provided to students on all La Trobe campuses.	Multi-campus teaching 'Alert' brochure: "Importance of Training" and "Next Steps".	http://www.latrobe.edu.au/teaching/assets/downloads/multi-campus-teaching-alert.pdf
Monash University	With a growing number of units being offered on more than one campus, it is important that the equivalent academic standards be maintained across all sites. University of Tasmania	A guiding principle for multi-campus operations: to ensure that all students and staff are treated equitably and equivalently: http://www.utas.edu.au/university-council/university-governance/university-guidelines/teaching-and-learning-quality-issues-related-to-the-multi-campus-nature-of-the-university-of-tasmania	ALTC-funded research: Enabling and developing leadership in multi-campus universities through the development of communities of practice [at] universities [in] Cross-campus teaching	http://www.altc.edu.au/project-enabling-developing-leadership-utas-2007 http://www.teaching-learning.utas.edu.au/orientation/cross-campus
University of Southern Queensland	USQ made a commitment to mainstream the use of Virtual Classrooms into its core Technology Enhanced Learning infrastructure.	Virtual classrooms … collaborative media allowing cross-campus and multi-campus teaching.	http://www.usq.edu.au/extrafiles/ltsu/PRP/tel_flexdel/virt_classr/virt_classr.htm
Curtin University of Technology	Flexible Learning mode provides students with comparable learning experiences in respect of the course and unit learning outcomes…that are available to students through traditional campus-based methods of delivery.	In regard to multi-campus and international partnerships. Suggestions for use of Elluminate Live to facilitate individual or group meetings, mentoring, exam/assignment moderation.	http://cel.curtin.edu.au/tools_tips_training/LetsGetFlexible/email_template/Issue13_elluminate/Issue13_elluminate.html

The five universities identified in Table 1 were active in addressing the principles of equity of experience of MCT as follows:

1. Latrobe has a guide to *Multicampus Teaching by Videoconferencing*. Key principles relating to equity of experience, student engagement and the alignment of relevant content, activities and assessment to intended learning outcomes are addressed in relation to best practice teaching by Videoconferencing. The document includes advice on lesson preparation including practical student engagement strategies such as welcoming students (especially those at the remote sites), structured discussion mediated by a facilitator at the remote venue, and 'wrap up' time to clarify anything that remains unclear for students.

2. Monash University (Engineering) has a policy document titled *Multi-Campus Consultation for Unit Management* with links to other relevant policy documents (referenced in Table 1). This document provides a clear rationale and list of responsibilities for multi-campus unit management groups (key teaching staff involved in offering the unit from campuses involved). These are consistent with those outlined in the UTAS principles used as a point of reference in Table 1.

3. Central Queensland University (CQU) has a Multi Campus Roles & Responsibilities Fact Sheet that provides a concise plain language explanation of the key responsibilities of the Course Coordinator, Lead Lecturer, Head of School, Associate Deans (Teaching and Learning), Associate Director Academic Programs, Campus Directors & Heads of Campus, and Deans.

4. UTAS, similarly, has a web site that clearly articulates principles and practice information specifically focused on multi-campus teaching. Importantly, a number of these principles are unpacked to clarify how particular principles can be applied in practice. For example, in regard to equity of experience for students, UTAS note: "The specific details of an assessment task might be varied if aspects are unsuitable for a site at which the course is offered. For example, assessment details may be altered if students are required to undertake a project or task that relates to the local context" (UTAS, 2010). UTAS also provides links to additional documents that can assist lecturers in planning for multi-campus teaching and learning, such as: a) *learning and delivery systems*, a flow chart model that prompts the user to consider the alignment of intended learning outcomes, learning activities and assessment before making decisions about the most appropriate combination of delivery systems; and, b) *delivery systems capability considerations*, a grid that provides an overview of the various delivery system options from face-to-face to web/Internet, print, and multimedia, and the suitability of each for various types of interaction and real-time versus delayed asynchronous communication in lecture, tutorial or seminar contexts.

5. Griffith University has developed a publically accessible web site titled "Program leadership in multi-campus universities." With a clear emphasis on supporting the practice of program leaders through professional development resources, the site features a range of evidence-based strategies and ideas for effective program leadership stemming from an ALTC funded project with partner Institutions University of Western Sydney and La Trobe University. Embedded video clips of program leaders responding to hypothetical questions about improving quality in multi-campus teaching contexts add a degree of authenticity and authoritative voice, at the same time capitalizing on the power of interactive multimedia to engage the viewer at their own pace, scrolling forward and back to replay at their discretion. The amount of MCT-targeted content on this site appears to have grown from the time of the initial web-search for this study (early 2011) to the time of publication.

Common to the five Australian university web sites categorised in Table 1 were resources that enable lecturers to translate general policy and principles concerning flexible delivery into practical strategies for ICT-assisted multi-campus teaching. One that stood out as useful to guide course design and planning for multi-campus delivery was a "learning and delivery decisions" flow chart published online by UTAS (2010) that could, ideally, be used in conjunction with a grid that compares the strengths and weaknesses of different ICT tools for various teaching and learning contexts (e.g. Thomas, R. & Presley n/d). Towards understanding how similar policies and principles are translated into action at the grass roots level, the first of a series of interviews with staff responsible for MCT were conducted at the authors' home institution.

Interviews with staff involved in ICT-assisted multi-campus teaching

In the following summary and discussion of interviews with teaching staff, coded initials representing each participant are used as in-text references to indicate the volume and source of quotes and summary statements.

Almost half of the participants had recently taught courses entirely online to cater to the flexible and/or distance learning needs of their postgraduate student cohort (LB; DE; GL; WJ; BC; BMC; WGM; FG). Some of their students were geographically dispersed parents studying for a graduate qualification part-time while employed full-time. Other categories included undergraduates based at smaller satellite campuses and those based temporarily off campus during practicum or workplace integrated learning placements (GL, GP, SS).

Most participants used the Learning Management System (LMS) Blackboard in keeping with the University's guideline that all courses should have an online presence (described as an 'institutional factor' in Stacey and Gerbic (2008, p.966). Their general approach to course design and facilitation corresponded with Oliver and Herrington's (2001; 2003) description of the online learning experience as a "network of three overlapping elements of a learning design, that is, learning tasks, learning resources and learning supports" (ibid).

The teaching context of two participants stood out as they deliver courses across institutions as well as multiple campuses. Their interaction with students relied primarily on room-based videoconferencing used in conjunction with electronic whiteboards, email, and occasional desktop videoconferencing and telephone calls. The videoconference and electronic whiteboard (Smartboard) technology infrastructure was installed as part of a national initiative to support cross-institutional teaching and learning of mathematics. One lecturer explained that this essentially predetermined their approach to ICT-assisted teaching:

> "Well the [ICT-equipped] room was set up first and the challenge was to use it" (WGM).

While this is not a text-book example of the principle "make learning decisions first" (UTAS, 2010) ahead of choosing the most appropriate delivery system, both lecturers agreed that the videoconference system used in conjunction with Smartboards has been appropriate for teaching of maths in this cross-campus/cross institutional context, especially since it enables synchronous, real-time interactive communication.

> I think that mathematics really is an activity, … you need to actually do it and demonstrate it when teaching – and so that's what I tried to do using the Smart whiteboard. One of the advantages … is that you can save everything as a pdf, and so I saved everything I could and circulated that to the students as well after the classes" (WGM).

The second mathematics lecturer had arrived at similar conclusions about the immediacy of communication enabled by videoconference, and the benefit of being able to save electronic whiteboard presentations for students to view before and after lessons.

> (BMC) The combination of the Smartboard and the video camera facility … were just perfect! … I can talk it through and they [students] can … actually watch me drawing it … so I think that helps reduce the anxiety factor about the maths. … And it's the ability to even interact with the students and ask them questions, you know "well how would you do that?" … So the ability to have them actually participate in the process … while still having prepared materials … that I can put up on Blackboard afterwards, just the combination was fantastic!" (BMC)

Although the literature suggests that room-based videoconferencing is not a panacea for multi-campus delivery (Downey and Brown, 2009; Ebden, 2010) the immediacy afforded by videoconference and electronic whiteboards was clearly valued by these mathematics lecturers as a means to interacting with and engaging students at remote campus locations. The ability to save, distribute and reuse digital resources was also valued by their colleagues in other disciplines (JS; WJ; JC). Combined these practices correspond with a number of established best practice recommendations for blended learning, such as: a) develop shareable and reusable digital resources to ensure that blended learning is sustainable (Littlejohn & Pegler, 2006 in Stacey & Gerbic, 2008); and, b) design courses for "strong integration between the two environments" [face-to-face and online] (Garrison and Vaughan, 2007 cited in Stacey & Gerbic, 2008). It is also significant to note that these lecturers stressed the usefulness of the electronic whiteboard to make the most of the videoconference-mediated teaching. This corresponds with Downey and Brown's (2009) reflection that not being able to simulate an electronic whiteboard contributed to "a lack of interactivity" in a cross campus videoconference-mediated teaching situation they describe (p.220).

Asynchronous discussion via forums on the LMS (Blackboard) discussion board were the primary means of online communication used by most participants. Several staff responsible for teaching smaller groups used synchronous communications technology such as Chat in the Blackboard virtual classroom environment. Two lecturers (LM; NO) were enthusiastic about Chat citing positive feedback from students. One spoke about the social learning aspects of using a 'talking circle' approach in the context of an online indigenous studies course:

> Being an aboriginal studies area, and being indigenous myself, we put a lot of store on the fact that it is a relationship environment and in class you get great opportunity to do that interaction and personalize the delivery. Online was a challenge, Chat was perhaps the best that I could do to try to create that same

classroom environment, and as a whole I think we achieved it. (Lecturer, 'NO').

This example of using Chat successfully to facilitate a learning activity normally conducted in a face to face setting is indicative of an 'equivalent not identical' learning activity (a common principle in multi-campus university policy statements and guidelines (e.g. UTAS, 2010). The lecturer conceded, "it took a little while for the students to warm to it [as] none of the students had been exposed to chat before." However, in terms of achieving intended learning outcomes by a different means the ICT-assisted 'talking circle' approach in real-time (synchronous) was considered a success.

In contrast, several lecturers at a small satellite campus perceived that most of their students prefer 'asynchronous' communication tools largely due to their circumstance as distance learners with professional and personal commitments that are easier to balance with the flexibility afforded by discussion boards and other asynchronous communication tools.

> I got no takers [for Chat] in the time slot. … I guess because they are at a distance from the campus and they've often got other work commitments that preclude them from always being in one spot at one time, so it's about them juggling their commitments so that's why the asynchronous method I think still is more attractive to them (LB).

Summary of Interviews

Interviews with teaching staff helped to identify the variety of ways that multi-campus teaching equity principles are applied at the grass roots level. Not surprisingly, factors such as size and geographic location of students, and the nature of the course being taught influenced decisions about asynchronous versus synchronous online communication tools, course design and facilitation methods. Most significant to note, however, was the evidence of stated course objectives and outcomes being achieved in spite of being taught in different ways across multiple locations. For example, talking circle learning activities and advanced mathematics being taught in a blended mode to some students and fully online (including by videoconference) to others were two such examples.

Conclusion

Results of the literature review revealed a growing body of scholarly literature on the challenges of multi-campus teaching. However, few concrete solutions or comprehensive models to assist decision-making and planning were found in the literature or by following links identified through a search of Australian university web sites. Only a small number of universities appear to have developed publically available resources that treat ICT-assisted multi-campus teaching as a distinct category of flexible learning that is worthy of special attention. This accords with Ebden's observation that "despite the growth of multi-campus teaching, little evidence exists to guide the development of multi-campus course delivery" (2010, p.1). Interviews with teaching staff helped to identify various ways that multi-campus teaching equity principles are applied in practice at the grass roots level. Importantly, these participants were in the habit of critically reflecting on their new innovations and practices, although only a few had formally written up results of systematic evaluations for dissemination among colleagues and scholarship of teaching and learning publications. It is anticipated that more investigating, aggregating and sharing of such information could inform improved guidelines, teaching practice and equity of experience for students at multi-campus institutions.

The iLessonPlan: a lesson planning tool for the 21st century

Alages Andre
School of English
Manukau Institute of Technology

Learning technologies increasingly play a key role in enhancing teaching, learning and assessment. However, it is common practice for English Language trainee teachers to use hard and or soft copies of sample lesson plans presented in a table or list format in the classroom and for feedback. This is the conventional approach used to plan lessons. This approach compounds the complex and complicated process involved in planning ESOL (English to Speakers of Other Languages) lessons. Also the approach does not take advantage of new learning theories and new learning technologies. This paper reports the findings of an ongoing project where a lesson planning tool was designed and developed to replace the conventional approach. This tool, the iLessonPlan, is a prototype interactive online lesson planning tool. In this paper, the design of the iLessonPlan is described, a prototype version is demonstrated and feedback on the use of the tool is presented.

Keywords: interactive lesson planning tool, iLessonPlan, planning ESOL lessons,

Background

Lesson plans serve to ‘provide a means of formalizing learning activities and a framework for teachers to reflect in a deeper and more creative way about how they design and structure activities for different students and help achieve constructive alignment between theory and practice’ (Littlejohn, 2003; Conole & Fill 2005 as cited in Conole, 2007, p. 87).

Although learning technologies increasingly play a key role in enhancing teaching, learning and assessment, it is common practice for ESOL (English to Speakers of Other Languages) teachers to use hard and or soft copies of lesson plan templates presented in written form. This is a conventional approach used to plan lessons. The term ‘lesson plan’ as used in this paper refers to ‘a description or outline of the

‘objectives a teacher has set for a lesson,

activities and procedures the teacher will use to achieve them and the order to be followed, and

materials and resources which will be used’ (Richards, Platt & Platt, 1993, p. 210).’

Statement of problem

Planning an ESOL lesson is a complicated and complex process for ESOL trainee teachers. A typical lesson involves teaching language skills: Reading, Writing, Speaking and Listening and or language features: Grammar, Vocabulary and Pronunciation. Each skill and feature is divided into microskills. In Reading some examples of the microskills are 'Identify main ideas', 'Identify specific information', 'Identify sequence of ideas'. In Grammar, they are 'Use the present simple tense correctly'; 'Use the present continuous tense correctly' etc. In planning the lesson, the trainee has to take into account several factors: background information about their students (age, gender, nationality), their level (PreElementary, Elementary etc), time allocated for the lesson, number of students in a class, the microskill to be taught, aligning learning outcomes with various learning activities, and the resources and equipment for them.

Trainees face several issues in planning lessons as they lack the knowledge required. For example they have problems in identifying and recalling key components in the lesson plan e.g. background class information and especially teaching procedure. Another is in comprehending the lesson structure and flow (from warmer, activities and wrap-up in the teaching procedure) and how it fits together into a well planned lesson. Confusing terms used in the lesson plan e.g. language skills and language features pose another difficulty. Also understanding the concept of learning outcomes linked to the design of learning activities is a real challenge to the trainees.

It is common practice for trainees to make use of hard and or soft copies of sample lesson plans to use in the classroom and for feedback. Sample lesson plans are generally presented in either a table or list format. The former is illustrated in http://www.englishraven.com/files/Lesson_planning_sheet_641321.pdf. A list of 'generally agreed components of a lesson plan' is provided in http://teflbootcamp.com/tefl-skills/tefl-lesson-planning/

Trainees can use either format and after completing the information required, they submit the plan

to their tutors for feedback. Based on the feedback, the lesson plan is revised and then delivered. After delivery trainees complete their reflection of the lesson. This is the conventional approach used to plan lessons. This approach compounds the complex and complicated process involved in planning ESOL lessons as discussed above. Also the approach has inherent limitations in that it is not interactive, intuitive or user friendly.

Planning lessons is a time consuming process as it involves accessing and assembling hard and soft copies of materials and resources required from different locations e.g. resource centers and online repositories. Moreover materials are available in different formats e.g. audio and video files, images etc. Time and effort spent in accessing, collecting and assembling materials from different locations also impacts on planning a lesson. Using the conventional approach to planning lessons does not in any way make this process easier.

The iLessonPlan

To address the issues, the iLessonPlan (iLP) tool was designed and developed to provide an approach to lesson planning to replace the conventional approach. The iLP is a prototype interactive online lesson planning tool. The iLP was created to be intuitive, trainee friendly and capable of running online or offline via a standalone browser. The tool designed with an inbuilt lesson plan template captures the process of planning a typical ESOL lesson in an explicit and well organized manner.

Purpose of the iLP

The purpose of the tool was to help trainees understand the process of planning a typical ESOL lesson. Trainees here
refer to ESOL trainee teachers enrolled in an ESOL Certificate Programme in New Zealand. The tool has an inbuilt lesson plan template which assists them to complete a lesson plan. It also gives the trainee an interactive soft copy of the lesson plan.

Using the tool would enable the trainees to:

1. Develop their knowledge of lesson planning by:
   i. Identifying and recalling key components in a lesson plan.
   ii. Following the structure and flow of the lesson plan
   iii. Getting just in time help with difficult terms used in the lesson plan.
   iv. Using learning outcomes as a basis to design learning activities.

2. Plan and prepare their lesson plans more effectively and efficiently by:
   i. Using a tool that is intuitive and trainee friendly.
   ii. Engaging with a tool that promotes active learning and interaction
   iii. Using a tool that provides an authentic learning experience
   iv. Reducing the time, cost and effort spent in planning lessons.

The iLP: an overview

The tool facilitates the process of planning a lesson. The tool is a vehicle for the lesson plan itself as the template is embedded in the tool. In producing an interactive lesson plan, it is ready for feedback and ultimate use.

The tool is composed of Parts 1-6 as seen below and in Screenshot 1. The key components of a lesson plan are found in Part 2: Class Info (Screenshot 2) and Part 3: Teaching Plan.

Parts of the iLessonPlan tool

Part 1: Intro provides an overview of the iLP

Part 2: Class Info identifies

1. Class level
2. Time allocated
3. Student profile – number of students, students' ages, gender and nationality.

Part 3: Teaching Plan includes

1. Main teaching point
2. Learning outcomes
3. Resources and Equipment
4. Teaching procedure
   i. Warmer
   ii. Activity 1, Activity 2
   iii. Wrap-up

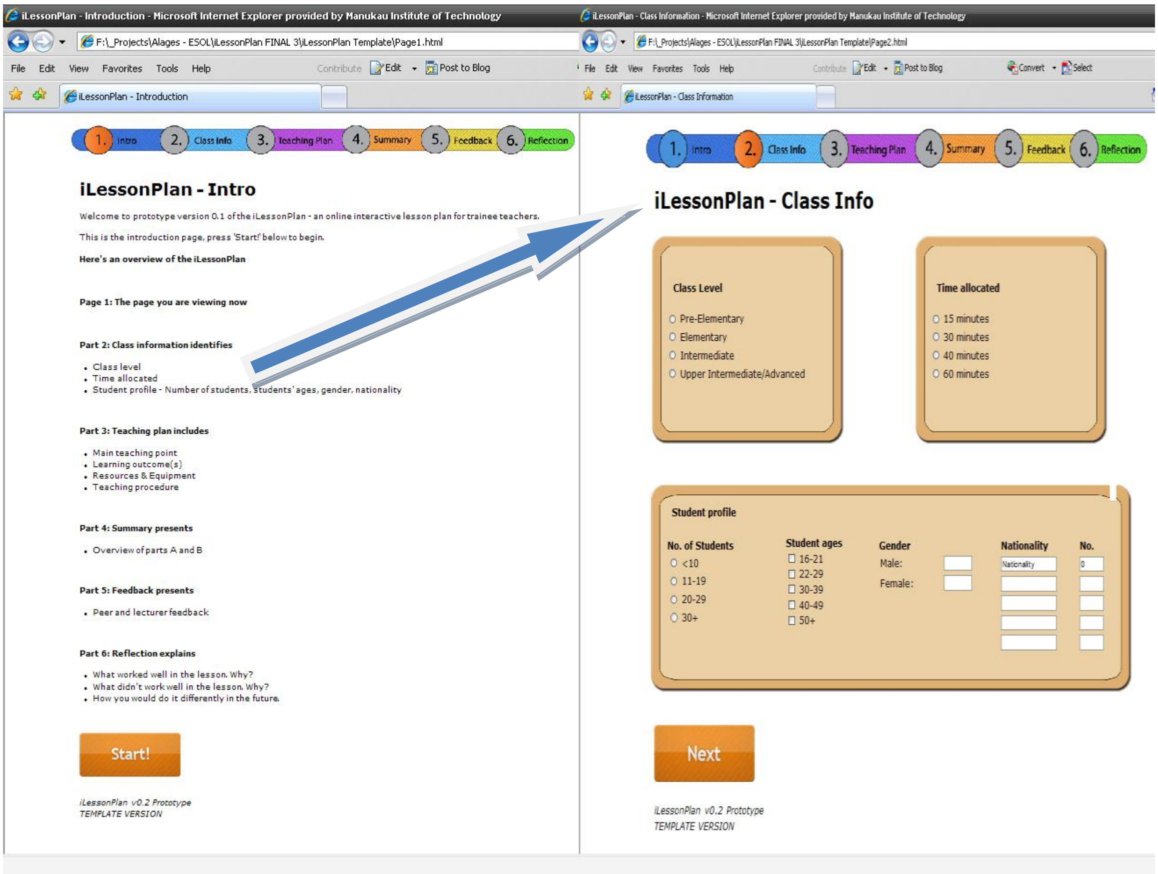
Part 4: Summary – should read Lesson plan as it comprises Part 2 and 3 and it can be printed and kept for future reference.

Part 5: Feedback presents Peer and Lecturer Feedback

Part 6: Reflection explains

i. What worked well in the lesson and why?
ii. What did not work well in the lesson and why?
iii. How would you do it differently in the future?

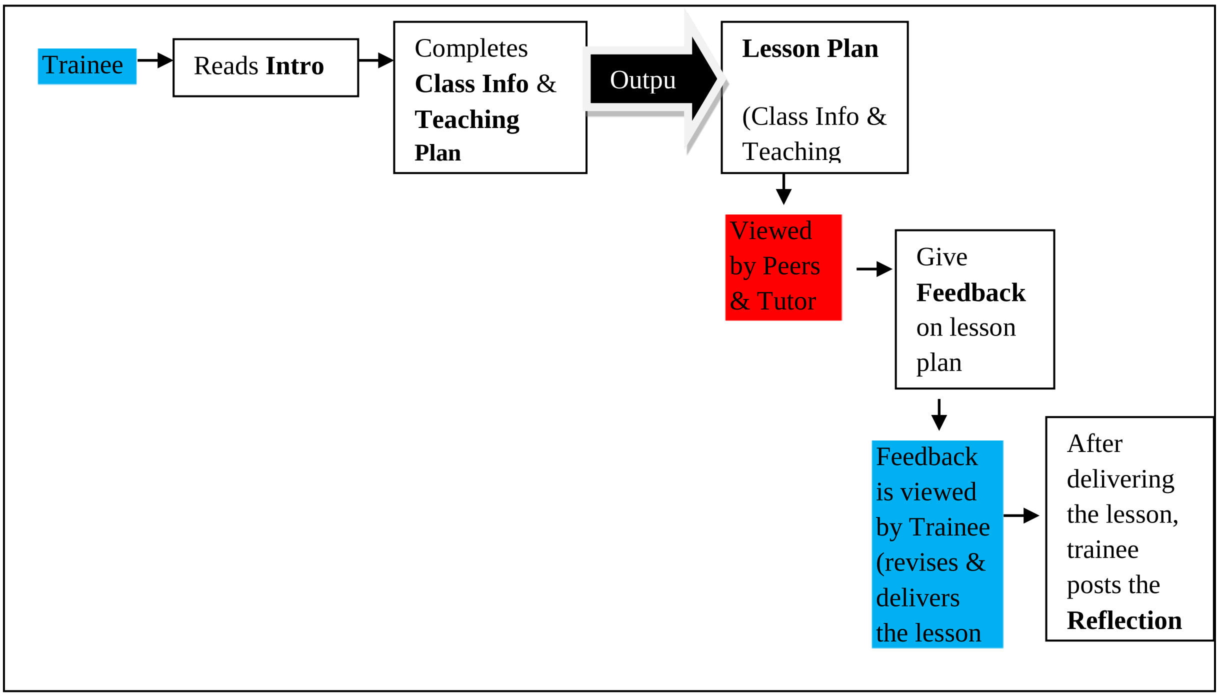
Screenshot 1: iLP-Intro p.1 **Screenshot 2: iLP-Class Info p.2**



Using the iLP

An overview indicating how the tool is to be used is presented in the flowchart below. The three users of the iLP are the trainee, his/her peers and tutor. The process starts when the trainee reads Part 1: Intro to get an overview of all the parts in the tool. Then he/she clicks START which takes him /her to Part 2: Class Info (inbuilt lesson plan template). After filling in the information required about his/her class, the trainee clicks NEXT to Part 3: Teaching

Using the iLP: the process



Plan (inbuilt lesson plan template) and completes the template following the instructions given. Next he/she clicks SUBMIT and the OUTPUT is Part 4: Summary (to read Lesson plan in the next phase of the iLP development). The lesson plan comprises information in Part 2 and 3 which can be printed or saved as a file for future use. If the trainee omits some information then a popup window will appear indicating that some fields have not been completed in. When all the information has been completed then the trainee is able to submit the lesson plan (The iLP is stored in a remote server where the trainee gets access to it when he/she is logged in).

At this point the peer and tutor view Part 4: Lesson Plan and click NEXT. This takes them to Part 5: Feedback which they complete. Then they click NEXT. (Now the plan is stored on the remote server (web server). The trainee can download a version of the plan to keep it locally if he/she wishes).

The trainee views the feedback and then revises the lesson before delivering it to a class. After delivery the trainee posts his/her reflection. (At this point, the iLP is stored on the remote server permanently (unless the trainee wishes to delete it). Peers can view and submit the plan (but not edit it). They can also submit comments or feedback which is also kept on the remote server. These may be moderated or disabled by the trainee who submitted the plan).

Discussion of the iLP

The iLP comprises six parts which are described below:

Part 1: Intro

Part 2: Class Info

Part 3: Teaching Plan

Part 4: Summary

Part 5: Feedback

Part 6: Reflection

Part 1: Intro provides an overview of the six parts in the iLP. The aim is to give a broad description of the iLP, what trainees can expect to see and how it works. (Refer to Screenshot 1: iLP-Introduction p.1).

Part 2: Class info comprises the following elements as illustrated in iLP. (Refer to Screenshot 2: iLP-Class Info p. 2).

1. Class level is one of many factors that need to be considered when planning a lesson as it significantly affects selection of learning outcomes, resources used and the teaching procedure.
2. Students are grouped into classes based on their levels: Pre-Elementary, Elementary, Intermediate, Upper Intermediate and Advanced. Descriptors for each level are provided for the four language skills: reading, writing, listening and speaking. One example for reading is Pre-Elementary where a student is described as having 'little ability to read English' and is 'able to match isolated words to picture prompts' (Descriptors used at the selected tertiary institution). This information is crucial for trainee ESOL teachers as it impacts on selection of relevant materials and resources to use.
3. Time allocated for the lesson is another important consideration as this helps trainees plan the number and type of activities that can be completed within the time frame given: 15, 30, 40 and 60 minutes.
4. Student profile includes information about student numbers, students' ages, gender and nationality. Establishing student numbers helps trainees prepare the required number of handouts, and plan suitable activities. Also student numbers can be used to plan how students work on activities: individually, in pairs, groups or the class as a whole. Adequate provision can also be made in terms of furniture and equipment e.g. chairs and tables, computers, headsets etc. Having knowledge of the approximate age group of students, gender and nationality is useful in enabling trainees identify potential topics of interest, their students' cultural background and learning styles.

Part 3: Teaching Plan comprises four key elements: Main teaching point; Learning outcome; Resources; and Teaching procedure. Content is made accessible to the trainees in two ways so that they can 'progress from teacher directed activity to self-regulated activity' (McLoughlin 2002:149). One is by deconstructing terms using explanations and examples. Another is by clarifying instructions given in the rubric using key questions.

Scaffolding is provided in terms of task support when suitable. According to McLoughlin (2002:149),

> Designing scaffolds for learning involves conceptualizing new roles for learners and teachers in fostering task engagement, social interaction and peer feedback … support must be designed in a principled way in order to ensure that learners progress from teacher-directed activity to self-regulated activity.

Using scaffolding also illustrates the associative approach to learning where concepts are built 'step by step' (Beetham & Sharpe, 2007, p. 221). The key elements in the Teaching Plan are explained below:

1. Main teaching point refers to language skills and language features. The former refers to reading, writing, listening and speaking and the latter to grammar, vocabulary and pronunciation. Each language skill and feature is subdivided into microskills which are accessible using the dropdown menu. When trainees mouse over language skills, the dropdown box lists the four language skills and when each of these skills is moused over, the microskills appear.

   In moving the cursor over reading, the microskills listed are 'Identify main ideas', 'Identify specific information' and 'Identify sequence of ideas'. When the trainees mouse over writing, a dropdown box lists the microskills e.g. 'Begin every sentence with a capital letter. End every sentence with a full stop'. (It is important to note that NOT ALL microskills are listed as the iLP was designed to be a prototype). The advantage provided by the drop-down menu boxes is an example of task support which is one of the 'core elements of support for the learning process in environments mediated by technology' (McLoughlin &

Oliver, 1998 as cited in McLoughlin, 2002, p. 4). The design feature facilitates quick and easy selection of items and clarifies the terms used by providing examples.

2. Learning outcome/s specify what students will be able to do after the lesson. Task support is provided in the rubric in each element: explanations of the instructions and examples of answers clarify to trainees what is required. The outcome/s relate to the microskills selected by the trainees under language skills and features.
3. Resources include materials used in the lesson which are subdivided into physical and digital resources. The former refers to hard copies of text: brochures, schedules, newspaper articles etc and the latter to websites, media, images, sound files etc. Digital file upload is a design feature to facilitate the lodging of files such as scanned copies of reading and listening comprehension questions, audio and video clips on a server. Equipment includes items, tools or other objects used in the lesson: computers, document cameras, whiteboards, markers, etc. Utilizing the digital file upload feature has several benefits. One is that it is a time saving tool as files can be uploaded quickly. Another is that it saves cost making copies of CDs for sound files and DVDs for video files. It is also friendlier to the environment as it reduces the amount of paper used. Storage and retrieval of files is also a plus point as it is just a click away.
4. Teaching procedure describes the four steps involved in teaching a lesson.

   i. Warmer introduces the topic to students in a fun and engaging way. The purpose is to interest students in what they are about to learn in the lesson.

   ii. Activity 1 is a task that relates to the learning outcome. The term 'task' refers to 'an activity which is designed to help achieve a particular learning goal' (Richards, Platt, & Platt, 1992, p. 373). The learning goal or the learning outcome/s is / are established with reference to the language skills or language features selected. Retrospectively, the term 'task' should be used instead of 'activity' as it is a more accurate description of what is involved in planning a lesson.

   iii. Activity 2 is the same as in (ii).

   iv. Wrap-up summarizes the lesson, or assesses what students have learnt.

Part 4: Summary presents an overview of Parts 1 and 2. It was designed to be viewed by other trainees so that they can post feedback on the lesson plan in Part 5 Feedback.

Part 5: Feedback includes peer and lecturer feedback. The importance of feedback is supported by all three learning approaches. Feedback facilitates learning 'whether that feedback comes from within, a teacher, or a peer. When provided the opportunity for revision, students can achieve at higher levels and reach deeper understandings' (Driscoll, 2002).

Part 6: Reflection describes the trainee's reflection on the lesson conducted. This involves looking 'back on teaching, calling some aspect of it into question, analyzing it, evaluating it and making plans for improvement' (Cook, 1998, p. 1). Reflection is essential to improving one's practice as a teacher. This is supported by the situative approach to learning where 'People learn by participating in communities of practice, progressing from novice to expert through observation, reflection …' (Beetham & Sharpe, 2007, p. 221). Reflection is also considered a critical activity in the constructive (individual) and constructive (social) approaches to learning.

Design of the iLP: Criteria used

The design and development underpinning the iLP is based on learning theories and applied research in elearning. The criteria and rationale used in the design are explained below.

1. Building concepts and competences step by step facilitates learning

In the iLP, the process of planning a lesson was deconstructed into six parts. Each part was further segmented and in some cases sub-segmented to make it simpler and easier for trainees to understand key components and important stages in planning a lesson. This is based on the associative approach where learning is understood as 'building concepts or competences step by step' (Beetham & Sharpe, 2007, p. 221). Two examples are provided: Part 2: Class Info and Part 3: Teaching Plan. The former includes: Class level, Time allocated and Student profile – number of students, students' ages, gender and nationality. The former comprises: Main teaching point, Learning outcomes, Resources and Equipment and Teaching procedure – Warmer, Activity 1, Activity 2 and Wrap-up.

2. ***Sequencing and structuring information in a learning workflow promotes effective learning***

The rationale is that there is a logical progression of content from general to specific which students can relate to. This strategy is used consistently in the design of the iLP. For example providing an overview of the iLP: Part 1 Introduction helps trainees anticipate what they are about to read and gives them a logical framework to follow the progression of the lesson from start to finish. (Refer to Screenshot 1: iLP-Introduction p.1).

3. ***Active learning and interaction engages learners more effectively***

The concept 'active learning' refers to learners as 'active participants in the knowledge construction process' ... and 'using technology tools "to think with" facilitates working with ideas and learning from that process (Scardamalia, 2002 as cited in Driscoll, 2002). Technology tools provide "the means through which individuals engage and manipulate both resources and their own ideas" (Hannafin, Land, & Oliver, 1999, p. 128 as cited in Driscoll, 2002). In using the iLP, trainees are required to plan their lesson taking into account: class level, time allocated and details of student profile. The considerations inform their decisions on type and difficulty of teaching materials, type of resources, design of learning activities etc. The 'technology tools' mentioned above are exemplified in the interactive trainee interface: navigation buttons, drop down menu boxes, text boxes etc.

Encouraging active learning can be implemented by designing activities which require learners to share and debate ideas, give and respond to peer feedback, reflect on the tasks and activities etc. Chickering & Gamson (1987) highlight 'Encouraging active learning' as one of the seven principles for best practices in undergraduate education. Trainees are required to provide feedback on their peers' lesson plan and complete their reflection of the lesson after it has been conducted.

Not only do learning activities promote active learning, they also enhance interaction as it is considered a 'key value proposition' in 'technology mediated learning'. It is perceived as 'the defining attribute for quality and value in online learning experience' Wagner (2006: 44). The term 'interaction' has several definitions depending on the context of use. The term 'instructional interaction' in Cowley et al (2002) is used here as it relates to a pedagogical context. The term refers to:

… an event that takes place between a learner and the learner's environment. Its purpose is to respond to the learner in a way intended to change his or her behavior toward an educational goal. Instructional interactions have two purposes: to change learners and to move them toward achieving their goals (Wagner 1994).

Incorporating interaction in learning activities keeps learners engaged and motivated. Activities that foster interaction provide opportunities for dialogue and feedback between learners, peers, and others (instructors and the world at large). The importance of feedback is supported by the three approaches to elearning theories: the associative '(building component skills into extended performance)', constructive '(integrating skills and knowledge, planning and reflecting)', and situative approach '(developing identities and roles)' (Beetham, 2007, p. 27). Feedback informs learners of their progress and stimulates them to reflect on areas for future progress (Chickering & Gamson, 1987).

These activities also encourage consolidation and integration of knowledge, skills and performance. Providing 'interactive environments … and opportunities for reflection' is supported by the constructive (individual) learning approach. Arranging the use of 'collaborative environments' and giving learners 'opportunities for discussion and reflection' is based on the constructive (social) approach (Beetham & Sharpe, 2007, p. 222). In the iLP, trainees interact with content when they use hyperlinks to access multimedia resources and drop-down menu boxes for explanations of terms used e.g. language skills and features. Interaction with instructors and peers is seen in the feedback given to trainees in Part 5 Feedback which includes 'Peer and Lecturer feedback'. (Screenshot 1: iLP-Introduction p.1). Also interaction can be seen when trainees are able to redo their lesson plan (Part 2 and 3) and submit it for feedback.

4. *Authentic learning activities engage learners readily and meaningfully*

'Authentic activities are real-world tasks that a person can expect to encounter on the job, in the home, or in other social contexts (Newmann & Wehlage, 1993, p. 72-75 as cited in Woo, Herrington, Agostinho & Reeves, 2007). As these activities are directly related to students' real-life experiences, they see the relevance between what is being taught and what they are required to do in a real life task. Consequently they engage with the tasks much more readily and meaningfully.

Ten key characteristics of authentic activities were identified by Herrington, Oliver, & Reeves, 2003; 2006, p. 5-6). Of these four are linked directly to the iLP.

i. 'Authentic tasks have real-world relevance.' The iLP can be used by teacher trainees not only during the course of their training but also when they start their teaching. Key elements in the lesson and the logical order and sequence in which they are presented match those used in the classroom. Including authentic tasks and activities is based on the situative approach to learning as they help develop practice in work place communities. Also it contributes to developing their identities in the roles they will soon embrace in the work place.
ii. 'Authentic tasks comprise complex activities to be investigated by students over a sustained period of time.' For trainees, preparing and planning a lesson is a challenging and time consuming task. Selecting and creating suitable and relevant learning activities, considering the level of the students, their prior knowledge, their learning styles and topics of interest, to achieve stipulated learning outcomes is a skill that improves with time and practice.
iii. 'Authentic tasks provide the opportunity to collaborate.' This encourages interaction which in turn engages students more effectively in their learning (Merriam & Caffarella, 1999). Interaction which includes interaction with content, instructors and peers features highly in the iLP. Collaborative work is typical of social constructive approaches' (Beetham & Sharpe, 2007, p. 221) to learning.
iv. 'Authentic tasks provide the opportunity to reflect.' Reflection, which ties in with the social individual and constructive learning approach, is essential in improving future performance. 'Students who analyze and reflect on their learning are more effective learners; that is, they are more able to acquire, retain, and apply new information and skills' http://www.nclrc.org/sailing/chapter2.html Thinking through the lesson and identifying what worked well and what didn't provides valuable input for future lessons. This is the rationale for including Part 6 Reflection in the iLP.

iv. An interactive trainee interface enhances learning from multimedia

'An interactive trainee interface appears to have a significant positive effect on learning from multimedia' (e.g., Bosco, 1986; Fletcher, 1989, 1990; Stafford, 1990; Verano, 1987) as cited in Najjar (1998). He explains that 'An interactive trainee interface may allow learners to control, manipulate, and explore the material or periodically asks learners to answer questions that integrate the material.' This design principle is strongly supported by a variety of studies. See Najjar (1998) for details.

The interactive trainee interface in the iLP comprises design features and functions as listed below:

i. Navigation buttons facilitate easy and seamless movement between sections and pages. On top of each page are menu options: 1. Intro, 2. Class Info, 3. Teaching Plan etc which also function as navigation buttons. Navigation buttons are also present at the end of each page: Start on Page 1 Introduction; Next on Page 2; Submit on Page 3 etc to enable easy movement between pages and sections. (Screenshot 1: iLP-Introduction p.1).
ii. Sub-menus provide a planning pathway for selection of resources and materials in relation to class levels, time allocation, and student profile. (Screenshot 2: iLP-Class Info p. 2).
iii. Drop-down menu boxes enable quick selection of items and provide task support to trainees e.g. definitions and or explanations of terms and concepts used.
iv. Hyperlinks expedite access to multimedia resources: websites, images, podcasts, video clips etc.
v. Text boxes record responses to instructions given: 'Describe the teaching plan', 'Provide feedback' etc.
vi. File attachments enable quick and easy upload of digital files: scanned copies of text and or images, audio and video files etc.

5. *Rules for good design enhance usability of the iLP*

i. Utilizing a colour scheme to enhance readability. White background with black text was chosen to create a better contrast and highlight and to increase the readability of the text. Bright colours for the navigation buttons on top of the page made them distinct against the white background. The colour scheme was repeated on each page for consistency. The overall effect aimed for was an uncluttered slate to make it visually appealing.
ii. Using panels to chunk information enables information to be chunked graphically thereby making it reader friendly. In Part 2: Class Information, there are three panels: Class level, Time Allocated and Student Profile. In Part 3: Teaching Plan there are four panels: Main Teaching Point, Learning Outcome, Resources and Teaching Procedure. Each panel is further segmented into sub-sections e.g. Teaching Procedure is subdivided into Warmer, Activity 1, Activity 2 and Wrap-up.
iii. Presenting overviews of the content is an effective means of presenting information which helps trainees anticipate what they are about to read and therefore make more sense of the information (Part 1: Introduction - iLP Template and Sample). These elements also facilitate scanning which saves trainees time in reading the text (Morkes & Nielsen 1997). The overview also provides a framework for the sequential progression of the components into a structured work-flow.
iv. Highlighting headings, subheadings and key points makes them prominent and distinguishes them from the rest of the text. Bulleting (e.g. Part 1: Introduction and Part 3: Teaching Plan in iLP Template and Sample) and numbering points (e.g. Part 3: Teaching Plan in iLP Sample) enhance scanning.
v. Writing concisely. Short phrases and sentences ranging between 2-17 words per sentence were used in the iLP Template and Sample.

6. ***Using the iLP reduces time, cost and effort in planning lessons.***

Hosting the iLP on the internet provides several advantages which are not possible utilizing the conventional approach.

i. Trainees have quick and easy access to a wealth of materials in different formats (text, audio and video files, images etc) and resources (search engines, websites, social networks, portals, forums, libraries, dictionaries etc) which they can use to plan their lessons. Providing materials in different mediums caters to their students' diverse learning styles (Chickering and Gamson 1987; Kilby 2009; http://www.fgcu.edu/onlinedesign/designDevc.html). Also 'Information presented in more than one medium is recalled better by learners.' (Beetham and Sharpe 2007:226).

i. Accessing materials and resources online reduces time, cost and effort compared to accessing them in different physical locations.
ii. The web provides the means for trainees to store, retrieve, share and replicate iLPs for future use.
iii. The iLP would be available 24/7 and can be translated into any language using Google translation.

Testing the iLP

It is important to note that the iLP is a work in progress. At this stage of development it is a prototype lesson planning tool and it was trialed with only a small group of trainees to show proof of concept. As facilities for proper html testing were unavailable, nine trainees used a pen and paper version of the iLP out of which one third provided feedback. Also due to the small sample size, it was decided to collect qualitative data to identify the trainees' response to using the iLP. They were asked to answer three questions:

1. Did you find the iLP useful in planning your lesson? Why / Why not?
2. What do you think are the advantages of the iLP?
3. What do you think are the limitations of the iLP?

Two of the respondents found that the iLP helped them to plan their lesson in terms of providing a good structure whereas one did not find it useful. Their feedback is as follows:

Feedback 1**:** 'I found the iLessonPlan useful in the way it helped me structure my lesson, step by step. It clearly outlines the exact requirements needed to plan a lesson'.

Feedback 2: 'It's easy to identify the requirements applicable to your lesson plan, has good structure and would only require minimal training if any but this would be dependent on the trainee'.

Feedback 3: '… would much prefer to be given a copy of info/plans etc … didn't find ilesson plan useful in planning because it never crossed my mind to use it'.

Feedback on the iLP was also collected from 2 ESOL lecturers and an ESOL teacher. Their feedback was based on

my presentation of the iLP, 'Design and use of an iLP' at the 'Community for Languages and English for Speakers of Other Languages 2010 Conference'. As the feedback was given verbally it is summarized below.

A senior lecturer from a NZ tertiary institution that coordinates the Graduate Certificate and Diploma in TESOL said, 'Why wasn't this done five years ago? It seems logical to put a lesson plan online'. Another who had taught the CELTA (Certificate in English Language Teaching to Adults) programme identified with the problems faced by ESOL trainee teachers and said the iLP is 'a good tool to use as it addresses the problems trainees face in planning a lesson'. The ESOL teacher mentioned how easy it would have been to plan a lesson if the iLP had been available to her when she did her teacher training two years ago.

It is acknowledged that the feedback on the use of the iLP has been collected from a small sample size. Generally the feedback has been positive however, further in-depth evaluation needs to be conducted using a bigger sample.

Conclusion

The iLP has considerable potential as the design, creation, use and trialing of the iLP indicate that the tool is proof of concept and is worthy of further development. Proper testing of the tool was not able to be done due to the unavailability of the facilities required. This will be addressed in the next phase of development where a website will be developed to host the iLP. Additionally, a formal evaluation of the tool will be conducted and the outcomes will be utilized to further develop and refine the tool.

Collaboration, community, identity: Engaged e-learning and e-teaching in an online writing course

Martin Andrew
Faculty of Higher Education
Swinburne University of Technology

Josie Arnold
Faculty of Higher Education
Swinburne University of Technology

This paper presents a narrative enquiry of the use of learning technologies and communities of practice (Wenger, 1998) in creating and delivering the online Master of Arts (Writing) at Swinburne University of Technology. We consider the research question of how we have come to understand and practice elements of a social constructivist pedagogy involving engaged, learner-centred peer and community support both as a creative team and as e-moderators. We consider, too, that our pedagogy is informed by poststructural understandings of learner identities as invested and unfixed (Weedon, 1997). This study utilizes the self as data by drawing on narratives of course developers and lecturers collaborating to create unique materials. While our methodology utilises elements of autoethonography (Chang, 2008), it also involves analyzing themes and narrative configurations in stories (Polkinghorne, 1995), specifically those of tutors and students. Our narrative exemplifies and proposes strategies for writing e-curriculum for web 2.0; for scaffolding e-learning, and for creating and maintaining communities of invested, engaged learners. Simultaneously we add nuances to the scholarly conversation about e-learning communities, e-curriculum development and subjective academic narrative methodology.

Key words – creative writing, e-curriculum, communities of practice, learner identity

1. Introducing our story

This paper relates the ongoing story of the use of learning technologies in creating and delivering the online Master of Arts (Writing) at Swinburne University of Technology (SUT). Ours is a story spanning a decade, questioning how we have come to understand and practice elements of a social constructivist pedagogy involving learner-centred peer support and engaging learners within communities of practice. Broadly, what have we learned that we can share with providers of online learning? More specifically, how have our experiences of such teaching interventions as building and maintaining online communities of learners and fostering ‘critical friendships’ impacted on the student experience of studying Writing online and the tutor experience of e-moderating? The themes of our enquiry, collaboration, community and identity, serve to structure our story. Our story is itself formally and methodologically a narrative enquiry, a subjective academic narrative. Like Polkinghorne (1998), we hold that narratives contain, or even *are*, people's identities.

Since 2002, this postgraduate course has provided a virtual learning environment through the Learning Management System (LMS) Blackboard. Its pedagogical position utilises people, print and electronic technologies to engage students through virtual lectures, dedicated websites, hyperlinked selected readings and dynamic e-tutorials. This engagement comes in part from creating interventions linking program materials to the writing practice of individual, developing writers, and partly from encouraging sense of community, 'a feeling that members have of belonging, a feeling that members matter to one another and to the group, and a shared faith that learners' needs will be met through their commitment to be together' (McMillan & Chavis, 1986, p.9) through collaborative and authentic practices that build partnerships and community allegiances between and among participants.

Collaboration in communities is a key pedagogical intervention, but for writers there is also the question of the individual invested in her or his writing, creativity and applied learning. This paper, to some extent, examines how we use online communities to reconcile the collective and the individual. Since all of our participants strongly desire to identify as writers and to belong professionally to groups attended by writers, we conceive of their desires to be, to become and to belong in terms of desire to align with 'imagined communities' (Anderson, 1983). Yasuko Kanno and Bonnie Norton (2003) believe Anderson's analogy of nationhood and community helps those who want to belong feel a sense of community with people not yet met. In applying Anderson's concept, we envisage a culture's sense of community as an imagined space. We view individuals as idealising community and creating a sense of self through these imaginings. Students of writing want to belong to the elite group labelled 'writers' and to associated communities; but they also want to develop their own voices. There are, as in Jean Lave and Etienne Wenger's (1991) formulations, connections between imagined community and desired identity. The MA draws on this insight in its application of the collaborative pedagogical intervention of critical friendship and in understanding learners' desires for a future self as a writer impacts learner investment (Andrew, 2009).

The core unit of year 1 study 'Critical Friends' acculturates our students to learning in communities of practice (CoPs), establishing the behaviours that characterise their support of others' learning throughout the program. 'Critical friendship' refers to an organised, mutual, reciprocal exchange of ideas and work for the purposes of improving submissions before they are posted to tutors. The concept used *the collective* – the community of practice – as a vehicle for addressing the *individual*. Critical friendship involves giving and receiving feedback at both mechanical-discursive and critical-analytic levels. At various stages, the technique is used with the aid of both criterion-based guides to giving critically friendly feedback and, prior to submission, guides to editing. Critical friendships are forged early in the 13-week course between sympathetic participants within online discussion forums, are mediated by tutors and may last for the duration of the program and beyond.

The evolving story of the MA (Writing) emphasises the interconnected themes of collaboration, community and identity in relation to both our e-curriculum and e-learning designs and our teaching/delivery. For Rena M. Palloff and Keith Platt (2005), collaboration is the 'cornerstone' of e-learning and the grounding of e-community (p.xi), accomplishing such outcomes as addressing all learning styles and cultures, assisting with deeper knowledge generation, promoting creativity and initiative and allowing shared goals for the foundation of a learning community (pp.6-7). Social constructivism, informed by both Vygotskian and sociocognitive theories of learning, foregrounds the centrality of engaged learning communities mediated through the LMS, particularly the discussion and chat facilities (LaPointe & Reisetter, 2008). In their study of postgraduate students' 'sense of community online', LaPointe & Reisetter point to the importance of 'belonging'. This suggests both the need for an articulated and *heard* voice in the e-community and a desire for identification with other imagined communities beyond the immediate e-environment. In this context, we recognise identity for writing students is more than 'social presence' as involving the salient person we become online and how we express that persona (Gunawardena & Zittle, 1997; Kear, 2010). Our experience indicates that the identities involved in creating and participating in e-environments in writing are, like poststructuralist identities Weedon

(1997) describes, complex, affected by power, desire and discourse and subject to change. Bourdieu (1986) would consider them 'invested' identities, beyond the dualities of extrinsic and intrinsic or instrumental and integrative motivation, but rather integrated towards creating and developing authentic writerly identities, the cultural capital of writing programs (Ivanic, 1997).

While the themes of collaboration, community and identity apply to our learners – largely working professionals seeking to develop their creativity and/or a career tree-change – our story also tells of how the still-evolving program develops from *carpe diem* style collaborations among lecturers, learning designers and ITS specialists (Armellini & Jones, 2008; Salmon, Jones & Armellini, 2008); how our ongoing curriculum development and e-learning design are impacted by insights from the social constructivist concept of CoP (Brown & Duguid, 2000; Jonassen, Peck, & Wilson, 1999; Lave & Wenger, 1991; Wenger, 1998), and how we recognise the individual pedagogical contributions of members of the lecturing team as contributing to well-mapped subjects within a clearly structured program comprising 12 subjects across 3 levels.

Beyond the core team of lecturers, we involve the wider teaching team - including specialist guest lecturers and sessional tutors - in the design-redesign action research cycle that informs our teaching and learning practices. These people have writing identities and links to industry. The curriculum gives them as well as the tenured lecturers and their specialist discourse audiovisual presence in our program. The concepts of *mutual engagement, joint enterprise* and *shared repertoire* (Wenger, 1998) – and the sharing of this repertoire – are central to both the development and reconstruction of e-learning environments and the facilitation of collaborative learning spaces in the LMS. The sharing of lecturer, tutor and learner discourse informs sections 4 and 5 of this paper, where we relate designer, lecturer, tutor and participant experiences of teaching and learning in our e-environment.

An increasing body of research investigates the impact of socialisation and collaboration in CoPs on learner identity in cyberspace (Brook & Oliver, 2003; Haythornthwaite, Kazmer, Robins & Shoemaker, 2000; Jones & Peachey, 2005; Kreijns, Kirschner & Jochems, 2003; Rovai, 2002). Socialisation is, of course, Gilly Salmon's crucial second stage in her five-stage model of teaching and learning online (2003; 2004), emphasising a mixture of constructivist learning design and strategic e-moderating bringing forward 'imaginative and creative images' (2004, p.34) as two keys. Palloff and Platt (2005, 2007) led the way in strategising the scaffolding of e-learning to maximise sense of community while similarly promoting creativity and critical thinking. In our narrative, this strategising has shown itself as most significant for the students' learning journeys.

Fundamentally, engaged students need to be both *responsive* and *involved* to enable community building (Palloff & Platt, 2007, p.72). In such communities, constructivist learning is 'active, constructive, intentional and cooperative' (Jonassen et al., 1999). Brown and Duguid (2000) established three principles for learning in communities; it is: *demand-driven, a social act* and *an act of identity formation*. In our narrative of the MA (Writing), we view learning as collaboration yet we focus on each individual constructing their identity within the social space of the learning group. As a result, people have shared visions and identities in common: 'People, forming a community, come together because they are able to identify with something – a need, a common shared goal and identity' (Hung & Der-Thanq, 2001, p.3). 'In an e-learning community', Tu and Corry (2002) advise, 'members work together to solve their problems and to improve their communities using knowledge construction media and technology' (p.209). Our fundamental subject 'Critical Friends' informs this throughout the MA (Writing).

Studies also suggest that the resulting imagining of participation in future communities can be an even more powerful spur to students' investment (Kanno & Norton, 2003). Students' imagined communities can be better realised by understanding learners' desired selves (Markus & Nurius, 1986). Hazel Markus and Paula Nurius emphasise that learners might possess conceptions of possible selves that differ from their current actual self; this certainly applies to our writers. The sharing of discourse and repertoire in our e-learning environment helps learners describe their desires and ambitions, and to see themselves both as developing individual voices and as members of imagined communities, starting with their online tutorial group and developing with their development of critical friendships facilitated and mediated by the e-environment. For many, imagined communities are sites of publication, virtual or real, places of desire for belonging.

2. The story of our methodology

This is our story about how we practice autoethnography and subjective academic narrative enquiry in both making and reflecting upon our e-learning and e-teaching curricula and delivery. Such academic narrative non-fiction is a research method academics apply in their writing to demonstrate that autobiographical experiences can be analysed and interpreted in their research so as to unpeel and unpack their cultural assumptions (Chang, 2008, p.9).

Arising from and embedded in our unique curricula pedagogy, this methodological prism recognises the impossibility of seeing ourselves as academics as either independent or unaligned. We come from a cultural discourse and we participate in that discourse. Our storytelling recognises this and provides a space in which we can understand acting against the 'given' or cultural meta-narratives that have dominated so much of academic discourse. We recognise that we are enabled by critiquing perspectives that lead us to undertake research in an area and/or pursue a certain line of investigation and research question because of our Eurowestern understandings, particularly those of the Enlightenment.

The self-narrative in autoethnography leads to and involves the analysis of storytelling and enquiry into self and others as data rather than mere presentation of story. Autoethnography takes self-narrative from the arena of storytelling into that of the production of data leading to new knowledge and/or new understanding of areas of known knowledge. Stemming from anthropology, autoethnography 'transcends mere narration of self to engage in cultural analysis and interpretation' (Chang, 2008, p.43). Unpeeling and unpacking the self and the ways in which it produces data through interactions, observations, analyses and interpretations provides us with insights into the modes of thought, action and interaction that underpin and/or evolve from enacting the self and others as data. For Carolyn Ellis and Art Bochner (2000), this provides 'autobiographies that self-consciously explore the interplay of the introspective, personally engaged self with cultural descriptions mediated through language, history and ethnographic explanation' (p.742).

While our study is methodologically an autoethnographic subjective academic narrative, we also draw on and analyse qualitative data from our nine tutors and from 12 students who completed the program in 2010. The nine tutors all responded to a series of directed cues in a questionnaire administered by e-mail and the students contributed free-written 250-word reflective logs in the LMS addressing the question of the learning value of the program's development of a sense of community. The questions asked the tutors were:

1. What sort of support do students studying writing in an online environment need and find?

2. What, in your view, are some of the ways that we can foster a feeling of community among our online writing students?

3. In what ways do you like the feeling of being part of a community can help online students of writing?

Because our method analyses data about others as well as ourselves, we draw from Polkinghorne's (1995) theory of narrative configurations in enquiry, enabling us to identify elements and themes in both our own stories, and those of our tutors and final year students. Seeking key themes and common understandings is a feature of autoethnographic approaches (Chang, 2008), but is also resonant with the form of thematic analysis Ryan and Bernard (2003) call 'theoretical sensitivity' (p.88). This method draws on 'word-based' and 'scrutiny-based' techniques of readerly observation (Ryan & Bernard, 2003). Borrowing from Sandelowski (1995), we used a method of closely reading the material, identifying key micronarratives to understand everyday practices and underlining key phrases 'because they make some as yet inchoate sense' (p.373). To ensure this data is controlled for this paper, we focus on micronarratives related to collaboration, community and identity.

While we acknowledge the limitations in a methodology reliant on self-reportage and small sample size, we maintain, with Polkinghorne (1998), that narrative of self as an academic autoethnography is a strong qualitative methodology; it is most appropriate in our discipline, Writing.

3. Our backstory

This section develops the story of how we came to teach online, including what unique features we saw as presenting new and valuable learning possibilities.

Since 2002, this postgraduate course has been delivered online, providing a virtual learning environment and learning and teaching community through Blackboard. As sections 4 and 5 reveal, online learning has provided both staff and students with challenging yet productive experiences regarding developing their own writing understandings and capacities as well as interacting with staff, peers and the possibilities of web 2.0. We have developed, and continue to develop, strategic intent to adopt appropriate technologies and pedagogical approaches (Salmon et al., 2008). For the past five years (2007-2011) subject enrolments have reached between 700 and 1000 per annum, and 5 graduates of the program have so far completed PhDs by artefact and exegesis, with another 20 candidates enrolled.

As early adopters, we were not hamstrung by paradigmatic thinking and were encouraged to produce 'imaginative and creative images' such as those Salmon described (2004, p.34). Funded by a grant, we were initially (2002) engaged by what we could do with a games-based CD-Rom for multimedia interactivity and how we could combine this with online delivery spaces where students could practice interactions with the materials, with one another, and with relevant expert information/ opinions/ deliveries from selected sites. This pedagogical innovation involved the provision of an interactive multi-media game 'G21: Australia's Cultural Dreaming' (Arnold, Green & Vigo, 1997-2003), dedicated web pages for each unit with virtual lectures delivered in print enlivened with visual interviews, weekly questions for discussion with links to relevant expert contacts, discussion threads as virtual tutorials, an interactive chatroom and virtual spaces for students to workshop one another's writing.

The excitement of asynchronous deliveries meant that we exploited fully what was different to time and space regulated f2f delivery: an early recognition of the timeless and non-geographic factors of cyberspace (Arnold, 2004). We applied student-centred principles, anticipating those of Palloff and Pratt (2005) and Salmon (2004), and developed a curriculum that enabled teachers to act as co-constructers of student learning towards particular goals in particular subjects. As we redevelop, we respond to such observations as LaPointe & Reisetter's (2008):

> Avoiding the use of the traditional FTF communication template, and creating instead new structures that make optimal use of the autonomy-supporting strengths of online course delivery, appears to be a necessary paradigm shift (p.655).

In our ongoing updating of units, lecturers have applied a range of agreed innovative principles, such as

- maximising opportunities for learners to develop autonomy and agency;
- utilising texts which privilege indigenous and 'other' voices;
- ensuring weekly tasks have different cognitive demands;
- maximising spaces for reflection for, in and on action;
- incorporating critical friendship in each unit as they are redeveloped;
- involving representatives of industry in our curriculum development;
- understanding how e-moderation scaffolds learning from lectures, hyperlinked texts and student-generated texts, balancing the need for individuals to develop new and confident voices with the collective impulse to work in online communities of learners.

This is a necessary compression of our narrative about the background to a course that began in 2002. It indicates how a narrative requires a reader and a purpose for that reader (Barthes, 1977).

4. The story of course developers and lecturers

Thus, as our backstory testifies, our unique activities in the asynchronous MA have arisen from a long interaction with theory and practice regarding the opportunities offered by cyber-deliveries including the dimensions of cyberspace itself. In practice, we have investigated what the cyber experience of learning spaces offers the developer of curricula that f2f deliveries may not, particularly the ‘multi-layered communicative experiences’ beyond ‘mouse click and keyboard activities’ (Reimann et al., 2003). We have developed interviews with lecturers and experts within dedicated subject websites that provide virtual lectures and tutorial spaces. The 3,000-5,000-word lectures are hyperlinked to a range of texts beyond the virtual classroom from, for example, streaming videos of book shows to archives of radio interviews with writers. The subject websites have weekly questions arising from lectures, leading learners to a pathway in cyberspace of relevant expert comments and offerings. Students share their own discovered sites with the e-learning community, in itself an empowering use of cyberspace for student contributions to e-curriculum.

A as we update materials, considering and utilising ‘multiple possibilities’ as they arise in the new technologies remains an essential element. These vary from, for instance, recommending downloadable mind-mapping and note-making programs, to exploring oral feedback, to exploiting social media as an informational tool and a supplement to e-communities located in the LMS. Interactivity, ‘capable of establishing a two-way connection between distributed participants for the exchange of audio, video, text and graphical information’ (Kreijns et al., 2003, p.346) affords multiple possibilities that we, as a community of learners, explore assiduously with staff and students.

In preparing and delivering this material, we acted in ways that developed unique e-learning and e-teaching methodologies. For example, both during the course’s creation (2002) and its recreation (2009-2012), we formed a *carpe diem*-style team. This included online designers and evaluators as well as staff who developed curriculum with a view to producing online electronic lectures and interactive complementary or supplementary tutorials, followed by an assessed environment for discussion, collaboration, community building and identity negotiation. We paid particular reference to e-tivities facilitating online learning (Salmon, 2003) and cybercollaboration in ways that were different from f2f presentations (Palloff & Pratt, 2005). We saw that whilst an excessive amount of the www is print-based, we could bring virtual (and real) people into videos, and design screens with their own aesthetics rather than being simulacra for chalking-and-talking heads (Arnold, 2004).

The capacity to connect with ‘critical friends’ (peers, colleagues), virtual learning communities (tutorial groups; industry-related, writing and professional groups); lecturers, guest lecturers and tutors (e-moderators, supervisors, mentors, experts) is another unique feature of our pedagogical applications of the web. The WWW is used as a dynamic place for curriculum to develop and change frequently and for the most up-to-date applications and information to be available to academics and students as they turn ‘information’ into knowledge. We concentrate on CoPs that ‘inform’ evolving voices as writers, abilities to support others in their learning community and potential to contribute to other future imagined communities, such as sites where writers present and publish their work.

Through lecturers’ interest in the scholarly discourse of writing, representation generally and cybertextuality, we bring to our e-curriculum development a depth of theory that provides a nexus between information and understanding. So electronic asynchronous learning and teaching spaces with access to web 2.0 and its social media interests us practically and theoretically. The theory involves an understanding of the practical implications of such areas of critical and cultural theory as the rhizomatic text (Deleuze & Guattari, 1981). Such a linearity of thinking is a way of understanding the possibilities of cyberspace as lateral. Just as grass ‘creeps’, so the multiple links and connections enabled by the vast resources of cyberspace can be seen as a new way of conceptualising e-knowledge interactions.

Postmodernist theories about textuality, discourse and identity (Barthes, 1977; Derrida, 1978) advance thinking about and practice of any linear analytico-referential knowledge-model being overtaken by lateral postmodernist discourse. Such a conceptual framework involves Ulmer’s ‘mystory’ (1989) and the dispersal of certainties in considering the practice of writing a discursive piece on a given topic that adds to academic knowledge. Briefly, Ulmer proposes that there is in academic writing the self and the researched, the conscious intellectual semiotic and that arising from storytelling. These insights, applied to learners writing in e-communities, open for learners multiple textual possibilities and present options for multiple, flexible writerly identities.

5. The story of tutor and student experiences

The stories of the tutors who e-moderate the ALN and the students who experience the program lie at the heart of this section. More specifically, we draw on a study of nine tutor reflections on the themes of collaboration in community (Andrew, 2009), and 12 MA students' freeflow reflections on the usefulness of the learning environment of the MA, with its emphases on critical friendship and learning in CoPs, written after they completed their final unit. The nine tutors whose words inform our story are largely graduates of the program who have undertaken professional development in e-moderation and who have worked a minimum of four semesters on the program. From these reflective narratives we extract a range of micro-narratives, reconstructed here to create a narrative of experiences (Polkinghorne, 1995), using the authentic voices of the writers.

The first micronarrative addresses the issue of whether the program's use of critical friendships and spaces for building partnerships and community adds substantive pedagogical value; all agree (one reservedly) it does. Tutor 1 holds the most representative and clearest *pro*-voice:

> The sense of community is highly constructive. Students relax and feel easier, ask more questions, find their own experiences relevant and learn more effectively. Many are amazed at the sense of community that can emerge through the digital environment … many students express genuine amazement at how supported they feel, not only via staff, but by each other. For many the sense of community between the students is the most important and valuable aspect of the course – and a completely unexpected bonus.

This tutor's discourse speaks for her students' senses of ease and amazement at the effect of the community support scaffolded into the program's delivery. The amazement she describes originates partly in the realisation that peers are assets as well as tutors and partly in the fact that such support is possible in a virtual environment. The following voices also testify to the learning value of being invested in the community, itself comprising skilled individuals:

> It's the quality of the people and relationships where the real learning takes place (Student 12)

> I have no doubt I've been in the company of some future best-selling authors, screenwriters and renowned academics (Student 9)

> I gained from having been exposed to committed students/ peers who were open in their participation on the discussion board that genuinely enjoyed sharing their vast knowledge and experience (Student 11)

> Along the way, I found companions who shared my passion, my belief, that this way forward is our particular life journey we must brave. We have supported and held out hands to help one another over those seemingly impossible parts of this journey. (Student 4)

In the student voices there is also consensus that sharing experience, reassurance and feedback within critical friendship is a key way to build supportive networks. This impacts on individuals' learning about others' creative processes as well as their own both in the present community and, quite explicitly, into future imagined ones:

> My fellow students and critical friends provide reassurance as well as feedback that creativity can be frustrating, sometimes difficult and a never-ending evolution of ideas but it is something we all need to do. (Student 2)

> The discussion between team members has been vibrant. We have exchanged samples of our proposed artefacts to get a feel for each other's work. (Student 9)

> There is no full stop to this post, in keeping with a lively future anticipated for the critical friendship network formed by our tutorial group. (Student 3)

> Feeling part of the professional writing community can allow students entrée and mentoring in a very competitive and quite nepotistic industry. (Tutor 8)

The CoP in which the students share and reflect is microcosmic of the wider world of writers' communities beyond the program - imagined communities: the professional organisations such as the Writers' centres recommended by tutor 8. For such future and imagined communities, though, some students are unready:

> I am reluctant to step beyond familiar, imposed structures of the course into future in which I must find my own path. I am not ready (student 3)
> I've found this log a bit hard to write as I've psychologically shifted into break-up mode and haven't written anything on the computer for a few days (student 5)

These references to psychological reliance on community resources point to the need to use social networks to preserve the impetus on the learning and take us into the micronarrative on autonomy and agency. The ability to be an independent learner and a technological self-starter in the face of being physically isolated helps define the necessary learner orientation for those studying writing online:

> Working online has sometimes been difficult and yet it is at present, the only way I can attend a university. Aside from this course I do not regularly have the chance to discuss ideas, debate, share writing or cultural ideas. (Student 1)
> When people enrol in a distance-learning course, they assume a high-degree of individual responsibility for their learning, working with prepared materials to learn the terms, concepts, and skills presented there. (Tutor 2)
> Tutors need to demonstrate that working collaboratively on each other's texts has mutual benefits for all participants, as well as building writerly autonomy. (Tutor 3)

Working in communities ideally focuses writers on their weaknesses and tendencies in their writing so they can generate texts agentially. A related micronarrative focuses on individual writerly identities. There is a strong feeling that, while the community of learning was effective as a constructive and supportive mechanism, there was space in the pedagogic design for individual reflectiveness and learning about individuals' identities as writers:

> The course encourages them to think of themselves as writers from day 1 – and this is an important step in the development of their practice. (Tutor 1)

> All writing students are probably by definition centred on their writerly selves. (Tutor 5)

> And throughout my writing journey I have paused to look within. Who am I? What do I believe now compared to a year ago or ten years ago? Where do I want to go on both my inner and outer writing path? How will this change the other parts of my life? (Student 1)

> I have grown so much personally from the degree, which it has transferred across to my writing…. at the end of this journey I consider myself a writer and for that I am thankful to all as I couldn't have asked for a more concluded result. (Student 11)

The final micronarrative describes the most effective e-moderating and tutoring interventions for teaching and learning in a context of critical friendships and e-community:

The tutor should always provide positive criticism and say encouraging words whenever possible. This will make students feel competent and it will definitely do wonders to their motivation. (Tutor 9)

> The tutor can focus on working with students to master the content by using directed discussion to answer questions, stimulate critical reflection, and most importantly, give the student high-quality

> feedback and assessment of his or her performance on assignments and examinations. (Tutor 8)
>
> Feeling the need to be competent requires that the students challenge their beliefs, actions, and imagination, hence a tutor should never do is to criticise students harshly. (Tutor 7)

The tutor stands beyond the community of writers yet plays e-moderational roles of questioning, challenging, critiquing, validating and encouraging with authority.

6. Concluding our story

Our paper asked how our experiences of building and maintaining online communities of learners and engaging them in ‘critical friendships’ impacted on the student experience of studying Writing online and the tutor experience of e-moderating. The themes of community, collaboration and identity resound strongly as the uniting factors in our story of how we engage our online students of postgraduate writing. Engagement means students are *responsive* and *involved* and these also enable community building (Palloff & Platt, 2007). The Wengerian concepts of *mutual engagement, joint enterprise* and *shared repertoire* (1998) remain sound precepts, but writers also need space to grow, develop voices and imagine communities beyond the e-learning environment we created. The narratives of students and tutors suggest that positive experiences in learning situations like e-environments building critical friendship can achieve have impacts on motivation, learning and identities, potentially making future selves and membership in imagined communities beyond the e-environment seem more achievable. They also suggest that it is possible for teaching and learning in our e-environment to privilege the development of individuals’ writerly voices and identities, aided by tutor feedback, e-moderational interventions and, perhaps most revealingly, insights and critiques from peers.

The creation of an e-environment for writers emphasising critical friendship and learning in CoPs provides a focus for constructive, interactive, engaging text generation/ regeneration as well as a site for thinking about writing as a negotiated construction and the product of postmodern unfixed identities. This seems particularly apt as we continue to think about cyberidentities and cybertextualities. Social constructivist insights align with postmodern. Ulmer’s (1989) ‘mystorical’ approach, for instance, enables academic writing and language to be open, explorative and aware of its own evanescent nature. The texts that students create in our e-environment are hopefully ‘in-formed’ in that they construct knowledge out of textual, hypertextual and audiovisual lecturer input and cybertextual information beyond the LMS and apply it to their own generated texts; the process of coming to know ‘in-forms’ both their writing and their writerly identities. This process of becoming informed in turn enables writers to challenge and develop their individual voices and push the boundaries of their understandings of the forms and genres they write comfortably in. It’s an examination of self within an ideally trustworthy e-community still characterised by McMillan and Chavis’s ‘sense of community’ (1986).

Once again, the elements of community, collaboration and identity emerge as defining themes in the story of the origins and evolution of our program. It’s a story of learners’ challenging yet productive experiences regarding developing their own writing understandings and capacities as well as interacting with staff, peers and the possibilities of the www. It’s a story of lecturers’ *carpe diem*-style collaborations with web and learning designers, at the same time preserving the uniqueness of their own individual marks.

Broadly, our paper was an enquiry into what we learned that we could share with fellow providers of online learning. The story of the students and tutors acts as a reflective evaluation of the creation and recreation of an e-environment for teaching and learning postgraduate writing outlined in the story of course developers and lecturers. Amongst our learning, mirroring that of LaPointe and Reisseter (2008), is the need to foster autonomy and agency more strongly. We continue to struggle with how best to utilise what is perhaps the least considered element in e-learning communities: the logistically-unfriendly area of the aesthetics of the e-screen. Our aim throughout the processes of (re)designing and (re)delivering was and remains to provide a quality e-learning experience through curricula that utilise the possibilities provided by ‘the e’ itself, particularly the possibilities for collaboration, community and the negotiation of writers’ identities. Clearly, to echo Reimann et al. (2003), our students' burgeoning e-literacy and the multiplicity of possibilities arising in new technologies should be the basis for new learning opportunities for curriculum development. This is a story about creating a multi-faceted e-learning environment and the empowering use of cyberspace and being open to what Deleuze and Guattari (1987) might regard its rhizomatic potential. Like the story of lifelong learning in 'the e', this, too, is, and must be, an unfinished tale.

Changing student learning preferences: what does this mean for the future of universities?

Trish Andrews
Teaching and Educational Development Institute (TEDI)
The University of Queensland

Belinda Tynan
University of Southern Queensland

Learner preferences appear to be changing and there is some evidence that students are seeking a different kind of learning experience than currently commonly available. This paper provides a brief discussion of changing student learning preferences and suggests that these are being driven by the accessibility and characteristics of available and emerging technologies, rather than by technological determinism. The paper also suggests that, in many ways, the majority of higher education institutions are ill-prepared for these changes and that a gap is emerging between student expectations and student experience. It is proposed that students are looking for more connected and mobile learning opportunities and that 'loose networks' are playing an increasingly important role in supporting learning. The paper discusses the implications these changes have for institutions and suggests that while universities face challenges they also have choices.

Key words: learner preferences; mobile learning; social networking; loose networks.

Introduction

The ownership of mobile technologies is becoming increasingly widespread and many of these devices enable ease of access to a range of tools including social networking tools and rich media experiences (Traxler, 2011). The statistics indicate that this growth in ownership and use of these tools, while more widespread amongst young people (Jones, 2011), is by no means confined to this group, with many older people both going online and participating in social networking activities (Lenhart, Purcell, Smith & Zickhur, 2010). This growing use of technology by students of all ages, is having an impact on teaching and learning as students are increasingly seeking to use their own technologies (Andrews & Tynan, in press; van der Werf & Sabatier, 2009) to engage in a range of academic activities. As Williams, (2011), points out, students are looking for more engaged learning experiences using these tools and a move beyond the strong focus on delivery of information that still dominates much of higher education teaching.

Technological determinism versus 'networked individualism'.

Over the last decade the notion of the 'Net Generation' as a homogeneous, wired, group with high-level digital skills has gained currency and persisted (Tapscott, 2009; Oblinger & Oblinger, 2005; Prensky, 2001). This has influenced much thinking and debate around the provision of education for this generation, including the need to focus on greater engagement for these learners. This view takes a technological determinist approach, which suggests:

> The ubiquitous nature of certain technologies, specifically gaming and the Web, has affected the outlook of an entire age cohort in advanced economies (Jones, 2011, p. 42).

However, there is substantial evidence emerging that this group in fact demonstrates considerable variation in the ways in which they use technology and much recent research has sought to refute the notion of homogeneity and to highlight the diversity within this group (Jones et al., 2010; Kennedy et al., 2009; Fitzgerald & Steele, 2008).

Further, as Jones (2011; 2010) suggests, rather than a generation being defined by the time into which they were born, it is the technology itself that is affording change:

> The new technologies emerging with this generation have particular characteristics that afford certain types of social engagement. (Jones, 2011, p. 42).

This position is supported by emerging evidence that learners of all ages are embracing technology and are aware of the opportunities that mobile and web 2.0 technologies offer them to support both mobile and connected learning (Andrews & Tynan, in press; Williams, 2011).

Students' use of their technologies for teaching and learning

Recent research by the first author found that students are tending to use technology for teaching and learning activities in a number of interesting ways (Andrews & Tynan, in press), the first being individuality in this use. Students are demonstrating a high level of distinctiveness in their use of ICT to fit learning into their busy lives. As learning environments are become increasingly mediated by technology and students are heavily committed with families, work and other pressures they are utilising technology to engage in learning in very different ways.

The second way students are utilising technology has to do with mobility and connectedness. While concentrated learning is still important, they also appear to plan and manage their learning in smaller mobile bites. Few students are without devices that allow them to connect to the internet and access their learning, while on the move. As mentioned previously, the use of both mobile devices and social networking is increasing across all aspects of learners' lives regardless of age. Use of students' personal technology for learning purposes is evolving. Madge et al., 2009 found that on-campus students are using Facebook for mainly social purposes. Selwyn (2007), however found that while the primary use of Facebook for on-campus learners was social support, he also found that they used it for a range of transactional activities and low level teaching and learning activities:. These activities included:

- Recounting and reflecting on the university experience
- Exchange of practical information
- Exchange of academic information
- Displays of supplication and/or engagement
- Banter.

The third way students are using technology is in regard to resourcefulness and this is resulting in a shift away from using social networking tools as largely tools for social interactions, albeit, at times around issues related to learning (Selwyn 2007). Learners are seeking out their peers as a first point of call to resolve problems. As

Andrews & Tynan (in press) found, distance learners of all ages are appropriating Facebook and other social net working tools to support a range of teaching and learning activities including online discussion forums, creating repositories for learning artefacts and supporting special interest groups. Additionally Andrews & Tynan (in press) found that the use of 'loose networks' (Traxler, 2011) was used by students to support a variety of informal learning activities. Jones, (2011) also comments on the emergence of 'loose networks'. While little is understood yet as to how these networks operate, the availability of mobile and social networking tools appear to enable to students 'dip in and out of' activities and engage with a range of different peer learners to support particular learning needs (Andrews & Tynan, in press; Traxler 2011) as and when it suits. Meeting the diversity of student needs in this regard will become a challenging issue for curriculum designers and teachers. As Anderson (2008) has already pointed out, diversity in the need for connectedness will increase the difficulties faced by institutions in meeting the range of learner needs.

An emerging gap

Tools such as Facebook, Twitter, SMS and Skype are freely available to students and along with widespread ownership of mobile devices is providing an endless range of affordances for use for both personal and learning activities that students are increasingly appropriating. Hughes, (2009) suggested that the ways in which learners might want to learn and the ways in which universities are providing learning is creating a disjunct for learners. Despite the rapid acquisition of technology and the increasing focus on blended learning, most universities remain largely mired in a 20th century approach to pedagogy which focuses on transmission of knowledge. While technology is widely adopted and used across the sector, it still serves mainly as a means of delivering information rather than supporting and fostering engagement (McKeogh & Fox, 2009). The affordances of Web 2.0 tools are clear to many students (Andrews & Tynan, in press; Williams 2011) but mostly overlooked by the majority of lecturers (McKeogh & Fox, 2009; Lonn & Teasley, 2009). Although technologies such as learning management tools including Web 2.0 tools are widely available, most teachers simply adapt the basic aspects of these technologies to their existing teaching and learning practices, rather than change the way they are teaching to make more effective use of the technology to enhance learning (Gosper et al., 2009).

Further to this, Hughes (2009) also suggested that while the current generation of learners appeared to be tolerating this disjunct, the next generation might not be so accommodating. There is evidence emerging, however, that the current cohorts of students, regardless of any generational orientation in relation to using technology (Jones, 2011), want to learn differently and are already actively seeking changes to the ways their learning is provided to them (Andrews & Tynan, in press; Ram, 2010).

However, although recognising that change is occurring in the world at large, institutions have been generally slow to respond to changing learner preferences. Supporting Gosper et al's. (2009), observation in relation to the reluctance of many staff to change their practice to integrate new technologies Elhers & Schneckenberg (2010) point out that there is a general lack of interest and engagement by many staff in using technology effectively for teaching and learning activities. The situation is compounded by a general lack of attention to quality considerations for online learning and universities may not have strategic plans to address a changing environment. Consequently, these factors can cause paralysis in many institutions (Elhers & Schneckenberg, 2010) limiting their ability to respond to the changes occurring as a consequence of the ways technology is increasingly being uses in the broader society how this is impacting on universities.

The implications for learning in higher education

Some commentators (Bates, 2010; Ram, 2010; Williams 2011) suggest that given the availability of information enabled by ease of access to the internet and the ways in which mobile technologies and social networking tools support activities such as knowledge construction, that the future of universities as we know them will inevitably have to change:

> There is little doubt technology is not only changing the way we teach and learn, it is also challenging centuries-old academic structures and practices, the very notion of what it means to be literate and, potentially, the primacy of universities as the world's arbiters and repositories of knowledge (Williams,

2011, p12).

Bates, (2010) suggests that institutions have an emerging responsibility to ensure that all stakeholders involved in the student learning journey are cognisant of the way in which knowledge, its access and production is changing. Furthermore that the ways in which we teach may need to be altered and reconsidered alongside this. Further to this, Salmon, (2010) suggests that universities might a focus on 'capacity building, partnerships and collaborations' (p.40). This focus could enable the sector to more effectively support both leaners and staff needs.

From this perspective, taking a proactive position and providing a responsive culture and policy environment (Elhers & Schnekenberg, 2010) that has a focus on meeting students expressed learning preferences appropriately, could be seen as a viable way forward for institutions. This does not suggest that universities should respond uncritically to students changing expectations. Indeed, as Salmon (2010) suggests 'A more sophisticated and involved view of the 'net generation' and its need for learning needs to be taken (p.40).

However as Bates (2010) points out, the nature of most institutions means that these kinds of activities and associated changes will not necessarily occur in many institutions. To address this, amongst other strategies he suggests that support from government agencies will be necessary. This might include the provision of greater incentives for institutions to change, appropriate credentialing for university teachers and improved recognition of and incentives for innovations in university teaching,

Conclusion

This growing ownership and use of technology by learners of all ages, is having an impact on teaching and learning as students are increasingly seeking to use their own technologies. They are mobile, connecting in ways in which we do not fully understand and are resourceful in doing so. Knowledge construction is moving into new areas outside the control of academics. Most institution are struggling to address the changes currently occurring as a consequence of the widespread availability and use of technology. However, along with improved understandings of the learning needs of those entering universities (Andrews & Tynan, in press) more strategic approaches to innovation supported by appropriate Government incentives can be seen as possible strategies for minimising the gap between learner expectations and institutional responses.

Virtual environment as a collaborative platform to enhance pupils' information literacy skills

Sivagouri Arunasalam

The Internet has erased international boundaries allowing our young charges the potential to develop as global citizens. Research studies have given good insights on the role of information literacy on the effectiveness of learning. However, very little studies demonstrate an effective implementation of programmes in virtual learning environments. The paper highlights how Beacon Primary School, one of the futuristic schools in Singapore, has implemented its Tamil Language programmes in a virtual learning environment thus providing a collaborative platform for pupils to meet and discuss issues. P4 Tamil curriculum and lesson packages are designed to infuse Information Communications Technology (ICT) meaningfully and make virtual learning a reality. Information literacy had been weaved into the P4 Tamil language curriculum with online Web 2.0 software, wikispace, PBworkspace, as the platform for collaborative virtual learning environment. This paper presents how the virtual environment acts as a collaborative platform to enhance the pupil's information literacy skills.

Keywords: Virtual Environment, Information Literacy Skills

Introduction & Purpose

Pupils are surrounded by a wealth of knowledge. Today, at the click of a button, students have access to events occurring anywhere on the globe within seconds of it happening. Given this scenario, it is critical that our pupils are equipped with the skill to connect, construct and relate the information presented. The virtual environment provides the space for collaboration amongst pupils. The virtual environment eases and enriches the process out of which meaning is derived from the multitude of information presented. The virtual environment also presents a knowledge-based forum for pupils to build on each other's contribution.

Today's educational system has to respond to two seemingly contradictory demands. On one hand, it has to effectively transmit constantly evolving knowledge and know-how to a knowledge-driven civilization. On the other hand, it has to enable learners with the right skills to select pertinent information out of the explosion of available information. It also has to ensure that the personal and social development of the young learner is catered for. Therefore "education must ... simultaneously provide maps of a complex world in constant turmoil and the compass that will enable people to find their way in it" Delors (1996). This translates to a shift in focus for the amount and level of content taught in schools. It also calls for greater emphasis on equipping our pupils with relevant skills to pick out relevant information. This forms the basis of the nation-wide initiative of 'Teaching Less, Learning More'[1]. In today's context, the ability to access, evaluate, organize and use information in order to learn, problem-solve, make decisions in a formal and informal learning contexts are an integral part of their learning. A key characteristic of the lifelong learner is strongly connected with critical and reflective thinking.

Information communication technological tools are constructive tools that provide a collaborative platform for pupils to come on board and build on each other's knowledge. "Constructive tools are general-purpose tools that can be used for manipulating information; constructing one's own knowledge or visualizing one's understanding" Lim & Tay (2003). Jonassen, Carr & Lajoie (2000) purport the following constructivist approach - "ICT as mind tools for constructing evaluating, analysing, connecting, elaborating, synthesizing, imagining, designing, problem-solving, and decision-making." The term "constructive" stems from the fact that these tools enable students to produce a certain tangible product for a given instructional purpose. This paper takes a reflective, narrative approach in documenting our attempts to integrate the virtual environment as a collaborative platform in enhancing pupils' information literacy skills. This paper is my attempt to share possible strategies in integrating information literacy into our daily lessons. It is through such sharing and exchanges where ideas could build upon ideas to further push the boundaries of our pursuit for pedagogical break-through in this fast changing world. The paper examines how the integration of information literacy into Tamil lessons may improve the Tamil language competencies of the students.

My Reflections

One of the key themes in the Primary 4 curriculum revolves around the topic of 'My Country'. The broad objectives include exposing students to the various issues that surround the country. The lesson design is tailored to educate on the various national issues, including the importance of tourism and consequently make logical connections to the implications and impact it poses to Singapore's economic growth. The lesson was planned and carried out via the virtual learning platform as a collaborative platform for pupils to virtually meet discuss and develop their knowledge on the issue.

The discussion began from an article on Tourism from the Singapore local Tamil newspaper, Tamil Murasu. The teacher posted questions adopting the Blooms Taxonomy to scaffold pupils' skills up to the different stages. Relevant links for extended learning was also provided. These links however, was in the English language. Pupils were instructed to explore these links independently and gather pertinent information. They were subsequently asked to present them coherently in the Tamil language.

Pupils were taken through three main stages:

1) Connect – refers to the understanding of the article/ information presented.

2) Construct – refers to the pupils' ability to comprehend the information, build on possible relationships and extend their knowledge and understanding from the information presented collectively in the platform.

3) Relate – relates to the presentation of collective information, analysis, synthesis, evaluation and creation of new perspectives from the issues presented. The following section details the activities conducted as part of each of the stages.

[1] 'Teach Less; Learn More' (TLLM) is a call for schools and teachers to focus more on the active learning of students and the construction of their own knowledge.

1) **Connect:**
   - Pupils were asked to highlight the keywords and use the mind mapping technique to identify all the important points in the article.
   - Each pupil is to contribute one finding from the article via online postings.
   - Pupils also verified their friends' understanding of the article and their related thoughts.
   - If there was a misunderstanding of aspects in the article, the responsibility lay on fellow mates in the team to post a more accurate interpretation of the information.
   - The teacher acts as a facilitator to ensure that pupils connect with their ideas.

2) **Construct**
   - Pupils paraphrase, translate or give a short summary to express their comprehension of the article and the related issues.
   - In response to the questions raised, other members in the class contribute and build on one another's ideas via the platform.
   - The pupils' understanding of the content matter becomes apparent when they are able to identify relationships amongst ideas posted.
   - Pupils also tap on prior knowledge to build on these ideas.

3) **Relate**
   - Pupils are challenged with questions that require them to analyse available information and find logical patterns.
   - Pupils then evaluate the information and relate it to the current situation and seek new perspectives and understanding.

Pupils were observed to be very engaged and used the language appropriately. However, there were instances where pupils used English language to express their ideas, instead of Tamil. Although pupils were strongly encouraged to use Tamil language, weaker pupils who needed to resort to code-switching to express their thoughts, were not discouraged. The other pupils in the subsequent postings helped to translate these ideas. This created a win-win situation for pupils to tap on and maximise each other's strength and to learn collaboratively.

As part of the school ICT program, pupils were introduced to search engines and were guided in searching for the relevant information. Pupils were also taught principles of cyber-wellness and exercised civic respect in contributing ideas and in providing feedback and comments in the online platform. The contributions of students to the discussed topic and the postings of links leading to other related information was motivating. Even students who were less proficient in the language displayed interest in contributing to the discussion. Their posting displayed the collective understanding of the various points contributed in the platform. As all pupils had to work with their own personal learning, the learning was seamless.

The second extensive discussion took place after Japan's natural disaster. Pupils were exposed to this information during the morning assembly programme. As an extension an article from the newspaper was selected for online discussions. There was an intense discussion amongst pupils including the implications to the society and country. Pupils related the probable consequences. They were able to relate chain actions that would take place because of this disaster. Pupils used the Internet search engines to look up for latest update on the disaster such as on the British Broadcasting Corporation (BBC) news website. It was gratifying to note that the students took it upon themselves to update one another on the latest developments. In addition, they discussed and evaluated the situation and thought about the loss of those affected and the possible implications on their lives. It was heart-warming to note pupils expressed concern and empathy for those affected.

Discussion & Conclusion

Technology is used as a constructive tool to facilitate pupils' learning and making sense of their learning via a collaborative platform. Pupils' engagement was evident throughout the discussion. They were critical about their contributions and took great responsibility in actively using the net to search for information to enhance their learning. The project had benefited even pupils, less proficient in the Tamil language, who was observed to be actively contributing ideas. There was sincere commitment on the part of the students. They also showed initiative in providing additional links and support for others to make sense of the issue. This helped to bring out the best in each pupil. Pupils in addition, expressed positive feedback. Every pupil contributed and has equal share in collaboratively constructing the knowledge, thus the ownership was very strong amongst them. This was a demonstration that young age is not a barrier in understanding world issues if it is tailored to meet the needs of the young learners. What really matters is whether pupils are equipped with skill to understand the implication and impact of the issue discussed.

In terms of skills, all pupils were able to sieve out and decipher the main points from the information presented and build on this information. Through this communication, it was observed that pupils had tapped on prior knowledge and experience in developing their alternative perspectives. Pupils learned to use the information and ideas presented in a graphical organising format to organise ideas. Pupils exhibited strong bonding and collaboration during the various collaboration sessions. The usage of technology was pervasive and as Breivik (2000) puts it "Information literacy (is not)... teaching a set of skills but rather a process that should transform both learning and the culture of communities for the better."

Unpacking TPACK and students' approaches to learning: Applying *knowledge in pieces* to Higher Education teaching and learning

David Ashe & Shaista Bibi
CoCo, Faculty of Education and Social Work,
The University of Sydney, NSW.

This conceptual paper considers how the TPACK (technological, pedagogical and content knowledge) framework (Mishra & Koehler, 2006) can be used to gain an understanding of technology use in teaching and learning. For technology to enhance traditional teaching and learning, TPACK itself may require a tighter definition. We consider the effects of incorporating technology on both teachers' knowledge and students' approaches to learning. The intention is to look deeper into the TPACK construct and to view it from an alternative theoretical perspective. diSessa (1988) proposed a 'knowledge in pieces' theoretical approach that enables a finer-grained scrutiny of knowledge. This theoretical perspective considers knowledge to consist of small elements or 'resources'. We propose that 'knowledge in pieces' may help provide a better, more nuanced understanding of both TPACK and how technology-driven contextual change can affect learning. We conclude by outlining some implications of this theoretical perspective for future empirical research.

Keywords: Teaching; learning; TPACK; knowledge in pieces; teachers' knowledge; technology.

Introduction

Teaching in higher education requires the use of many different types of knowledge. This knowledge is diverse and includes both content and pedagogical knowledge. In recent times a new type of knowledge has been attracting attention, that of technological knowledge. Mishra and Koehler (2006) provide a framework for considering the integration of these types of knowledge that they refer to as TPACK (technological pedagogical and content knowledge). They describe TPACK as "an emergent form of knowledge that goes beyond all three components" (Mishra & Koehler, 2006, p. 1028). The implication is that this new form of knowledge is greater than its constituent parts. Angeli and Valanides (2009) consider TPACK to be an emerging type of knowledge that still needs a tighter definition. Furthermore, they question whether TPACK is a distinct/unique body of teachers' knowledge, constructed from other forms of knowledge, or whether TPACK is the integration of existing forms of knowledge.

The use of technology in higher education is largely accepted to be an integral and expected part of the student experience. This paper looks at the implications of applying a TPACK framework to teaching and how technology can affect students' approach to learning. We look at how teachers in higher education can incorporate technology effectively into their teaching and how technology can be utilised to shift the context of learning to affect the learning process. To investigate the implications of technology in teaching and learning, a 'knowledge in pieces' perspective will be suggested as a useful theoretical lens.

Knowledge in pieces

The way the human mind works, and how knowledge is created, stored and used, remains elusive. One traditional view is that of 'schema'; a theory that suggests that as knowledge is acquired it is abstracted and stored ready for use at another time (Sawyer, 2006). When presented with a new problem or situation, the mind locates an appropriate schema to make sense of the situation. This theory suggests that individuals have stable and coherent states of knowledge; once a schema has been created it is available at all times. While helping to explain much about how thinking and knowing takes place, this view does not explain how some knowledge appears to be available in one context, but not available in another.

diSessa (1988) introduced the theory that knowledge comprises many small, fine-grained elements that activate, or do not activate, depending on context. These elements, which diSessa describes as "phenomenological primitives" (p-prims), appear self-evident to an individual and require no explanation. Considering knowledge at a much finer grain-size provides the possibility of explaining how an individual can hold opposing knowledge positions without noticing any problems caused by the conflict. For example, one piece of knowledge that an individual may hold is that motion requires the continued application of a force (I push a cup across a table and it moves, when I stop pushing it stops); the same individual can also hold another piece of knowledge which states that motion does not require the continued application of a force (I toss a coin in the air and it continues to move after I have let it go) (diSessa, 1993). These two elements of knowledge are in conflict. They are, however, often held simultaneously without the conflict being noticed. The context has changed (pushing a cup versus tossing a coin) and hence different knowledge elements are activated. The 'knowledge in pieces' theory has been used to provide insights into various issues in higher education, such as transfer (Wagner, 2006), pedagogy (Goodyear, Markauskaite, & Kali, 2009) and epistemology (Hammer & Elby, 2002). We suggest that this theory may also provide a better, more nuanced understanding of TPACK guiding the understanding of technology use in higher education.

Higher Education: Teaching with technology

Teachers' knowledge of technology, and how technology is integrated into the curriculum, has become a major focus of research. Graham, Burgoyne, Cantrell, Smith, Clair, and Harris (2009) state that knowledge related to the effective use of educational technologies has become widely recognized as an important aspect of an educator's knowledge-base for the 21st Century. Technology, in this context, incorporates more than the use of ICT tools; it is the creation of complex relationships between artefacts, users, tools, and practices (Koehler & Mishra, 2005). Higher education institutions are focusing on technology-facilitated learning environments to improve the quality of the teaching process. Ertmer (2005) reports that technology is now considered to be an integral part of providing a high-quality education. Further studies indicate that the use of technology in education demands that teachers develop their knowledge of technology and hence become more able to integrate a range of technology tools effectively into their teaching (see Goodyear, Jones, Asensio, Hodgson, & Steeples, 2005; Yunus, Kasa, Asmuni, Samah, Napis, Yusoff, Khanafie, & Wahab, 2006; Zenios, 2006; Strampel & Oliver, 2007).

Mishra and Koehler (2006) stressed that, as well as being technology users, teachers should gain a proper understanding of the technology. This implies an understanding of how technology can be used to teach particular content and how content could be altered to make teaching with technology more meaningful for learners. Mishra and Koehler further posit that more effective and constructive teaching may rely on generating an understanding of the factors that make particular concepts difficult or easy to learn. This understanding, based on the integration of technological, pedagogical and content knowledge, could lead to innovative ways of incorporating technology into existing teaching practices.

Despite attempts to understand how TPACK is formed, there still appears to be a disagreement about the definition and nature of the combined knowledge (see Koehler & Mishra, 2009; Angeli & Valanides, 2009; Cox & Graham, 2009). Harris, Mishra, and Koehler (2009) suggest that TPACK is formed through many interactions between the component knowledge types. By fluently integrating different knowledge elements and by gaining an understanding of the interrelationships between the knowledge types, teachers may be able to switch between, and integrate, the three component knowledge areas of TPACK according to the context.

Considering the three component knowledge areas that make up TPACK (technology, pedagogy and content) as separate and isolated areas of knowledge, it is hard to understand how the combination of these areas can produce anything more than the simple integration of existing knowledge. However, considering each of these knowledge areas as being encoded in the form of smaller knowledge elements that may or may not be activated depending on context, provides the possibility of understanding how the combination can become greater than the parts. When some knowledge elements in one of the components of TPACK become activated, they may influence the activation of other knowledge elements from another component of TPACK.

Teaching with technology may change the traditional role of the teacher. Gonzalez (2010) outlines four roles that a teacher needs to appropriate when teaching with technology. These roles are: provider of online information, creator of communication spaces, facilitator of discussions, and designer of "knowledge building" environments. These roles may require specific knowledge, much of which is based on traditional pedagogical and content knowledge that needs to be integrated with technological knowledge. Seeking out the technological, pedagogical and content ‘p-prims’, and looking for ways that these knowledge elements interact, may provide a starting point that leads to a better understanding of teachers’ knowledge.

Higher Education: Learning with technology

Technology is often considered to be an additional tool, available to students to help with their learning. Selwyn (2007) provides an insight into the usefulness of technology from the students’ perspective. Rather than embracing technology as an effective learning tool, students take a more pragmatic approach to their learning, concentrating on those aspects that are most likely to help them reach their goal - a good grade (Selwyn, 2007). Unless technology performs a useful role in this respect, it may remain an adjunct. One way technology can help towards the students’ goal is by changing the context of learning.

It is thought that learning may be affected by the context in which the learning is taking place; individuals approach similar problems in different ways when in different settings. Lave (1988) shows evidence that when ‘real life’ problems are presented in school, the ‘situation’ part of the problem is generally ignored, or treated as some kind of *red herring*, designed to disguise the real problem. However, when a similar problem is encountered in real life, the situational context is not only recognised, it is used as an integral part of finding a solution (Lave, 1988). Carraher, Carraher, and Schliemann (1985) found a similar example of this mismatch of knowledge. They reported that knowledge became unavailable in certain situations; street sellers could make complex mathematical calculations when trading but were unable to perform similar calculations in a school setting. Interpreting this with a ‘knowledge in pieces’ theoretical lens, suggests that different knowledge elements are activated in the different contexts.

Technology may provide the possibility of changing a learning context, which may in turn help students activate different knowledge elements. Rather than limiting technology use in higher education to that of enhancing an existing pedagogical style, technology could also be used to change the context of learning. To understand the effects of changing the learning context, it may be helpful to investigate the process of learning and how that process can be varied when technology is introduced. Viewing the process of learning using a ‘knowledge in pieces’ theoretical approach may enable the identification of specific fine-grained knowledge elements (elements that are self-evident to the individual) that become activated. Discovering these knowledge elements and understanding the factors that enable them to become activated, and in which context, may provide a key to a better understanding of how context, and therefore technology, can change learning.

Implications for future empirical research

Gaining a better understanding of how technology affects teachers and teaching may provide an insight into effective use of technology in higher education. The use of technology as an integral part of the process of learning may also affect learners by varying the context of learning. A ‘knowledge in pieces’ theory provides a lens through which this can be viewed.

Further research will be necessary to investigate these two areas. Following on from work by diSessa (1993), Hammer and Elby (2002), Wagner (2006), and others, we suggest the following ways forward:

1. Explaining the nature of TPACK.

To gain a better understanding of how teachers utilise different knowledge types and how different knowledge elements are activated, it may be necessary to consider the 'thinking' process when teaching. Investigating a thinking process is challenging; knowledge elements, while self-evident to an individual, remain elusive to others. These elements may be detectable from observing teachers and also by undertaking content analysis of teachers' activities (such as planning and teaching sessions), employing techniques such as 'thinking aloud'. Observing differences in pedagogical and content 'p-prims', when technological 'p-prims' are activated, may lead to a better understanding of the nature of teachers' knowledge.

2. Understanding how technology can change the context of learning and how that change can affect student thinking.

To gain a better understanding of how students' thinking changes as context changes, it may be necessary to investigate the 'thinking' process during learning and how that process changes when a student is learning in different contexts. As above, investigating a thinking process is challenging and the challenge is increased by the necessity to study the process in different contexts. Observing students working in small groups may provide an insight into their thinking process as they articulate their thoughts to other members of the group. By analysing students' speech, while they are working on similar problems in different contexts, it may be possible to detect different knowledge elements being activated in the different contexts. Gaining a better understanding of how students learn, when technology has affected the context of learning, could be used to develop better technology-driven learning environments.

The blending of blended learning: An experiential approach to academic staff development

Debra Bath & John Bourke
Griffith Institute for Higher Education, Griffith University, Brisbane, Australia

Along with the increasing emphasis placed on blended learning approaches in higher education, has come a need to engage and support staff in developing knowledge and skills for designing and managing blended learning curricula. This paper describes one strategy for such support: an elective course within an existing Graduate Certificate in Higher Education program. Staff have the opportunity to complete this course as part of a formal program of study or as a one-off professional development opportunity. The course specifically aims to support staff in developing an understanding of the philosophical and pedagogical underpinnings of blended learning design, as well as in gaining skills in designing curricula from a blended learning perspective using information and communication technologies (ICTs) for teaching, learning and assessment purposes. Itself designed in blended learning mode, this course attempts to embody good practice in blended learning, and here we present an initial evaluation of the course from this perspective.

Keywords: blended learning, academic staff development, higher education, evaluation

Introduction

Blended learning is fast becoming embedded as the primary method of course delivery in most universities, both in Australia and internationally. Whilst there are likely to be varying drivers for this development across institutions, many would espouse the aim of engaging students and enriching the quality of student learning.

Despite the fact that the term ‘blended learning’ is now commonplace in higher education, there are differences in the interpretation and enactment of the concept. According to Wild (2007, p.1) at its most basic, blended learning is “…a blend or mix of the approaches that can be used to design a learning experience”. So, even though essentially “…Learning is always blended” (p.1) we typically take this concept to mean the use of technologies in learning through the integration of online and face-to-face modes. Along with the adoption of blended learning approaches has been the need for teachers to make more explicit their intentions for learning and teaching, and curriculum design is now a more considered process and outcome than perhaps ever before. When designing a course, teachers now have to contemplate the notions of place, proximity and technology, and make decisions about what is best for learning within existing possibilities and constraints. For example, what is the value of bringing students together in a single place and time? How is it different when students are learning face-to-face vs. online/distance, or in in real time vs. asynchronously? What resources do I, and my students, have access to?

Therefore, the move towards blended learning approaches has placed a great challenge on many teachers in higher education who are faced with a need, indeed an imperative for some, to acquire knowledge and skills in designing and managing blended learning curricula. This need is supported in varying ways within institutions, including formal academic staff development initiatives, one of which will be addressed in the present paper.

Context and overview

From 2008, blended learning has been an institutional strategic priority for our University, having set the goal to "…systematically embed blended learning approaches in the teaching and learning activities of all programs" and "…nurture and extend staff capabilities in the applications of blended learning" (Griffith University, 2007). As part of the institutional strategy for blended learning, an elective course was developed as part of the existing Graduate Certificate in Higher Education program. This program has been running for many years, and is completed by academic and allied staff from the University, as well as staff from other post-secondary education institutions. The new elective course is open to those completing the Graduate Certificate program, as well as any staff who wished to complete the course as an independent study option.

The blended learning elective course aims to support staff in developing an understanding of the philosophical and pedagogical underpinnings of blended learning design, as well as in gaining skills in designing curricula from a blended learning perspective, and in using information and communication technologies (ICTs) to facilitate communication, collaboration (interaction) among students, content delivery and assessment. Developing practical knowledge and skills in blended learning design and delivery is obviously an important aspect of this course. However, being able to identify and apply relevant theoretical concepts, and provide a rationale for what one does, is also emphasised and supported as an important aspect of professional practice.

This course was designed specifically to allow participants to experience blended learning first-hand, and thus was not just about blended learning, but was conducted in blended learning mode. This meant that we not only facilitated participants learning about blended learning, but we modeled a blended learning approach. Indeed, we needed to model best practice and provide an evidence-based approach to our own work. To this end, we worked from three key theoretical frameworks; each is briefly discussed below.

Technological pedagogical content knowledge (TPCK)
TPCK (Mishra & Koehler, 2006) is a conceptual framework for the use of technology in education, which builds on Shulman's (1986) notion of a teacher's 'pedagogical content knowledge' which reflects knowing what teaching approaches best suit the content, the representation and formulation of concepts, pedagogical techniques, knowledge of what makes concepts difficult or easy to learn, knowledge of students' prior knowledge, and theories of epistemology.

Mishra and Koehler (p. 1017) argue that 'thoughtful pedagogical uses of technology require the development of a complex, situated form of knowledge' that goes beyond all three components (content, pedagogy, and technology) and differs from the knowledge held by a disciplinary (content) or technology expert, and also from the general pedagogical knowledge shared by teachers across disciplines. TPCK is central to good teaching with technology, and it combines content knowledge, pedagogical knowledge and technological knowledge to form knowledge of how to use technology to best facilitate learning in a particular discipline, for particular content, contexts and cohorts. TPCK guided the design of both content and activity in the course, and placed an emphasis on facilitating participants' learning about technology within their personal teaching contexts.

Community of Inquiry
The Community of Inquiry (COI) framework for blended learning, developed by Garrison and Vaughan (2007), is founded on the belief that a framework helps to avoid separation of theory and practice and "…provides a means to shape practice…to reflect upon and make sense of outcomes…" (p. 13). They argue that the ideal 'educational transaction' involves a process of collaboration and construction with inquiry at its core, where such social interaction helps students to share knowledge, develop and evaluate meaning, and hence enrich their understanding.

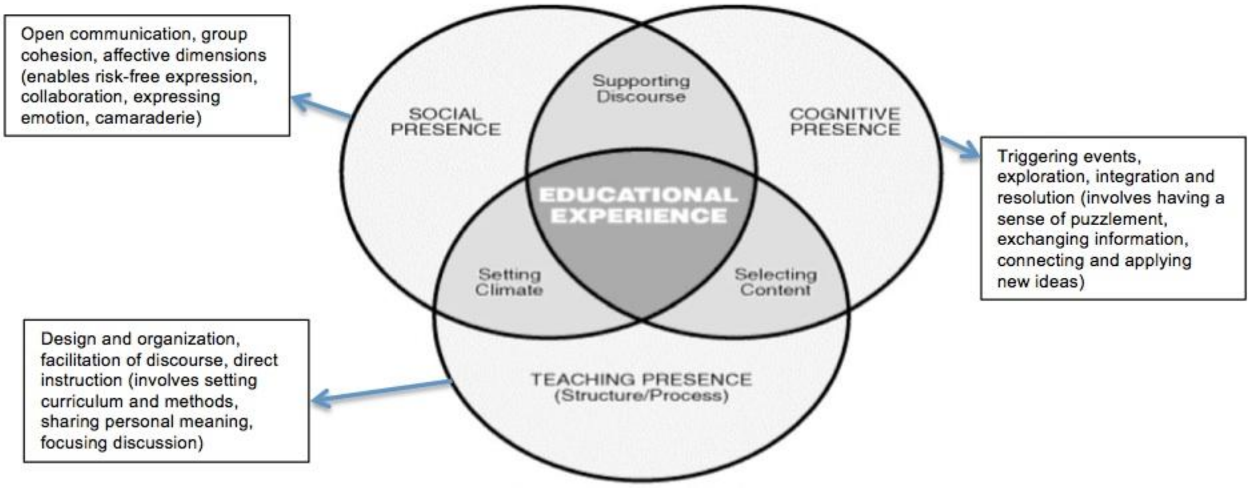

Figure 1. The Community of Inquiry Framework (Garrison & Vaughan, 2007, p. 17-18)

Their framework involves three key components; (1) *Social Presence* - the ability of participants to project themselves socially and emotionally in the community, through trusting and purposeful communication and interpersonal relationships, (2) *Cognitive Presence* - the extent to which learners are able to construct and confirm meaning through sustained reflection and discourse, and (3) *Teaching Presence* - the design, facilitation and direction of cognitive and social processes to create personally meaningful and educationally worthwhile learning. Research has shown (Garrison & Vaughan, 2007) that teaching presence is a significant determinate of student satisfaction, perceived learning, and sense of community. The COI framework guided the holistic design of the course, and then the ongoing delivery and management of the course experience.

Experiential learning

In addition to the TPCK and COI frameworks, the design of the course was underpinned by an experiential learning approach. Experiential learning involves learning from experience, from a direct encounter with the phenomena being studied. Kolb and Fry (1976) proposed that learning is continuous and cyclical, where it is formed and re-formed through the individual's experience; what is essential in the process is reflection and reconceptualisation in order for new experiences to be integrated with prior knowledge and for knowledge to be built upon. In their model, learning begins with *concrete experience* (doing, having an experience), which leads to *reflective observation* (reviewing, reflecting on the experience), and *abstract conceptualization* (drawing conclusions, learning from the experience) in order to move on to *active experimentation* (planning, then trying out what one has learned). This model of learning was perhaps the most fundamental to the course, as it underpinned both TPCK and COI frameworks and provided both teachers and participants in the course a simple yet effective purpose and guide for learning.

Course structure and activities

The course is structured around three face-to-face workshops (o-week, mid-semester break, study week), which were designed to: support the creation and maintenance of a sense of connection and community amongst the group; facilitate learning of key literature and some technical skills; and debrief online activities, share and discuss experiences. During the semester, between workshops, the course is segmented into four learning modules, which include set readings and activities made available online, and supported by three online tutorial sessions using Wimba Virtual Classroom. These include: (1) Designing for student activity and collaboration (small group wiki task, discussion forum x 2); (2) Assessment and blended learning (develop marking rubric for wiki task, self and peer assessment of wiki task); (3) Building a learning community (virtual tour of online course); and (4) Evaluating blended learning (develop evaluation tool).

The formal assessment tasks are mostly embedded within the learning and teaching activities throughout the semester, or draw heavily on these activities. For example, to support students from an experiential learning approach, they are required to complete a reflective journal (using an individual blog tool). The small group wiki task is also a set assessment task, and participants are required to utilise their discussion forum posts in another assessment task. Drawing together their learning throughout the course, participants are finally required to design a sequence of activities that are focused on a particular learning objective (chosen by the individual, and can be hypothetical or a real learning objective from his/her own teaching experience). To facilitate the design process, we use the LAMS (Learning Activity Management System) tool, which provides a user-friendly authoring (i.e., designing) environment for creating sequences of learning activities that can be shared with others. Participants submit their LAMS design along with a report detailing the relevant pedagogical approaches, their design rationale, and an implementation and evaluation plan.

Evaluation

In addition to the University mandated student evaluation of course and teaching process, we implemented an evaluation based on the TPCK and COI frameworks that underpinned the design of this course. These evaluation components were also embedded as part of the course itself, and are described in turn.

In order to support and evaluate participants' development of knowledge and skills in blended learning (from a technological pedagogical content knowledge) we designed a self-evaluation instrument that participants completed before and after the course. Using an online survey (www.SurveyMonkey.com) participants rated their own knowledge and skills related to blended learning, both in terms of level (from 1 = not at all, to 6 = extensive) and confidence (from 1 = not at all, to 6 = complete). They were encouraged to reflect on this experience and what it meant in terms of their learning, and to note this in their reflective journals. The overall results are presented below. Because of the number of items included in the instrument, related items were grouped together for statistical analysis; Knowledge (e.g., "…the learning and teaching theories that underpin blended learning design"), Ability with blended learning tools (e.g., "…using a virtual classroom (e.g., Wimba) in your course/practice"), Ability to manage blended learning (e.g., "…effectively managing a technology-rich/blended learning course"). At the beginning, participants also rated themselves in terms of the frequency and level of technology use in teaching; the majority (87%; 13 of 15) rated themselves as low (very little use) or medium (used a few different tools/technologies). Therefore, it is not surprising that at the beginning most rated their knowledge and skills, and associated confidence, quite low (see Table 1 below). There was a significant change in participants' ratings across all groups of items, indicating that as a result of the course the participants experienced an increase in their knowledge and skills, and also felt more confident.

The COI model was introduced at the beginning of the course, and was specifically incorporated into the set readings and discussion forum activities in the first module. Towards the end of the course, as part of exploring online survey tools, participants completed the COI survey (Arbaugh et al, 2008). As can be seen by the results in Table 2 below, participants rated teaching presence indicators most positively. Cognitive presence indicators were also rated quite highly with integration being the most positive (i.e., combining new information helped me answer questions, reflection helped me understand fundamental concepts). Aspects of social presence were rated least positively, which is commensurate with other course feedback indicating that participants wanted more face-to-face contact, particularly early in the course.

Table 1: Participant evaluation of their knowledge and skills in blended learning

Level of knowledge & skills	*Mean*	*SD*	*Confidence in knowledge & skills*	*Mean*	*SD*
Knowledge level: pre-course	2.28	0.99	Knowledge confidence: pre-course	2.41	0.91
Knowledge level: post-course	4.69*	0.75	Knowledge confidence: post-course	4.69*	0.76
Ability with BL tools: pre-course	2.2	0.93	Confidence with BL tools: pre-course	2.68	0.85
Ability with BL tools: post-course	4.33*	0.89	Confidence with BL tools: post-course	4.38*	1.02
Ability to manage BL: pre-course	2.23	0.93	Confidence to manage BL: pre-course	2.61	0.85
Ability to manage BL: post-course	4.42*	0.83	Confidence to manage BL: post-course	4.49*	0.95

* Significant difference between pre- and post-course ratings, with t values ranging between 5.58 and 32.80, $p < .001$.

Table 2: Participant evaluation of COI components of the elective course

Teaching Presence	*Mean (SD)*	*Social Presence*	*Mean (SD)*	*Cognitive Presence*	*Mean (SD)*
Design & Organisation	4.16 (0.42)	Affective	3.58 (0.87)	Trigger Events	3.82 (0.70)
Facilitation	4.23 (0.32)	Group Cohesion	3.73 (0.51)	Exploration	3.67 (0.60)
Direct Instruction	4.15 (0.40)	Open Communication	3.64 (0.66)	Integration	4.03 (0.59)
				Resolution	3.94 (.042)

Note. Responses were made on a scale of 1 (strongly disagree) to 5 (strongly agree)

Summary and conclusions

As suggested by Garrison and Vaughan (2007, p.13), working from an explicit framework in designing this course on blended learning provided us with 'a means to shape practice…to reflect upon and make sense of outcomes…" by carrying this framework through into our evaluation. Although brief, the data presented directly reflects the design of the course and together with the work produced by participants, allows us to evaluate and reflect on the success of the course in terms of it's underlying philosophy and aims. Whilst participant feedback was positive overall, and gains in knowledge and skills significant, participants felt the need for greater face-to- face contact and earlier development of social connections. This is not surprising, as lack of social interaction or connection is often a reported concern of online students (Smart & Cappel, 2006). However, using the COI model and survey allows us to more richly explore this issue, and continue to modify and adapt our blended learning practice.

Interactive Webinars – the future of teaching and learning online

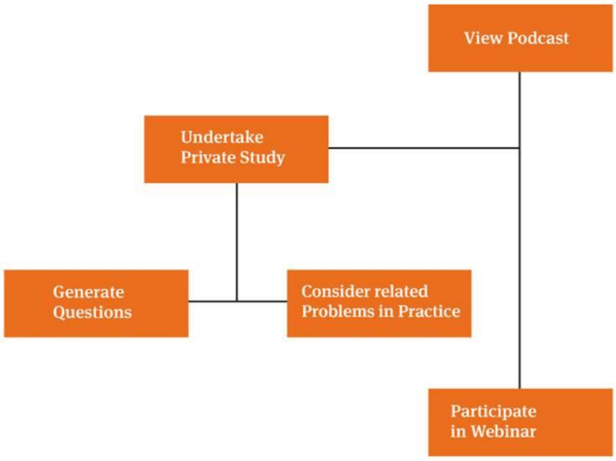
Ms Susan Batur
e-Learning Project Officer, Australian and New Zealand
College of Anaesthetists

Ms Mary Lawson
Director of Education,
Australasian College for Emergency Medicine

Mr Oliver Jones
Acting General Manager,
Australian and New Zealand College of Anaesthetists

In recent years, a number of factors have contributed to the growth in both quantity and type of online educational resources made available to online learners. Two of these have been the speed of internet connections and advancing web technology. An example of this is the introduction of web-conferencing software, also known as webinars.

In 2009, the Education Development Unit (EDU) of the Australian and New Zealand College of Anaesthetists (ANZCA) introduced webinars as a collaborative teaching and learning tool for trainees preparing to sit the ANZCA Final Exam. This technology, coupled with the newly introduced video podcasts, offers learners a model of education delivered entirely over the internet with both synchronous and asynchronous elements (as described in figure 1.0 below). This model was developed based on adult learning principles, and building on experiential learning theory.



Web-conferencing technology has significant benefits to ANZCA and ANZCA trainees;

- **Collaborative learning:** Trainees are able to access expert information and support and not only access the information, but collaborate and interact in an online environment.
- **Far reaching contact and equitable access: W**eb conferencing technology allows interaction between geographically separated participants. Trainees from remote areas in Australia, as well as those located in New Zealand, Hong Kong, Malaysia and Singapore regularly participate.
- **Participation can occur anywhere:** Learners are no longer required to physically congregate in one area. All that is required for participation is access to the internet and a computer with speakers. This is particularly important for health care professionals with on-call and weekend commitments.
- **Visual: V**ideo feature gives the learner and trainer the social benefits of face-to-face interaction.
- **Instant messaging:** The 'chat' function allows learners to make comments whilst the trainer is talking without causing disruption.
- **Quzizzes:** The 'polling' function allows for on the spot quizzes to test knowledge acquisition and to provide immediate feedback to trainees on their understanding of the concepts presented.
- **Economical** – web conferencing technology is significantly more cost effective than installed video conferencing technology.

Roles

During the webinar, a variety of instructional roles have been developed to provide effective teaching and learning experiences to be provided. The role of moderator (or host) is undertaken by ANZCA staff from the EDU whose main role it is to offer any support that might be required. This has also required significant coaching on online delivery for inexperienced presenters.

The role of trainer (or presenter) is taken by an ANZCA Fellow who is online to make an expert presentation, pose and answer questions from the trainees who assume the role of attendees. To date, it has also been necessary to offer technical / administrative support for participants to assist with other aspects of attendance such as inability to logon, and requests for password reminders.

Trainees are able to ask the online trainer questions by either typing using the chat box feature or by using their microphone and asking their question using their web camera or in-built computer microphone. The process is exactly the same as it was in the traditional face-to-face environment that it replaces– the only difference here is that it is carried out completely online.

Format

During the interactive webinar, the trainer begins by giving an overview of the podcast that has usually been made available 2 – 3 weeks before the webinar takes place. They then invite the attending trainees to ask any questions they had in relation to the podcast topic. There are many features in-built to the online meeting space to encourage interaction amongst the trainees including the recently introduced ‘polling’ segment. This interactive component is similar to an online test where the presenter asks trainees pre-prepared short answer and multiple choice type questions. The trainees answer the questions by voting on the correct answer. The results submitted by the trainees are then shared anonymously and the presenter discusses the results.

The typical webinar format is as follows:

Typically, each webinar commences with ANZCA’s e-Learning Project Officer orientating the webinar participants to the online training environment. Time is also taken to introduce the webinar presenter and to provide instructions on how the participants interact with the presenter and each other.

The webinar presenter provides a brief overview of the content presented in the podcast. Trainees are expected to have reviewed this information in light of their own clinical experience thus encouraging application of the knowledge to their practice.

Trainees are invited to ask the presenter any questions they have in relation to the content delivered in the video podcast about the related topic. Participating trainees can ask their question either by typing in the chat box or communicating using microphone and webcam..

Short case-based discussions prepared by the presenter are shared with trainees in order to increase interaction. Short on-the-spot quizzes or multiple choice questions are also shared and trainees are able to answer by typing responses or talking online using a microphone and/or webcam.

The webinar ends with an end of session online evaluation form which all participants are requested to complete prior to exiting the webinar room.

Figure 2: The ANZCA Webinar format

Communication is challenging with a geographically dispersed working cohort and trainees are notified of webinar events through a variety of communications channels including; personal email invitations to Trainees; adverts in the ANZCA Trainee Newsletter, ANZCA website and ANZCA e-Newsletter. Supervisors of Training, Regional Education Officers and ANZCA Regional Staff are also requested to notify the trainees that they supervise or liaise with. Currently, ANZCA Interactive webinars take place on a monthly basis and the feedback from trainees is very positive. Formal evaluation data will be provided. Indicative quotes are provided below:

Due to the success of the current program, ANZCA will continue to invest in this technology to facilitate training for a broader audience, including International Medical Graduate Specialists (IMGS) and Fellows of the College interested in pursuing CPD opportunities and to formally evaluate the applicability of this innovative model in these alternative cohorts.

Plug and play learning application integration using IMS Learning Tools Interoperability

Simon Booth
University of Stirling

Susi Peacock
Queen Margaret University

Stephen P. Vickers
The University of Edinburgh

A key barrier to providing learners with engaging learning experiences is the deployment of new, innovative technology. This requires collaborative effort between teachers, system administrators and application developers. The shared goal is to make it as easy as possible for learning applications to be used by learners; the shared challenge is achieving this in a cost effective manner. The IMS Learning Tools Interoperability (LTI) specification provides new opportunities for addressing this issue and provides significant benefits to all three parties. Using LTI can provide developers and system administrators with a standard mechanism for integrating learning applications with existing systems (such as a virtual learning environment) and allow teachers greater freedom to select applications which best meet their pedagogic needs.
Keywords: IMS, Learning Tools Interoperability, LTI, learning application, innovation, community of enquiry

Introduction

The learning and teaching ecosystem is constantly under review with recurring debates within Higher Education about the role and function of the virtual learning environment (VLE) in supporting blended and online learning (Littlejohn & Pegler, 2007; Garrison 2011). For example, this was one of the topics at the 2009 JISC CETIS conference (MacNeill, 2009) at which different models for distributed learning environments were discussed. Subsequently these were summarised in a briefing paper (MacNeill & Kraan, 2010) under the headings of:

1. system in the cloud, many outlets;
2. plug-in to VLEs;
3. many widgets from the web into one widget container;
4. many providers and many clients;
5. both a provider and a client.

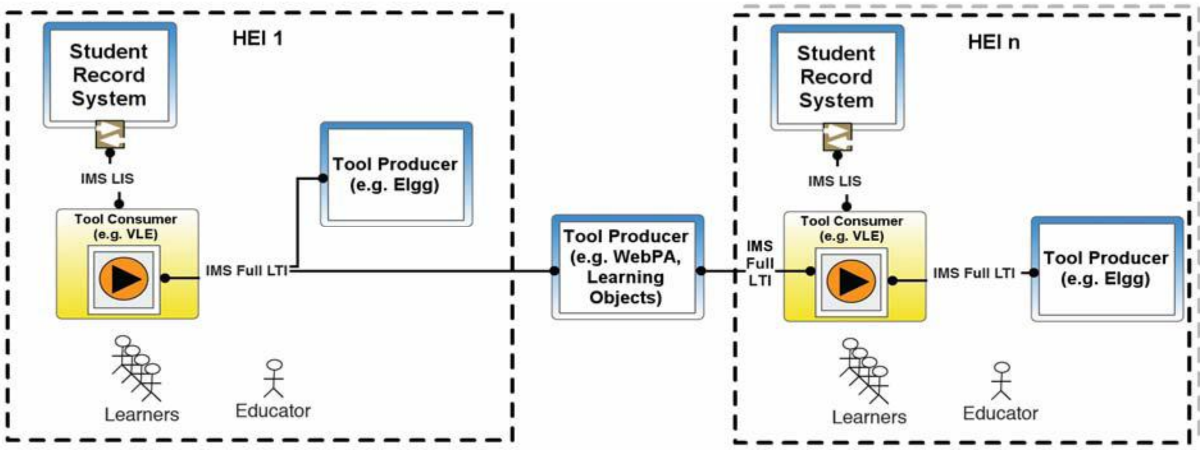

Figure 1: Enhanced "plug-in to VLEs" learning environment model

The common theme was a recognition that a VLE is not the sole source of applications used for teaching and learning; a complete view of a learning environment involves some form of integration of disparate learning applications. This paper outlines a variation on model 2 which retains a central hub (such as a VLE) from which connections can be made to other applications, both ones hosted internally by an institution (such as Elgg in Figure 1) and externally hosted, shared services (such as WebPA in Figure 1).

Teachers value a secure, central single point of entry into an on-line learning environment which enables students to move seamlessly between learning activities regardless of where the applications may be physically located (within or outwith the institution). Such deep integration allows the tutor to focus on the pedagogical design and organisation of a learning environment leading to the development of both social and cognitive presence (Garrison 2011). Unfortunately when trying to blend a range of applications to develop a challenging learning environment, tutors too often find themselves faced with a range of "labels and artificial standards" which limit their experimentation with learning technology (Garrison 2011, p76). The IMS Learning Tools Interoperability (LTI) specification has the potential to remove these limitations by:

- providing a quick and easy mechanism by which additional learning applications can be made available to learners and tutors;
- supporting the movement of data between systems;
- extending collaboration to include learners outside the institution.

This should enable the tutor to focus on supporting learners in meeting the educational outcomes of a programme of study rather than worrying about how students log into online learning environments and move between disparate applications.

IMS Learning Tools Interoperability

The IMS Learning Tools Interoperability (LTI) specification (IMS Global Learning Consortium, 2011b) is designed to provide a standard mechanism for connecting a learning application (referred to as a tool provider) to a central hub such as a VLE (referred to as a tool consumer). The implementation of LTI in an institutional learning environment is illustrated in Figure 2.

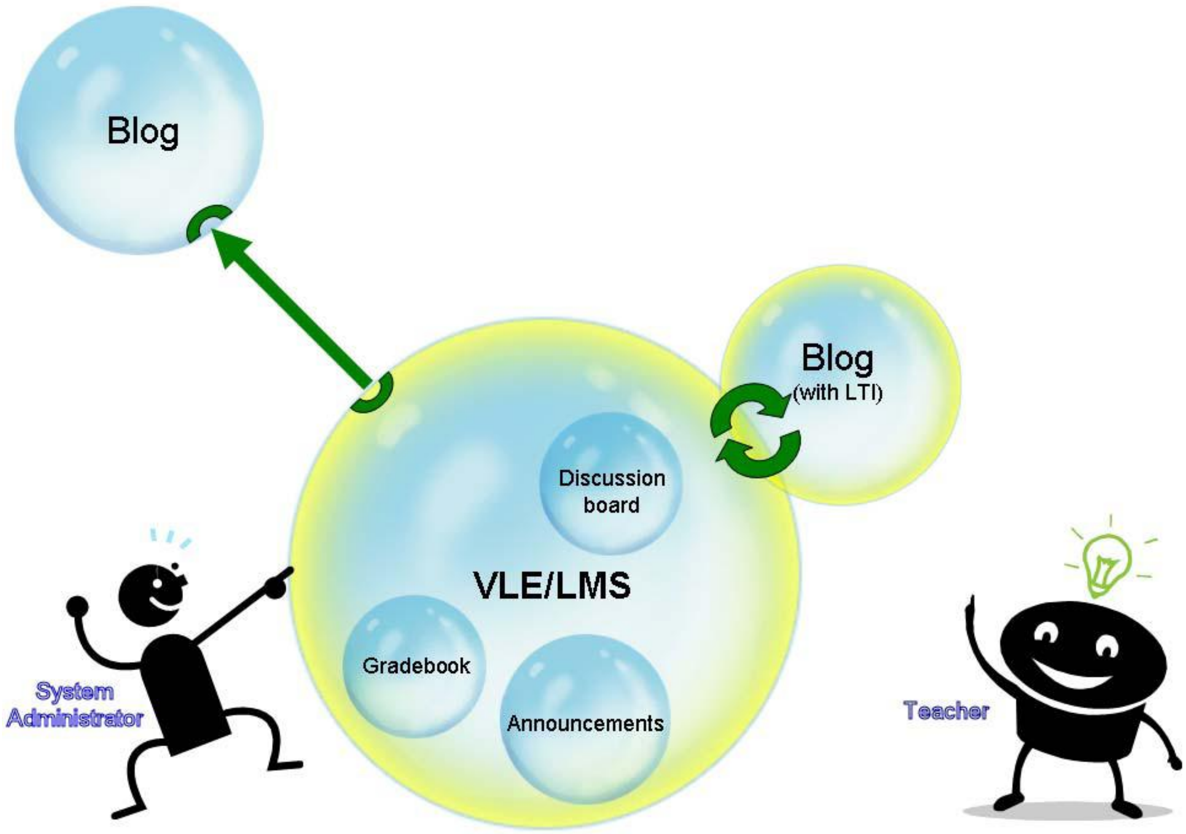

Figure 2: A visual representation of the implementation of LTI

A VLE comprises numerous core applications such as a gradebook, an announcements system and a discussion board. However, by its nature, the VLE will never provide *all* the learning applications demanded by teachers. Traditionally an external blog service, for example, might have been integrated with the VLE by writing custom code at both ends to enable users to launch the blog from within the VLE. Whilst such an approach has commonly been used, it relies on appropriate access to each system and the required developer expertise. The Basic LTI specification released in 2010 implements this form of "launch" (one-way) connection in a standard way such that any tool provider supporting Basic LTI can be connected to any tool consumer which supports Basic LTI. Basic LTI is already supported by all the major VLEs as well as many other learning systems (such as Campus Pack or PebblePad). Severance (2010) and Severance, Hanss & Hardin (2010) provide interesting use case examples of applications of LTI.

The Full LTI specification (not released at the time of writing) extends the design to provide a tighter, two-way integration between tool consumers and tool providers. This allows an external tool to exchange data with the tool consumer (such as enrolments and grades). It also provides a mechanism by which the tool provider is notified of relevant actions undertaken by users within the tool consumer (such as copying a course). In this way an external tool can closely resemble the behaviour of a tool embedded within the VLE and minimise the impact on users.

Impact of Learning Tools Interoperability

Developing a Community of Inquiry

Over the last decade, the community of inquiry conceptual framework has emerged which supports the planning and design of online learning in higher education (Garrison 2011) Drawing heavily on emergent research into online and blended learning and strongly influenced by the work of Dewey, this framework proposes that an online community of inquiry will support learners to develop appropriate skills and knowledge to become creative and critical thinkers. A community of inquiry is:

> a group of individuals who collaboratively engage in purposeful critical discourse and reflection to construct personal meaning and confirm mutual understanding. (Garrison 2011, p. 15)

Three interlocking elements are essential for the development of an online community of enquiry: social, cognitive and teaching presence. The IMS LTI specification supports the development of each of these linked elements by providing a toolbox from which tutors can select appropriate applications to create a seamless learning environment.. For example, a tutor may select:

- *on-line discussions* within a VLE to be used as a trigger activity focussing students on a specific problem but also informing tutors about their learners' current conceptual understandings or misunderstanding of the subject area; such an activity allows learners to develop a connection with the course and fellow students, thereby developing personal and affective relationships;
- *blogs* (outwith the VLE) provide an ideal reflective tool for critical thinking and personal meaning making;
- a *wiki* (within the VLE): an ideal area for learners to explore a specific topic, gather a range of materials and start to develop group meaning;
- *online synchronous tools* within a VLE allowing groups to present their developing ideas in the wiki which can challenged and probed by the Community;
- an *ePortfolio* outwith the VLE provides an individual summative assessment tool.

The adoption of LTI simplifies the process of selecting and implementing new learning applications for tutors. Instead of worrying about if such applications can be used in combination, tutors can focus on designing and maintaining an engaging and stimulating learning environment which facilitates critical discourse and leads to personal meaning making.

Benefits for technologists

The IMS LTI specification also provides benefits to all those involved in delivering online learning experiences to learners including:

- system administrators;
- learning technologists;
- application developers.

Impact on system administrators

Some VLE implementations of Basic LTI (such as Blackboard Learn 9.1) enable teachers to add their own connections to LTI-compliant applications reducing the workload for system administrators although diligence checks on the service provider and data security tests are still required. However, since LTI can be used for both internally-hosted and externally-hosted applications, it can provide institutions with a convenient mechanism for implementing their own developments as well as those from third parties. Furthermore, "Full" LTI provides support for administrative operations such as backing up, copying and restoring courses where the data relating to these courses may be spread across multiple systems.

Impact on learning technologists

Supporting a diverse range of learning applications which do not interconnect gives rise to pedagogical and technical challenges for learning technologists. Disparate systems require significant amounts of support to ensure that learners and tutors know how and where to access such applications in a timely fashion. This distracts from the pedagogical support that learning technologists can provide to academic colleagues and furthermore inhibits tutor innovation in developing an holistic learning environment.

Impact on application developers

The main benefit for developers is that adding support for LTI will enable their application to be integrated with a wide range of VLEs and other systems. This removes the need to create and maintain individual integrations for each VLE, such as a Moodle module, a WebCT PowerLink and a Blackboard Building Block. This does not prohibit a tighter integration from being written for specific VLEs where customer demand warrants the investment.

Conclusion

The adoption of LTI truly delivers benefits to all parties involved in delivering engaging on-line learning experiences to learners. Teachers should find it easier to locate applications which they can use in a seamless manner; the effort required by system administrators to check and deploy a connection to an external learning

application is significantly reduced, thereby increasing their ability to support more of the applications demanded by users; and developers can make their applications more widely available through a single integration. The use of LTI makes it more feasible for staff to innovate in their teaching and learning practices and for successful experiments to be deployed more widely across the institution.
The number of applications and systems which have already demonstrated conformance to the Basic LTI specification (IMS Global Learning Consortium, 2011a) suggests that there is widespread appreciation of the benefits to be derived. Continuing the trend of increased adoption merely serves to increase the benefits being delivered to the education community.

Abstract and Symposium Plan

This interactive symposium will examine the iPad as a pedagogical tool and will explore its potential to transform higher education. 'Padagogy', and 'Podagogy' are swiftly becoming mainstream terms. Whilst this symposium will focus primarily on the role of the iPad in the classroom it will also make reference to other personal computing and mobile devices available to learners.

The symposium will be conducted face to face and via webinar, with input from remote presenters and involvement from (selected) remote participants. ASCILITE delegates and outside participants will be able to comment via a twitter stream, which will be displayed at the venue, and will be able to collaborate more extensively via an ASCILITE wiki.

The symposium will be run as a panel session. Each of the representatives from the three institutions will provide an initial five-minute overview of their experiences in using iPads as teaching & learning devices, exploring the pedagogical opportunities, challenges and risks that iPads and mobile devices present. Immediately following each presentation there will be opportunity for the audience to ask questions and/or make comment. At the end of the panel presentations, delegates, virtual participants and the panel members will have further opportunity to engage in broad ranging exchanges about the value and uses of mobile learning devices and where their future might lead. This dialogue will be transcribed live onto a collaborative site which will remain available for ongoing deliberation at the end of the session. The symposium will be podcast for future online dialogue through the ASCILITE 2011 website.

As stated all delegates at the conference can attend face to face or virtually via webinar and can use mobile devices to *tweet* synchronously or asynchronously to #heipad during and after the symposium. The symposium is intended to encourage dialogue on Padagogy/iPad-eology and/ or i-Devices in higher education during and beyond the conference, as an ongoing collaborative iPad -Communities of Practice and/or Moot. It is anticipated that the symposium will generate interest in the development of a **multi-site research space** – a so called iPad research *blogosphere* – of related sites for ongoing collaboration after the symposium.

Microblogging- Twitter

Tweeting has begun:

...Getting ready for @ascilite11 with a panel on iPads in Australian higher ed, look for #heipad in Dec!

Uniting on-campus and distributed learners through media-rich synchronous tools: A national project

Charles Sturt University

Twenty-first century university students find it increasingly difficult to commit to regular face-to-face classes, yet real-time interaction and collaboration are often essential to achieving successful learning outcomes. This paper outlines the authors' plans for a cross-institutional project funded by the Australian Learning and Teaching Council aimed at identifying, characterising and evaluating technology-enhanced ways of bringing together on-campus and geographically dispersed students and engaging them in media-rich collaborative learning experiences. The project will focus on three synchronous technologies: desktop video conferencing, web conferencing and 3D virtual worlds. The paper first presents the rationale for the project, along with the main outcomes envisaged. The project's focus and methodology are then described, before concluding with a call for expressions of interest from members of the ascilite community wishing to join a network of practitioners and/or participate in case-study implementations that will be supported, monitored and evaluated as part of the project.

Keywords: synchronous learning, rich media, multimodal learning, collaboration, affordances

Project rationale and outcomes

Recent research clearly indicates that Australian university students are coming on to university campuses less and are going online more to fulfil their learning needs (James, Krause & Jennings, 2010). As they increasingly need to juggle the competing demands of work, family and study, the ways in which they engage with their institutions is changing. The use of technology is playing a key role in this change. While most students still enrol to study on a centralised campus, their studies are supported through a range of online resources – lecture recordings, notes, readings, and so on – that make coming to campus more optional. As students choose more flexible study options and technology-based learning support becomes pervasive, the boundary between traditional campus-based and distance learning in higher education is becoming blurred (Dillenbourg, 2008).

Given the changing patterns of student engagement in higher education, the sector is more actively considering how technology can facilitate instructional and collaborative interactions between staff and students who are increasingly distributed and dislocated (Herrington, Herrington, Ferry & Olney, 2008; Lowe, Murray, Li & Lindsay, 2008; Smyth, Andrews, Bordujenko & Caladine, 2011). Higher educators recognise that in many disciplines, interactive activities often lie at the heart of effective, engaging learning experiences. These interactions take a variety of forms, such as: an individual student and tutor participating in a deep discussion about a tricky concept; pairs or small groups of students discussing problems or topics; whole-class discussions including facilitated question-and-answer sessions; or presentations delivered by students before their peers.

While enterprise Learning Management Systems (LMSs) have some ability to support instructional and collaborative interactions, such systems are routinely used for and suited to the provision of resources and asynchronous communication via tools such as discussion forums (Blin & Munro, 2008; Valcke, 2004). But media-rich synchronous technologies have emerged that may be used to greatly enhance the educational experiences of increasingly distributed university students. We have been successful in securing funding through an Australian Learning and Teaching (ALTC) Innovation and Development Grant for a national project that will explicitly consider how three of these technologies – video conferencing, web conferencing and 3D virtual worlds – can be best used to support effective collaborative and communicative activities that engage higher education students and teachers in real-time learning irrespective of their location. The main purposes of this paper are to promote awareness of the project in the ascilite community and to solicit interest in participating in both the project itself as well as the community of practice that it aims to foster.

In undertaking this research and development project we seek to achieve a series of important outcomes:

12. The establishment of a practitioner network comprising higher educators from across Australia with an interest in the use of media-rich real-time collaboration and communication tools for learning and teaching.
13. The development of a collection of case studies documenting six real instances of the design, development, implementation and evaluation of learning and teaching activities that employ media-rich real-time collaboration and communication tools, together with a cross-case evaluation.
14. The development of a publication containing:
    a. a collection of *learning design exemplars* expressed as reusable templates that encapsulate key pedagogical features and patterns;
    b. a *technology capability framework* that provides (i) a map of how the three general technologies being considered (video conferencing, web conferencing, 3D virtual worlds) can be used with particular types of collaborative and interactive learning tasks/activities, and (ii) a matrix of the capabilities and limitations of specific tools (e.g. Wimba Classroom, Adobe Connect, Skype) on particular dimensions (e.g. types of communication channels and interactions supported, degree of synchronicity, visibility of participants);
    c. a set of overarching *guidelines for practice* that will draw on (a) and (b) to help higher educators make informed decisions and choices when designing media-rich real-time collaborative and interactive learning activities.

The project will lead to a greater understanding of how media-rich real-time learning technologies can be most appropriately applied in a range of institutional and disciplinary contexts across the higher education sector. Moreover, as emerging collaborative technologies move into the mainstream, this project will increase the capacity of university staff to use them effectively in conjunction with pedagogically sound learning designs. This has the potential to significantly enhance the learning experiences of students across the sector.

Besides delivering practical value, the project will also leverage, build on and extend scholarly knowledge in a number of areas related to learning, teaching and technology. There is broad consensus among educational researchers about the positive effects of collaborative learning on achievement (see, for example, Jonassen, Lee, Yang & Laffey, 2005; Joseph & Payne, 2003; Slavin, 1995). A key component of the longstanding research agenda in Computer Supported Collaborative Learning (CSCL) has been a focus on the effective design and use of social technologies (Suthers, 2006). Understanding how the features or 'affordances' of these technologies affect learning processes in specific instances and then comparing results across cases makes it possible to determine those elements of technology design that are vital and distinguish them from those that are less crucial

(Dwyer & Suthers, 2005). A primary goal of this project, then, will be to find and share collections of affordances that support effective collaborative and communicative learning processes.

Project focus

The project will focus on ways in which three types of media-rich synchronous technologies can be effectively used to engage lecturers and students in real-time learning regardless of where they are situated. The three technologies being considered are:

- *Video conferencing* systems enable synchronous interaction between remote participants in which they exchange detailed audio-visual information. They have a long history of transmissive use in higher education, for example to allow learners in rural and isolated locations to ‘attend’ lectures at regional centres (e.g. Caladine, 2006) and to connect students with teachers based at different sites of multi-campus institutions. However, as bandwidth and hardware costs continue to fall such approaches may be especially useful for bidirectional exchange of high-fidelity multimedia information, and for allowing students to participate in campus-based classes from their own homes and workplaces.
- *Web conferencing* tools such as Adobe Connect, WebEx and Wimba Classroom allow a group of users to enter a shared virtual ‘room’ that supports synchronous interactions through a variety of modalities. Users can collaboratively author text, draw shared diagrams and vote on issues of common interest, working together in real time in an environment that enables them to focus directly on the task and materials at hand (see Bower, 2008, 2011). While web conferencing has typically been used to facilitate entirely online learning (for instance, see Chapman & Wiessner, 2008), this project will also explore its potential for bringing together face-to-face and remote learners in integrated collaborative learning experiences.
- *3D virtual worlds* allow users portrayed by an animated figure or ‘avatar’ to move around a synthetic environment and interact with other objects and users. Examples of popular virtual world platforms are Second Life, Active Worlds and OpenSim. Virtual worlds can be used to support collaborative and interactive learning by allowing real-time verbal and non-verbal interaction, fostering co-presence, and enabling immediate control of objects and artefacts (Andreas, Tsiatsos, Terzidou & Pomportsis, 2010; Dalgarno & Lee, 2010). They can also be used in conjunction with face-to-face classes to create ‘blended reality’ experiences (Bower, Cram & Groom, 2010).

These learning technologies differ from those commonly provided within a university LMS, in that they are able to provide an increased sense of *co-presence* among staff and students, offer new possibilities for *concept representation*, and depend on *collaboration* coordinated in real time. Human-computer interaction researchers (Clark & Brennan, 1991; Kraut, Fussell, Brennan & Siegel, 2002) have shown how the characteristics of media such as co-presence (people have a sense of ‘being there together’ in the environment), co-temporality (communication can be sent and received at the same time), visibility (people and artefacts can be seen) and tangibility (people and artefacts can be touched) can all impact on the utility and effectiveness of both face-to-face and computer-mediated interaction. In terms of concept representation, selecting the most appropriate modalities is critical because it influences the effectiveness with which meaning is shared (Kress, Jewitt, Ogborn & Tsatsarelis, 2001).

Moreover, collaborative and communicative technologies relate differently to different pedagogical strategies, discipline contexts and types of educational material or content and as such may have different collaborative overheads or ‘costs’ attached to them. For example, Neale, Carroll and Rosson (2004) use the term ‘process loss’ to describe the overhead incurred when attempting to coordinate a collaborative activity. They also define ‘distributed process loss’ as the amount of coordination required to manage the main activity of interest when collaborators are operating remotely. They argue that distributed process loss in technology-based environments is much more costly than in face-to-face contexts, “so costly, in fact, that groups often do not recover from its effects” (p. 117). In their study, they observed that when participants struggled to understand what their remote partners were doing and why, collaborative breakdowns resulted. It is thus essential for higher educators to not only understand which technologies to use to meet the intended learning requirements but also to develop efficient techno-pedagogical strategies for effectively implementing online synchronous learning.

Project methodology

The project will be conducted in four overlapping phases. Phase 1, which will run from October 2011 to March 2012, will involve documenting existing practice in the use of media-rich real-time collaboration tools for learning and teaching. This phase will entail surveying extant literature as well as higher educators in a range of disciplines to create of a bank of innovative practices in the area. Specifically, an online questionnaire will be administered to gather summary information and learning design descriptions from academics and educational designers already employing media-rich collaborative and communicative technologies. Respondents will also be invited to join a practitioner network.

Phase 2 will commence in February 2012 and conclude in June 2012. In this phase, the various learning and teaching activities from the collection of innovative practices assembled in Phase 1 will be systematically analysed to understand their learning design patterns and technological requirements, with a view to creating a technology capability framework. The salient features of collaborative learning designs and the capabilities of the technological tools used in each case will be distilled, characterised and drawn together in a framework to help higher educators make informed media/tool choices and design decisions. As the framework is being developed it will undergo peer review by practitioner network members.

Next, in Phase 3, six cases will be followed and investigated through participatory evaluation. This phase will run for approximately eight months, from June 2012 to January 2013. The cases will be selected with reference to the data gathered during the first phase as well as in consultation with members of the practitioner network. Planning and shaping of the implementations will occur in collaboration with participating staff to encourage renewal and enhancement of their existing practice. Ongoing evaluation and consultation will take place throughout the implementation so as to optimise outcomes for students and staff. In addition, a summative 'effectiveness' evaluation of the approach used in each case will be performed.

A central driver behind this project will be the goal of building a networked community of technology educators interested in media-rich synchronous tools, and as such the final phase (Phase 4 – January 2013 to September 2013) of the project will be dedicated to the dissemination of project outcomes and material across and beyond this network. The project's findings will be reported and shared through a website and publications that draw on the exemplar learning designs, technology capability framework, and the case studies and their evaluations. It is intended that these resources will contribute to the development of staff capability in the domain of media-rich synchronous learning, thereby engendering improvements to their practice and to the learning experiences of students. Through these activities, and with the support of organisations such as ascilite, we expect to be able to not only promote awareness and uptake of the project results and resources, but also to provide demonstrations of the synchronous learning approaches and strategies through webinars so that attendees may more easily apply them in their own practice.

The outcomes of the project will enable university teachers to better understand how important characteristics of synchronous technologies – types of presence, ways of representing information, and modes of collaboration – impact upon learning processes, so that they can more effectively meet the learning needs of their students. The project will build on existing literature, such as that emanating from recently completed ALTC projects focusing on video conferencing (Smyth et al., 2011) and video lectures (Gosper, Green, McNeill, Phillips, Preston & Woo, 2008), as well as other national initiatives (e.g. the DEHub virtual worlds scoping study – see Dalgarno, Lee, Carlson, Gregory & Tynan, 2011), by both widening the spectrum of media being examined and also more explicitly addressing how different tasks and technologies can be *practically* combined to support effective, location-independent real-time interaction among students. The project will also draw on research and literature in the area of reusable technology-enabled learning designs – see, for example, the products of the projects in this area sponsored by the Australian Universities Teaching Committee (AUTC, 2003) and the UK Joint Information Systems Committee (JISC, 2010). The integrated set of synchronous learning design patterns produced will provide the higher educators with concrete examples to support them in synchronously blending campus-based and online learning and teaching. Concurrently considering an array of tools that lend themselves to broader collaborative and representational possibilities will permit the derivation of more robust, pedagogically informed frameworks and principles for technology selection and use, that will readily support application across the sector as the technologies become more pervasive and accessible to students and staff.

Conclusion and call for participation

In this paper, we have discussed the rationale and intended outcomes as well as the methodology for a national project that seeks to investigate approaches for facilitating truly collaborative learning experiences among on-campus and distributed students through the use of media-rich synchronous technologies, with a particular focus on three representative technologies, namely desktop video conferencing, web conferencing and 3D virtual worlds. A key feature of the project is the formation of a network of practitioners, with whose help six case-study implementations will be identified, supported, monitored and evaluated. A technology capability framework and set of exemplar learning designs, along with practical guidelines for staff, will be generated, then trialled and refined as part of the case studies. These resources as well as interactive webinars will be practical outcomes of the project, from which members of the ascilite community will be able to benefit.

We would like to take this opportunity to issue a call for participation in the project, which can be at a number of levels. Firstly, Australian higher educators with an interest in the use of media-rich synchronous collaborative technologies for learning and teaching are invited to join the practitioner network, and may request further instructions on how to do this via email. Secondly, those who have experience and/or expertise in this area are asked to complete the online questionnaire, details of which will be made available through the ascilite mailing list and at the conference. Thirdly, expressions of interest are sought from those wishing to lead the implementation of a case study at their institution within their subject/teaching area.

An investigation into the use of emerging technologies to transform teaching and learning across differently positioned higher education institutions in South Africa[2]

Vivienne Bozalek[3]
Directorate of Teaching and Learning
University of the Western Cape

This paper reports on a project which was initiated in 2011 and which aims to learn more about emerging technologies in higher education in South Africa and their potential impact on enhancing learning in an inequitable educational landscape. This newly developed research project includes a team of researchers across eight differently placed South African HEIs and one international NGO (see footnote 1 for researchers in the team and their institutional affiliations). The paper elaborates on emerging technologies, the South African context, provides an overview of the rationale for the project and describes the research design for the project.

Keywords: Emerging Technologies, South African HEIs, transforming teaching and learning,

Introduction

This paper reports on a project which focuses specifically on *emerging technologies* which are being used in South African Higher Education to improve teaching and learning. Emerging technologies are defined as those technologies which are ‘likely to have a large impact on teaching, learning, or creative inquiry on college and university campuses within the next five years’ (Johnson et al. 2011, p.3). or those technologies which are on the rise (Johnson & Adams, 2011). According to The Technology Outlook for UK Tertiary Education 2011-

[2] Acknowledgements to the National Research Fund (NRF) in South Africa for providing funding to make this project possible

[3] The following researchers are involved with the project and are acknowledged for their contributions to this paper: Lucy Alexander (University of the Western Cape), Judy Backhouse (University of the Witwatersrand), JP Bosman (Stellenbosch University), Renée Coetzee (University of Fort Hare), Lorraine Fakude (University of the Western Cape), Daniela Gachago (Cape Peninsular University of Technology), Eunice Ivala (Cape Peninsular University of Technology), Igor Lesko (Open Courseware Consortium), Matete Madiba (University of Pretoria), Markus Mostert (Rhodes University), Dick Ngambi (University of Cape Town), Lynn Quinn (Rhodes University), Michael Rowe (University of the Western Cape), Kathy Watters (University of the Western Cape)

2016 Report by the New Media Consortium and JISC support centres in the UK, mobiles are likely to become used in mainstream educational settings globally, with cloud computing also becoming prevalent in the next year and game-based learning coming into prominence in the next two to three years. All three of these technologies are seen to have the potential to disrupt what is current teaching and learning practice in higher education institutions (HEIs).

Contextualisation of the project

The question of how to make higher education more inclusive has been a central concern internationally over the past two decades (Drakich, Taylor & Bankier, 1995). South African post-apartheid policy documents on education reflect this same concern, embracing values such as democracy, openness and a human rights approach to education (Department of Education, 2001). Despite these policy intentions, however, the South African higher education landscape is still affected by the historical inequities of past policies, and many students and Higher Education Institutions (HEIs), particularly the Historically Disadvantaged Institutions (HDIs) are affected by scarce resources, poverty and students' inadequate preparation for higher education as a result of inequities in the general education system in South Africa (MacDonald, 2006, Scott, Yeld & Hendry, 2009). Higher educators world-wide also tend to fall back on outmoded transmission practices in their teaching, which are out of sync with the informal learning experiences of students (Ramsden, 2011). Emerging technologies, if used appropriately, have been shown to enhance communication and critical thinking skills, develop lifelong learning behaviour and facilitate student engagement in ways that promote a deeper understanding of coursework (Henard, 2009). In addition to improving teaching and learning practices, providing access to the vast resources that are freely available online may benefit students who lack access to traditional forms of content e.g. textbooks.

This study is intended to contribute to a national understanding of what emerging technologies might contribute to the quality of teaching and learning in South Africa. More particularly this study focuses on how emerging technologies can be used for transforming teaching and learning interactions and paradigms in a diversity of Higher Education contexts, including resource-scarce situations.

Emerging technologies and social inclusion

Emerging technologies can be used in innovative ways to address issues of inequity and social exclusion. These emerging technologies could be used to create seamless and safe embedded interactive learning spaces across diverse contexts (Davidson & Goldberg, 2009; DeViney & Lewis, 2006; Hakkarainen, 2009; Henschke, 2010; Looi, 2010; Sharples et. al., 2007; Traxler, 2009).

Traxler (2009) observes that less privileged individuals are able to access information of their choice using their own devices without needing to accept constraints and conditions historically imposed on them. The use of their own devices or ubiquitous technologies has the potential to improve educators' interaction with learners, learners interaction with content, and learners interaction with peers. Leveraging technologies that are available to people with emerging social practices enabled by technologies thus have the potential to bring about qualitative outcomes to education. The affordances of such integration are the blending of informal with formal learning. To the extent that blended learning could be viewed as empowering learners by widening access to education, the integration of blended and mobile learning has the potential to both widen access and enhance the learning experience. According to Van 'T Hooft (2009), mobility expands learning across space and time and opens many opportunities for learning that is neither sequential nor consistent.

Podcasts, blogs and e-books have been shown to be useful in resource-constrained contexts. Podcasts are seen as particularly useful because of their relative low cost and ease of use - Salmon and Nie (2008, p.3) refer to this as 'a high-value, low cost approach'. This is useful for students who come from impoverished backgrounds and who are not able to afford sophisticated electronic equipment. Many students however, do have access to mobile phones which also function as MP3 players. Salmon & Nie (2008, p. 5) have noted that the 'human and personal features of voices can convey to listener's a richer understanding'. Ng'ambi (2008; 2009) has noted how podcasts have been effective particularly for expansive learning with second-language students.

Blogs have also been successfully used in education to enhance and deepen learning and develop writing capabilities (Williamson, 2006). Quinn et al. (2007) point out that it is the connectivity between the writer and the reader that distinguishes blogs from ordinary paper based journaling practices, bringing the social aspects into learning. The ease and immediacy of the comment function on blogging could encourage the regularity and timeous feedback responses on the part of lecturers, tutors, supervisors and or peers.

E-books which are texts that are made available in electronic format on computers or handheld devices, have also been used in the South African Higher Education sector in a pilot project initiated by the International Association of Digital Publications (IADP) Affordable Access Project, a United Kingdom-based not-for-profit NGO. The main vision of this project has been to improve the education and effectiveness of students who will work in poor communities, particularly in rural areas including agricultural workers, nurses, social workers, teachers and doctors through providing affordable access to digital publications in the form of e-books. The aim of the IADP project has been to enhance education and address issues of poverty through providing affordable and convenient access to high quality, relevant content using digital technology. E-books are regarded as useful in that they are portable and mobile and do not occupy large amounts of space. For students who have to study in multiple environments they are accessible as long as hand held devices or desktop or laptop computers are available. However, in order to be used in a beneficial way, e-books need to be integrated into the curriculum and teaching and learning strategies (Kukulska-Hulme, 2005).

Research Design

This study follows a mixed-methods approach (Creswell, 2002), which includes quantitative and qualitative methods. It is envisioned that there will be two phases to the study - a national survey on the use of emerging technologies to improve teaching and learning in South African HEIs and a series of case studies on innovative teaching and learning practices in the eight HEIs that are part of the research team The project is funded by the National Research Fund in South Africa.

Overarching question

How could qualitative outcomes in education be realised by using emerging technologies to transform teaching and learning interactions and paradigms across higher education institutions in South Africa?

The sub-questions

In what ways are emerging technologies used in innovative pedagogical practices to transform teaching and learning across South African HEIs?

What can be learnt from an in-depth examination of case studies of innovative practice in a sample of HEIs in which these emergent technologies are being used?

What are the conscious and tacit theoretical assumptions guiding higher educators' teaching and learning practices?

What models of innovative theory and practice can be developed from the identification of transformative teaching and learning interactions and paradigms across the HEIs?

Data Collection Methods.

Phase 1 Survey of teaching and learning interactions using ICTs in SA HEIs
The survey has involved designing and prototyping a scoping questionnaire prior to administering this to academics in all HEIs in South Africa to establish current practices regarding emergent technologies to enhance teaching and learning. The online questionnaire comprises of closed and open ended questions. The objective of the survey will be to establish the contexts and conditions that frame current practices of use of emerging technologies within South Africans HEIs.

An online questionnaire was sent to lecturers at HEIs in South Africa who identify themselves as engaged in innovative pedagogical practices using emerging ICTs. The following questions were addressed in the online questionnaire to participants who self-identify as using emerging ICTs to enhance their teaching and learning practices:

The main qualitative questions were - What is the most innovative pedagogical practice that you used recently using ICTs (in the last two years)? What prompted you to initiate or use this pedagogical practice? (own motivation, addressing a specific problem; Please describe your teaching context in which you used this practice (level of programme, discipline, size of class, students' characteristics)? Which technology/tool did you use? Please describe? How did you come to use this specific technology? (eg heard from colleagues, from workshops, from students, from international conferences) ;What impact did it have on your teaching and the learning of your students? Did you use other technologies?

This survey will answer sub-question 1: In what ways are emerging technologies used in innovative pedagogical practices to transform teaching and learning across South African HEIs?

Phase 2: Institutional Case Studies
The team of co-investigators, collaborators and students would conduct in-depth case studies (at least one from each of the participating 7 institutions) of innovative pedagogical practices using emergent technologies to enhance teaching and learning in South African higher education, with particular emphasis on those that would be useful and affordable in resource scarce contexts.
These case studies will be used to answer the second and third research sub- questions: What can be learnt from an in-depth examination of case studies of innovative practice in a sample of HEIs in which these emergent technologies are being used? and What are the conscious and tacit theoretical assumptions guiding higher educators' teaching and learning practices?

Progress of the project thus far

The team has administered the questionnaire to HEIs and is in the process of analysing the data. The next phase of data collection will be case studies at the eight institutions involved in the study which will be started in 2012. There will be PhD students who will be pursuing their own projects using emerging technologies as case studies at these various institutions.

A framework for evaluating online learning in an ecology of sustainable innovation

George Bradford, Ben Kehrwald, and Stuart Dinmore
Learning and Teaching Unit
University of South Australia

In this session, a conceptualized framework is presented to provide an organization a tool by which to self-evaluate their online learning initiative. The tool is a methodology that leverages Ellis and Goodyear's framework, as well as leverages activity theory (Cole & Engeström, 1993), and a new categorization of online learning as described by Norberg, Dziuban, and Moskal (2011). The methodology is presented in sufficient detail to permit application to most any online learning implementation. A case study will be forthcoming, as this framework will be initiated in 2012 at the University of South Australia.

Keywords: Evaluation Framework, Ecology of Learning, Organization Self-Assessment, Online Learning.

Introduction

Ellis and Goodyear address the complex practice of "E-Learning," alternatively referred to as "learning online," "online learning," "blended learning," or "technology-enhanced learning" (TEL), within institutions of higher education, in an ecological frame. (In this paper, TEL is differentiated from online learning as the latter is used to specifically refer to LMS-type coordinated learning, and the former as referring to a wider variety of technology beyond the LMS orientation.) The argued need for an ecological perspective is rather self-evident: having the big picture view is necessary to best grapple with and manage the complexities of institutional practices, especially as individuals involved with the grappling and managing are likely caught between pressure to maintain flexible policy and to act aggressively, competitively. To understate, this is difficult work.

The need for such a framework is also self-evident. Organizations world-wide are adopting approaches to deliver teaching and learning using multiple modalities through the Internet. In the United States, 63% of institutions participating in a national survey administered and analyzed by the Babson Survey Research Group indicated they consider online instruction strategic for their institution (Allen & Seaman, 2010). The numbers say it best: in the United States, nearly one million more students are taking an online course in 2010 compared with 2009, and nearly 30% of all students take at least one course online. With consideration to this intensive shift in teaching and learning strategies, there is correspondingly considerable effort being invested in the development, implementation, and evaluation of programs to fulfill the goals of these online strategies. These institutions would find a framework to evaluate their organization's efforts to achieve sustained innovative practice very useful.

This concise paper will review activity theory, a new online learning model, and Ellis and Goodyear's work to suggest a framework for an organization's self evaluation of their TEL or online learning practices. The purpose of such a framework is to permit organizations a method by which they may examine their support for sustained innovation.

Activity Theory

The challenge implied with adequately describing the actors and the relationships is in recognizing the complexity of a social ecology. For this, a suitable model can be taken from Activity Theory.

The basic frame of the theory builds on a meditational triangle with subject, object and a medium (or artefact/tools) at the vertices (Cole & Engeström, 1993). Depicted in figure 1, the Activity Theory Model includes the following vertices moving in a clockwise rotation from mid-left: subject, mediating artefacts, object, division of labor (or the different roles that exercise an influence on the subject), community, and rules. This model at once sets the actor and target action (or behavior) within a frame of the key factors having influence on the actor and target action.

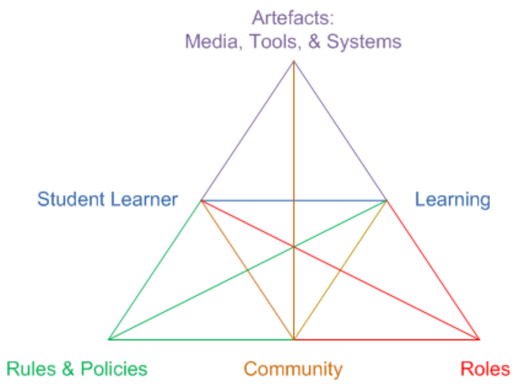

Figure 1: Activity Theory Model in context of the student learner in higher education.

Adjusting the model for a student in higher education, the student is the subject with learning as an object of active learning with an outcome target of new competencies. The influences on learning include the teachers, designers, tutors, administrators, and leaders (Roles) working to support the object target outcomes. Additionally, the student is a member of peers in the course(s) currently engaged, as well as study groups, or other clubs (Community). Naturally, course requirements, moral and ethical obligations associated with study and research, and institutional policies (Rules & Policies) also influence learning targets. Finally, activities will include mediators or tools to support learning (Artefacts), such as books, paper articles, audio and video source materials, and a myriad of technologies, such as learning management systems, both synchronous and asynchronous, and computer programs. It is arguable whether the pedagogy that orchestrates the use of mediators is part of the Artefacts, Rules and Policies, Community, or Roles since depending upon the details of the pedagogy, it could be a member of any of these vertices. In this article for simplicity, pedagogy can be considered a mediator for learning. The resulting model incorporates the key actors playing a role in student learning.

A Time-based Model for Online Learning

Blended learning more often describes teaching and course organization (Norberg, Dziuban, & Moskal, 2011; Oliver & Trigwell, 2005) and leaves for open discussion what "unblended learning" might be. Norberg et al. (2011) effectively argue against space being the key factor in learning as it always takes place where the student is. The more important factor is that the student and the components directing or influencing learning, such as the instructor, the places where students assemble to learn, etc, are orchestrated by time. As program and course directors adopt student-centred teaching models, an emphasis of *learning time* versus *teaching time* becomes necessary: given the increase of control over their learning, students progress in different ways and paces to advantage of their learning style preferences. The authors argue that "...as a result, learning space considerations might be deemphasized and replaced with time-related distinctions, building on synchronicity and asynchronicity, and focusing on a learning process" (Norberg et al., 2011, p. 12).

With this perspective, course structures can be examined by their synchronous and asynchronous blends of meetings and activities that can include technology enhancements (Norberg et al., 2011). Using this time-based approach, the authors identify five opportunities that influence the student experience. The five opportunities Norberg et al. (2011) identify are the following:

- Support – activities presented in a lecture that direct the student to conduct work beyond the lecture should be effectively supported using technology infrastructures, such as Learning Management Systems (LMS), blogs, drop-boxes, forums, twitter, etc. In an earlier time, the asynchronous work performed by students received minimal support.
- Migration – typical course designs tend to group activities as taking place during the meetings (i.e., synchronous sessions) or on the student's own time (i.e., asynchronous sessions). With a time-based model and leveraging TEL or online infrastructures, traditional course elements offer an opportunity to innovate: sessions can be translated from one format to another to better advantage of resource use, such as changing traditional lectures into recordings that are later discussed in detail.
- Synchronous location – traditional course designs tend to assume co-location as a requirement. However, co-location should be thought of as an opportunity for innovation: co-location should not always be a requirement of synchronous meetings, as ICT can be used to provide access to distant students (e.g., video and telephone conferencing, online chat, and online meetings).
- Flow – often the design effort of producing courses and programs keeps a strong emphasis on the alignment of objectives with assessments. This emphasis, while critical for effective instructional design, can reduce attention to the flow between instructional strategies. When learning activities are connected, whether they use synchronous or asynchronous modes, those connections must be supported to be effective (e.g., a prereading of text for a planned synchronous discussion will be dependent upon timely access to the material, or preparation to work with the material).
- Learner empowerment – students are most effective when they can access all course content anywhere and at anytime. Their social networks are useful when studying or for enhancing direction and guidance originating from synchronous meetings or interactions. Further, learner empowerment reflects a fundamental characteristic of effective learning: it's a means by which students take ownership.

With these five opportunities, an examination of TEL or online learning can be conducted regardless of mode. Further, the representation of these opportunities reflects learning more holistically than traditional approaches that tend to focus on teaching – the teaching elements are embedded into the full learning experience.

Ecology of Sustainable Innovation

Ellis and Goodyear (2010) take the completely reasonable position that avoidance of polarising thinking that yields indefensible contrasts, such as *new* versus *traditional*, *cognitive* versus *cultural*, or *technical* versus *human*, is best. The point is to bring focus to *relationships* rather than *differences* to better gain insight into problematic issues. Indeed, the concept of *ecology* is formed upon the relationships that comprise the system elements under study, in this case the sociological relationships inured to benefit students navigating TEL or online learning. From this approach, Ellis and Goodyear (2010) identify the key aspects of an ecology of learning as:

- <u>Balance</u> – given institutions' directive of teaching, research, and service, an ecological balance on learning can naturally "enfold" the three directives. The details surrounding how a learning balance would lead to a natural inclusion of teaching, research, and service cannot be stated in concrete terms, as the interpretation of balance will vary in different organizations. The point here is that *learning as the goal* would provide the perspective to find balance between the three.
- <u>Self-Awareness</u> – when parts of an organization do not each recognize their contribution or necessity to successful goal achievement, the organization as a whole is not *self-aware*. Further, there is an assumption here that suggests some level of awareness to the relationships the other parts carry into the organization. If the balance is on learning, then every part of the organization "...needs to be imbued with an understanding of 'good learning'" (Ellis & Goodyear, 2010, p. 20).
- <u>Feedback</u> – for the parts in an organization to recognize how well they are functioning, relative to the whole, they require feedback. Feedback acquired through systematic processes that communicate effectiveness of contributions creates opportunities for the organizational parts to learn. The origin of the feedback should be students, as well as internal and external stakeholders.
- <u>Self-Correction</u> – as organizations take action on feedback, they have opportunity for adjustment. Adjustments or self-corrections are re-alignments of operations to maintain a balance and focus on the organization's mission.

The four aspects above are inter-connected, inter-dependent, and to some extent heuristically related. But the aspects further demonstrate that an ecological perspective is good: insights gained through its adoption provide opportunities for sustainable innovation.

An Emerged Framework

The framework emerges from consideration of the three presented elements: activity theory set into context of a TEL or online learning support organization; a design model focused on the student experience that uses time, rather than place, as its guiding characteristic; and an ecological perspective taken on the organization that emphasizes sustainable innovation. Below, we identify each information source where data can be collected.

Organizational probes derived from the Activity Theory Model:

1. <u>External roles</u> that support learning environments (e.g., technology support assistants, instructional designers or teachers, teaching assistants or tutors, and the various leaders – team leads, directors, course coordinators, etc.)
2. <u>Internal roles</u> (i.e., those a student carries in the context of learning, such as first-year, group spokesperson, technical specialist, etc.)
3. <u>Community groups</u> supporting learning <u>with an external focus</u> (e.g., course or class peers, peers in different course or sections, or those who have previously completed the course (and may be available through different venues, such as clubs or forums), special tutoring groups, and technical help desk services)

4. Community groups supporting learning with an internal focus (e.g., students may belong to other groups that lie beyond the organization, such as religion or cultural heritage)
5. Rules that govern student behaviour that are often part of the rhetoric of university-related work, course and program requirements (e.g., use of Turnitin to control plagiarism, assignment due dates, assessments, etc.), and ethics originating from peers, family, or culture)
6. Artefacts or mediators that support learning (e.g., suite of technologies, systems, materials, and media – take heed: this item can become quite extensive)

To reduce data collection requirements, as well as analyses, it would be useful and advantageous to rank each within their respective areas (i.e., vertices) to identify major influences. The manner of ranking will naturally vary, but the approach to conduct the ranking should be stated and followed to permit future corrections. With the final inventory, further inquiry using a time-based model can be made, and later if problems or opportunities are uncovered, this inventory can be examined for sources of influence.

Experience from the student's perspective using a time-based model:

1. Take an inventory of all course or program activities and catalogue them as synchronous or asynchronous.
2. For all activities identified as asynchronous, identify the support strategies used, both overtly stated within course materials and those assumed a student will also have use of, that ensure student's successful completion.
3. For all activities identified as synchronous, identify any opportunities a course designer or teacher might use to change it from synchronous to asynchronous to improve focus on critical aspects of what is being learned.
4. For all synchronous activities, identify the rationale for a co-location requirement: does the design require attendance at a specific location, or are other alternatives a possibility? If all activities are mapped or drawn on a chart differentiating between synchronous and asynchronous events, examine the flow between each. What directions or other course elements support the student moving between the succession of activities: is there such a flow, and is there a natural progression that makes intuitive sense?
5. Finally, when examining the full list of activities, where and how is learner-empowerment integrated? Are students given options and choices? How much material or resources are available at anytime and from anyplace?

Following the collection of data previously described, varied analyses may be conducted to identify problems and opportunities of TEL or online courses, programs, and the organizations supporting their delivery. Such analyses serve dual purposes: one is to improve the student's experience that may influence learning outcomes, and the other is to serve as data for how well the organization functions to innovate on a sustained basis.

Ecological practice of TEL or online learning:

1. Conduct an inquiry into how the practice of balance is practiced within the organization. Is the mission of the organization focused primarily on learning? Is the practice of learning directing teaching, research, and service opportunities, and not the other way around?
2. Of the parts in the organization, do they recognize their contribution in the success of mission attainment as demonstrated in the learning analysis? How much does each part of the organization know of the other, and does each recognize the role they contribute to the learning analysis findings? How often do the parts coordinate and share information?
3. What feedback mechanisms are in place to provide the organization they are doing well or not? (For this, the source will originate from analysis using the previously discussed activity theory and the time-based model.) How believable is that feedback – is the information authentic and credible? How current is the feedback? Do opportunities exist to improve the periodicity of feedback, without degrading its authentic and credible nature?
4. How does the organization, the part of the organization or in its entirety, react to the information? How often are changes made? Where are changes being made to practice, policy, technology, communities, or roles? Does the organization react to correct a change in the balance from learning to the trinity of

higher education foci (i.e., teaching, research, and service)? How often does the organization examine their balance and foci of activities?

Conclusion

This paper presents a framework by which an organization supporting TEL or online learning might self-assess to determine their ability to innovate on a sustained basis. While no specific analytics are presented, the framework provides some examples of the type and nature of data to be collected. Analytics will be varied and will need to be fitted to the nature of data collected. A case study will be useful by providing details with the analytics that are specific to the situation under study that other organizations could follow and adjust as needed. Such an effort is the next step to this project. Further, the framework has additional uses: by leveraging an activity theory approach, the framework can be adapted for a variety of organizations. The requirement for such adaptations will necessitate different models to exemplify the targeted object, in the case of this paper, learning using the time-based model.

iWant does not equal iWill: Correlates of mobile learning with iPads, e-textbooks, BlackBoard Mobile Learn and a blended learning experience

Jeffrey Brand, Shelley Kinash, Trishita Mathew & Ron Kordyban
Bond University

This research tested the efficacy of a blended learning iteration with iPad tablet computers, an e-textbook and Blackboard's Mobile Learn application connected with a learning management system (LMS). Mobile learning was embedded into the pedagogical design of an undergraduate subject run in two semesters with 135 students. Using design-based research (DBR), an empirical investigation examined four variables including: iPad use; mobile technology use; attitude, including the unified theory of acceptance and use of technology (UTAUT) scale; and academic performance. Quantitative analysis with PASW Statistics included descriptive, scaling, correlations, partial correlations and ANCOVAs. Results suggested that students were positive about mobile learning, but were unconvinced that it made a difference to their learning. Performance variables demonstrated that age and self-managed learning attitudes were important covariates with academic success, and mobile learning per se was important but not independent from curriculum design and student engagement.

Keywords: mobile learning, higher education, e-textbook, learning management system, tablet computer, iPad.

Introduction and Literature

Much has been made of mobile learning and improved student experience and there is little question that the prospect of anytime, anywhere using small, yet powerful multi-purpose tablet computers is tantilising (Vavoula, Pachler, & Kukulska-Hulme, 2010; Guy, 2009; Kukulska-Hulme & Traxler, 2005). As with all new approaches to teaching and learning, the burden of proof must rest with the innovation, rather than the established approach. Yet, discourse on mobile learning and indeed, uses of emerging technologies in education more generally, readily presents assumptions about learning gains often based on observations of learner, teacher or administrator attitudes without testing the actual learning outcomes related to the technology use.

Belief in the legitimacy of the combined construct, mobile learning, is apparent in the literature including many educators claiming that student use of mobile technologies improves learning (Johnson, Levine, Smith & Stone, 2010). Mulholland's (2011) article, titled, *iPads strengthen education*, extolled the educational advantages of iPads, reported after a full year of use by school children in Chicago Public Schools. In the context of medical education, Sandars (2010) wrote that iPads "could revolutionise the way that we currently use technology to facilitate teaching and learning" (p. 270). Whereas mobile learning is "championed" in the literature, there is clear indication that there is a need to refine the pedagogy (Elias, 2011, p.144).

Consistent with preceding realms of educational technology, the literature establishes the affordances of the technology to a greater extent than evidenced learning outcomes. In other words, the articles establish potential and aspiration rather than actuals and results. Keskin and Metcalf (2011) assumed a link between the affordances of mobile devices and learning. "Mobile learning has come to people's attention because mobile devices are portable, ubiquitous, easily accessible and used by many people. This situation shows that there is great potential to enhance learning with mobile devices" (p. 202). Beetham and Sharpe (2007) privileged technology in their definition of mobile learning as technology driven, miniature and portable, andas facilitating connected classroom learning. Similarly, Motiwalla (2007) focussed on mobility and learner behaviour more than learning per se by observing that mobile devices liberate the learner with anywhere, anytime learning. Wang, Wu and Wang (2009) explained that mobile learning "content is received through wireless Internet and palm-sized computers, and thus m-learning usage can be considered to be a natural extension of computer use" (p. 99). Recognising that a one-to-one relationship between mobile devices and learning cannot be assumed, researchers are beginning to consider the characteristics of mobile learning that potentially make it a positive pedagogy (James, 2011).
Mobility is the term of choice used to connote untethered student experience with smart phones, tablets and netbooks, thereby making student materials light-weight and portable, and internet access allows students to access the content remotely using wireless networks. Writing in the context of English as a Foreign Language, Meurant (2010), for example, wrote that access to the iPad and wireless high-speed Internet connection has radically enhanced education.Such access, combined with germane learning tasks undoubtedly provide for learning opportunities in much the same way as other pedagogical processes are the repertoire of the constructivist educator, engaging the students in hands-on inquiry (David, Yin, & Chalon, 2009; Cavus & Uzuboylu, 2009; Motiwalla, 2007; Chao & Chen, 2009; Chen, Chang & Wang, 2008).

Discourse and research on mobile learning has mainly focused on the use of mobile phones (Johnson, Levine, Smith & Stone, 2010) and handheld computers such as the Palm operating system devices (Finn & Vandenham, 2004) as tools with which students access course content, if not produce work that produces learning outcomes.Kukulska-Hulme and Traxler (2005), for example, discussed the use of e-texts on Windows Mobile operating system phones and personal digital assistants (PDAs) in Open University courses. Their primary focus was on efficacy of mobile devices compared with established tethered personal computers in distance education systems that had relied heavily on internet connected PCs.In a similar vein, Liaw, Hatala and Huang (2010) researched attitudes toward mobile learning with surveys of n=152 university students. The researchers found that positive perceptions toward mobile learning increase when the curriculum is designed for autonomy to facilitate self-managed learning and is highly interactive. Cavus and Uzunboylu (2009) studied 41 undergraduate computer education students who answered attitude and critical thinking measures following use of mLearning devices. The authors questioned whether use of mobile devices promoted critical thinking and whether they had a measurable impact on student creativity, finding that student attitudes toward mobile learning improved significantly and critical thinking improved somewhat as use of mLearning devices increased. It should be acknowledged that the authors did not directly measure the critical thinking in terms of learning outcomes, but instead relied on indirect attitudinal questions of the students.

Chao and Chen (2009) designed an experiment to determine whether there were significant differences when students used paper-based versus mobile learning approaches to reading and note-taking. The researchers then elaborated on the experimental findings with an intensive case study. In their first study, 40 undergraduate students were randomly assigned to two groups of 20 each. The experimental group used mobile devices while the control group did not. In the second study, six participants participated in a follow-up case study in which their mobile learning tasks and device use were studied with system logs, diaries and interviews. The researchers found, unsurprisingly, that students used a blend of paper-based texts, personal computers and mobile devices for learning tasks. There was no significant difference in knowledge retention between the experimental and control groups.

This emerging body of mobile learning research attempts to explore a pedagogical link between mobility and learning, but provides limited empirical evidence that this connection has been established. This state of affairs is understandable inasmuch as research into mobile learning is "maturing" as no "explicit frame exists as yet to guide the choice of research methods and the tools for data analysis" (Pachler, 2009). Park (2011) **wrote that mobile learning is under-theorised . "Despite the many forms of and increasing services offered by mobile learning, it is still immature in terms of its technological limitations and pedagogical considerations" (p. 79).** The protean nature of mobile learning research, then, raises questions not only about its efficacy, but also about the constructs used in discourse about the phenomenon in university teaching and learning.

Even though mobile learning invokes notions of portable educational process, others have observed that the definition of mobile learning cannot be simplified into compounding the two terms (Guy, 2009). The side-by-side arrangement of the two words makes mobile the adverb of the verb learning. Learning connotes a more established or better-understood idea. For example, "learning is always the learning of some particular content" (Ramsden, 2003, p.49). To have learned means that a student has demonstrated a measured component of a set object or curricular domain and it is therefore baffling that mobile learning research has been centered around the feature of mobility as opposed to constructs of critical thinking and development of understanding (Laurillard, 2009).

Indeed, if learning takes place within the subjective experience of the learner, it is, to some extent, always mobile! The carriage of learning tools for decades, if not centuries, has been definitively a mobile process. Thus, while we focus on new tools, educators must also continue their focus on Ramsden's (2003) notion that learning takes place naturally and that the learning of a particular must necessarily be observed to claim the particular has been learnt, regardless of adjectival context of learning. In their examination of early mobile learning trials, Finn and Vandenham (2004) wrote, "while new technologies can offer new and creative modes of learning, the primary educational goals remain the same: to equip students with a set of skills and knowledges that will help prepare them for later life" (p. 32). Research into *learning* through ubiquitous educational technologies envelopes the concept of mobility, whereas research into *mobility* does not assure educators that the technologies are making a difference to *learning.*

In this context, much of the "buzz" around mobile learning appears to be a nascent and collective sense that students need mobile device skills that enable workplace productivity to ensure they have the professional capacity to use mobile tools effectively upon leaving the university education system. Debates about uses of computers and phones in the classroom in the short term may begin to centre on diminishing their use for non-academic and personal social networking and increasing their use for academic and productive use of mobile tools.

Mobile learning research may then re-situate the agenda on the operational definition of best practices in curriculum, pedagogy, teaching and learning (Kukulska-Hulme, & Traxler, 2005), rather than on its distinctiveness from other contexts of learning. In other words, mobile learning becomes nothing more and nothing less than good educational practice involving inquiry-based pedagogy with which students are engaging with real-world content in active processes that resemble those used by industry professionals (Jardine, Clifford & Friesen, 2008).

Moreover, focus on particular technologies is problematic not only in education but in almost any context as long as attention to them is situated in the now and the static rather than in the past, future and context and the dynamic nature of technological change. Early studies such as those cited above have defined mobile learning technologies in the context of the times in which the studies have taken place. As new technologies for mobile work emerge, studies are needed to assess not only the tool and the pedagogical context in which it may be used, but also the attitudes surrounding its adoption and subsequent use. This explains, to some extent, the focus on student attitudes in the literature on mobile learning.

Wang, Wu and Wang (2009) tested the unified theory of acceptance and use of technology (UTAUT) instrument, developed by Venkatesh, Morris, Davis and Davis (2003), with 330 students specifically in relation to mobile learning. The UTUAT is a multi-dimensional scale incorporating eight dimensions used in the field of information technology to assess user acceptance attitudes toward introduced technologies with a particular focus on workplaces. The model argues that acceptance of information technologies in organizations is an interplay between individual reactions to using those technologies, leading to intentions to use them and then having experience and use of said technologies. This model provides a powerful empirical tool with which to examine attitudes toward and use of mobile learning and other educational technologies to determine important correlates of use and subsequent learning or grade performance outcomes.

Wang, Wu and Wang (2009) provided a useful and concise summary of the detailed testing and attitude models tested extensively by Venkatesh and his colleagues.(2003) "UTAUT posits that performance expectancy, effort expectancy, social influence and facilitating conditions are determinants of behavioural intention or use behaviour, and that gender, age, experience and voluntariness of use have moderating effects in the acceptance of it" (pp. 95-96). Although the extensive literature and assumptions behind the UTUAT are beyond the scope of the present paper, it is worth defining the key scales and constructs that make up the UTAUT as provided by Venkatesh and his colleagues.

Performance expectancy is the "extent to which an individual believes that using an information system will help him or her to attain benefits in job performance" (Venkatesh, et al., 2003, p. 447). Effort expectancy is "the degree of ease associated with the use of the information system" (p. 450). Social influence is the extent to which a person perceives that important others believe he or she should use a new information system" (p. 451). "Attitude toward using technology is defined as an individual's overall affective reaction to using a system" (p. 455). Facilitating conditions are "the degree to which an individual believes that an organizational and technical infrastructure exists to support use of the system," (p. 453). Self-efficacy is the ability to garner one’s confidence, skills and abilities in order to accomplish a required task. Yang’s (2010) literature review and research led him to conclude “the level of consumer self-efficacy can predict individual consumer’s mobile data service adoption behavior” (p. 119). Anxiety is the evoking of "anxious or emotional reactions when it comes to performing a behavior" such as using a computer (p. 432). Behavioural intention to use the system, based on the Fishbein and Ajzen's (1975, cited in Venkatesh et al., 2003) theory of reasoned action is the self-reported intention to engage in a particular behaviour. In addition to these models, Venkatesh and colleagues argued that experience with a system, essentially the perceived or actual amount of time spent using it in the past, voluntariness of use or "the degree to which use of the innovation is perceived as being voluntary, or of free will (Moore and Benbasat (1996) in Venkatesh et al., 2003, p. 431), were critical variables in determining attitudes toward technologies.

Wang and colleagues (2009) noted that the UTAUT had been developed primarily from research completed in the context of workplaces and did not apply perfectly to the context of higher education and mobile learning in particular. They added to the scales used with UTAUT self-management of learning and playfulness and, in their study, chose not to include use behaviour, facilitating conditions, experience in using the technology system, or voluntariness of use but later wrote, "continued research is needed to investigate... behaviour, facilitating conditions and experience" in mobile learning (p. 113). Perceived playfulness was defined as "a state of mind that includes three dimensions: the extent to which the individual (1) perceives that his or her attention is focused on the interaction with the m-learning (i.e., concentration); (2) is curious during the interaction (i.e., curiosity); and (3) finds the interaction intrinsically enjoyable or interesting (i.e., enjoyment)" (p. 99). Self-management of learning was defined as "the extent to which an individual feels he or she is self-disciplined and can engage in autonomous learning" (p. 101).

Findings from the Wang, Wu and Wang (2009) study investigating the UTAUT in the context of mobile learning demonstrated that students’ intentions to use mobile learning tools were determined in large part by performance expectancy, effort expectancy, social influence, perceived playfulness, and self-management of learning variables. Moreover, they found that age moderated the influence that effort expectancy and social influence had on intentions to use mobile learning. While their goal was to apply the UTAUT to mobile learning, a simple way to extend this research would be to investigate the relationship between components of the UTAUT, perceived playfulness and self-management of learning on the one hand with actual use of mobile learning tools - particularly newly introduced tools - and actual academic performance as a proxy for learning.

The introduction of mainstream tablet computers over the past two years is rejuvenating and extending inquiry into mobile learning. That tablet computers have become more capable and therefore provide untested opportunities for mobile learning raises additional questions about what mobile learning means and how it works to enhance the experience of learners. The introduction of the Apple iPad in 2010, as well as the growth of applications or "apps" for the mobile technology ecosystem of the "iOS" or iPod, iPhone and iPad operating system may well be a part of such rejuvenation. Mainstream publishers of textbooks have begun producing apps for the iOS environment. In the absence of apps, publishers have produced ePub or Kindle formatted textbooks more easily read on tablets than on phones, but importantly compatible simultaneously with both pocket-sized and tablet-sized devices. Learning management system firms, similarly, have introduced applications beyond Internet browser interfaces with which students can access course content. In some ways, and for those with decades of experience in education, the rapidity and hyperbole surrounding mobile devices appears similar to that of the personal computer three decades earlier.

Such buzz reinforces ongoing questions about mobile learning not well answered by the literature to date. For example, to what extent are university students using mobile devices in their learning experience? Do students perceive that the use of mobile devices in their university education makes a difference to their learning? Do those students who use mobile tools demonstrate higher levels of learning, at least in terms of summary academic performance?

Research Questions

Based on the literature, and attending particularly to the need to establish an indication of the relationship between use of mobile learning technologies, attitudes toward their use (e.g., the UTAUT) and academic performance in relation to the latest available mobile learning tools, we sought to answer the following research questions.

1. What mobile learning technologies do students currently bring with them to the classroom?
2. What attitudes toward using mobile learning technologies are demonstrated particularly in relation to tablet computers, e-textbooks and LMS applications on mobile devices?
3. What is the observed relationship between use and attitudes of mobile learning tools and academic performance as a proxy for learning?

Methods

Mobile learning was embedded into the pedagogical design of an undergraduate subject run in two semesters with a total of 135 students. Using design-based research (DBR), an empirical investigation examined iPad use variables, mobile technology use variables, attitudinal variables including the unified theory of acceptance and use of technology (UTAUT) scale, and academic performance variables. Quantitative analysis with PASW Statistics included descriptive, scaling, correlations, partial correlations and ANCOVAs.

Research Design

Design-based research (DBR) was used for this study (Middleton, Gorar, Taylor & Bannan-Ritland, 2008; Wang & Hannafin, 2005). DBR allows a natural symbiosis between research and learning by evolving observation of students in a natural setting. In order to answer the research questions about students' behaviours, attitudes and learning, it was important that the research conditions did not interfere with the integrity of their phenomenology as undergraduate university students. The primary reason DBR was selected for this project was that instead of using artificial experimental contexts, students were volunteer research participants who spent no more time than normally spent engaged in class activities that were what they would ordinarily expect in a university classroom facilitated by their lecturer.

The pedagogical design of this subject was such that the educator used a combination of face-to-face teaching methods such as lecture and tutorial discussion and online methods such as immediate internet search and online formative assessment. Students were invited to use their own mobile devices such as netbooks, laptops, internet-enabled mobile phones and tablets to participate in the mobile learning components of the class.

The only novelty in the experience was that a loan scheme ensured all students had use of iPads pre-loaded with an electronic (e-pub) copy of their normally assigned textbook (converted for the study by the textbook publisher, Oxford University Press) and the Blackboard Mobile Learn application providing easy access to the learning management system (LMS). The iPad loan schedule allowed students to take home and use the device for a one-week period twice during the semester.

In keeping with the DBR method, student use of mobile devices had to be consistent with regular timeframes and locations (Wang & Hannafin, 2005). Use of mobile devices spans formal and informal settings (Sharples, 2009). Therefore, students had natural free reign with the mobile devices during the loan period. They were free to take them home and to load whatever applications they wished during the loan period.

Participants

A total of 135 students who were enrolled in an undergraduate subject titled *Digital Media and Society* in the final semester of 2010 and the first semester of 2011 participated in the study. To meet the requirements for ethics including self-determination, students were not coerced to participate, but were advised of the project through the LMS and a letter signed by the Chief Investigators (CIs) from an appointed postgraduate research assistant who coordinated the participant list and managed data de-identification. Although one CI was the academic responsible for the subject and marked most of the assessment items, a tutor was also involved in marking the minor assessment included in the dependent variable metric and the subject leader CI was blind to the volunteer participant list.

Measures

In total, almost 300 data points informed the measures for this research. As the key data collection instrument of the DBR process, students completed weekly formative and summative assessment tasks including end-of-lecture surveys and quizzes, four written essay assignments that were published as publicly available blogs on services such as WordPress and Blogger, and a podcast published in iTunesU with the students' permission upon completion of the semester. Students also completed an end-of-term final examination required by the University of survey-size major subjects. To answer the research questions, the weekly surveys provided demographics, behavioural and attitudinal data, and the quiz component (usually three questions) provided evidence of weekly knowledge gains. The lecturer has used these surveys for many years as a way to relate group demography and topical information about subject-domain drawn from students' own experiences and perspectives.

Overall subject scores were used as one general metric of learning performance. Students participated in one tutorial group discussion lasting 30 minutes the week following their use of the iPad; research from these sessions has been reported elsewhere and is not included in this report. However, students also completed a survey of their use of borrowed iPads and these results are discussed here.

The substantive measures from the unified theory of acceptance and use of technology, or UTAUT scale (Venkatesh, Morris, Davis and Davis, 2003; Wang, Wu and Wang, 2009), served as the survey questionnaire for the last lecture meeting of the semester. The modified form of UTAUT adapted by Wang and colleagues (2009) including wording related to mLearning was adapted for this research with scale results reported below.

Analyses

Data were analysed using mixed methods (Somekh & Lewin, 2005) for multiple facets of the project. The results reported here were analysed using PASW Statistics Version 18 on both Windows and MacOS computers and sought to include psychometrically valid reporting (Crocker & Algina, 1986; Marshall & Rossmann, 1989). Frequencies, means and similar descriptives were used for demographic and behavioural measures. Scaling analyses included Cronbach's Alpha analysis of the UTAUT subscales. Bivariate and partial correlations were used to assess the relationships among key demographic, behavioural, attitudinal and learning outcome measures and ANCOVAs were performed to assess the impact of iPad use on grades.

Results

Sample Description

Of the 135 undergraduate students who participated in the project, 63% were female. Modal age was 21 years (mean=22, range=19, standard deviation=3.9 years). Sixty percent were enrolled in the subject as required for their major or degree while 25% were enrolled for elective credit and 15% were study abroad students. The final grade distribution for these students was slightly skewed with 40% earning a *Pass*, 28% a *Credit*, 20% a *Distinction*, 7% a *Fail* and 5% a *High Distinction*.

Behavioural Self-reports on Technology Use at University

Use of the iPad was not compulsory and despite the opportunity to use the iPad during the semester, 36% of students decided not to borrow it, 54% borrowed it once and 10% borrowed it twice.

The first research question asked what mobile learning technologies do students currently bring with them to the classroom? The answer is that they come well equipped with a mixture of mobile and computing technologies and services, but tablet computers were in the early stages of adoption in late 2010 and early 2011.

Personal computer ownership among the sample was almost universal (98%) and most of these (92%) being laptops (13% reported using desktops with some indicating ownership of two computers); slightly more (54%) were running a version of the Mac operating system, 45% running a version of the Windows operating system and only one running a version of Linus. Notably, 83% said they also used computers provided in the university labs. Computer use throughout the day was reported by 63%, twice a day by 18%, once a day by 15% with the rest reporting less frequent use.

Almost all (96%) brought a mobile phone to class, and nearly half (48%) brought a laptop to class with only 4% of these being netbooks. Few (4%) brought a tablet computer to class. Mobile phones used by students were mostly Internet enabled (73%). Of those phones with either Wi-Fi or 3G or EDGE Internet access, students reported that 80% were primarily used for social networking, 75% for web browsing and 68% for email.

All but one student came to class stating that they were already subscribed with a Facebook account. Half had a Twitter account and one fifth had Linkedin accounts. Twitter was used throughout the semester with a unique hashtag to encourage community and student engagement. By the middle of the semester, 81% of students reported using it.

Use of mobile phones and laptops were evenly split during class time with half stating they regularly use their phones and half stating they regularly use their laptops. Of the students who stated they bring their laptops to class, half stated that primarily, they used the university's LMS, half that they use their laptops to take notes, half state that they go on Facebook, a third stated that they access Wikipedia. Of those who stated they regularly brought their mobile phone to class, a third reported texting at some stage during class.

Despite these tech-heavy frequencies among this sample of students, only 14% identified themselves as "power users" of information and communication technologies and 36% described themselves as tech-savvy. The majority (46%) said they were merely "tech-users." Tellingly, none self-identified with the label "tech-resister." Screens were used heavily for composing and reading, although e-books were preferred over printed books by few (11%) and only 26% had read an e-book over the course of the past year.

However, the iPad loan appeared to facilitate e-text reading and other productivity behaviours among those who borrowed it. For example, when asked whether they had completed any of the assigned readings from the e-textbook on the borrowed iPad in a given week, 66% said they had; further, 59% said they had completed readings that had been assigned from online resources using the loaned iPad. Late in the semester, when asked the question, “I grew to prefer the e-text over the print edition,” 30% disagreed, 22% neither agreed nor disagreed, but 48% agreed.

More students used the Blackboard Mobile Learn app with 77% indicating they had used it. Only 30% tried to use the iPad to take notes, but 76% used it for email and 88% for Facebook reading and 79% for Facebook status updates. Although invited to install apps, only 43% did so.

Attitudes About Mobile Learning Technologies

The second research question asked what attitudes toward using mobile learning technologies are demonstrated particularly in relation to tablet computers, e-textbooks and LMS applications on mobile devices. In short, although reported attitudes generally affirm Bond University’s policy to support mobile learning and tablet computing, analysis indicated there is little need to rush to satiate student demand.

A large majority of students feel there is benefit in blended learning with internet-connected devices used during class. Only 12% said there was “little benefit” or “no benefit at all” while 43% said there was “reasonable benefit” and 45% said there was “a lot of benefit” in their use. Nevertheless, when asked how much distraction results from using internet-connected devices during class, 27% said “a lot of distraction,” 37% said “reasonable distraction” and 36% indicated “a little” or “no distraction.” Asked whether the iPad motivated them to learn, 22% said it did not, 32% sat on the fence and 46% said it did. Similarly, 48% said the iPad “gave me an advantage in the classroom,” while 17% did not think so and the rest were neutral; 44% said the iPad “improved my study habits” while 21% did not think so and the rest were neutral.

Results of the UTAUT Scale

In general, the modified UTAUT instrument (Wang, Wu & Wang, 2009) provided subscale measures that held up to minimum standards of internal consistency (Table 1). Reliability estimates of the four-item subscales ranged from alpha=0.45 to 0.85. Cases were omitted where students did not complete the activity or in instances where one subscale item was not completed by a participant. These results included modest wording changes along the lines of Wang and colleagues (2009) and invoked reference to tablet computers in particular.

Table 1: Modified UTAUT Reliability Results

Subscale	Cronbach’s Alpha	Mean (7 = Max)	N of Items	N of Cases
Performance Expectancy	.85	4.6	4	105
Effort Expectancy	.80	5.5	4	105
Attitude Toward Using Technology	.85	4.9	4	105

Social Influence	.79	4.6	4	104
Self-efficacy	.57	4.9	4	105
Facilitating Conditions	.62	4.9	4	106
Anxiety	.63	3.8	4	105
Behavioural Intentions	.80	4.5	4	106
Self-managed Learning	.65	5.0	4	104
Perceived Playfulness	.45	4.4	4	104

Students in this study demonstrated a level of mobile and tablet technology self-assurance. Although effort expectancy is high, perceptions of both self-efficacy and university support (facilitating conditions) are similarly high while anxiety is relatively low. Nevertheless, students appear to be lukewarm about the performance gains they would expect from mobile learning in their blended learning environment and believe in their ability to self-manage their learning.

Relationships Among Key Variables

The third research question asked what is the observed relationship between use and attitudes of mobile learning tools and academic performance as a proxy for learning.

Bivariate Correlations

Bivariate correlations of the key demographic, behavioural, attitudinal and performance learning variables indicated on first inspection that age and self-management of learning are obvious important factors in mobile learning outcomes. So too are iPad borrowings and attitudes toward technologies and having a low level of anxiety or, in other words, self-assurance.Table 2 summarises these key relationships.

Table 2: Important Correlates of Mobile Learning with the iPad

	1	2	3	4	5	6	7	8	9	10	11	12	13
1. Age	1

* p < .05

Partial Correlations

Partial correlations of these relationships demonstrate the importance of state variable such as age. Controlling for age, the relationship between the number of iPad borrowings and grades is reduced to 0.18, falling short of significance. Thus, age is an important covariant in grade outcomes when considering the affordances of tablet mobile computing. However, controlling for self-managed learning, the relationship between grades and iPad borrowings increases the relationship between grades and borrowings to 0.32, $p<.001$. This curious outcome suggests multicolinearity between age and self-managed learning, not necessarily indicated by the bivariate correlation between the two measures. A partial correlation of iPad borrowing and grades, controlling for both age and self-managed learning drops the relationship back to 0.29, still a significant relationship.

ANCOVA Results

To further parse the relationship between iPad borrowing (which may have been none, once or twice) and grades, we submitted a series of models for a univariate ANOVA with age and self-managed learning as the covariates. The model we explored set = iPad borrowings (3 levels) as the independent variable, overall course grades as the dependent variable and age and self-managed learning as the covariates. The results indicated that when controlling for age and self-managed learning, those who used the iPad more, particularly those who borrowed it twice, also had the highest grades ($F=7.32$, $df=4,76$, $p<.001$).

Discussion and Conclusion

Research into mobile learning is exciting both for its student learning potential and as a newly emerging sub-domain in educational research. Because this nascent field is the focus of emerging literature, opportunity abounds for research to make a meaningful contribution. The conditions of the design-based research described here were such that 135 students enrolled across two semesters of an undergraduate class, were invited to borrow iPads for up to two one-week periods. On these iPads were tools related to knowledge domains tested at intervals and at the end of the semester and covered in formative assessment along the way. The three research questions drawn from the literature sought to examine the mobile learning tools students were using upon their arrival to the subject, their attitudes toward mobile learning, particularly with tablet computers such as the Apple iPad, and whether measurable learning gains as measured by overall grades could be observed as a result of exposure to a blended learning environment with tablet computers.

For the 135 students who participated in this research, it appears that the affordance of a new learning tool in a blended learning environment added modestly to their existing tool-chest of technologies and provided stimulus to achieve and warm, if not enthusiastic, attitudes toward the emerging mobile learning platform of the tablet computer, and added something to their performance. Indeed, it seems that those who borrowed the iPad twice had the highest grades after controlling for age and self-management of learning (both of which are positive correlates with grade performance).

There are other meaningful findings to be drawn from this research. That students in the age range of 18-40 have positive attitudes toward technologies as measured by the UTAUT subscale, and that age is positively correlated with attitudes toward technology is at first surprising. However, older, mature students, returning to university with purpose, represent a uniquely motivated and, perhaps, technologically savvy group of learners. The negative correlation between age and the anxiety subscale similarly indicates purpose and self-confidence with age at least up to the maximum age in this sample.

Also worth note is the usefulness of the UTAUT and the internal consistency among subscales. The findings are worthy of a separate paper and the contribution to the present analysis has been of great heuristic and generative value.

These findings are, as always, preliminary and should be treated with caution. On the face of it, the results seem to invoke notions of the Hawthorne effect in which a novel stimulus generates increased arousal and thus, for some, better performance. That those who borrowed the iPad had better grades, is perhaps indicative of the students' motivations and eagerness to learn, eagerness to use technology, and eagerness for innovation and engagement in the classroom. Certainly the results indicate that the ability to use Internet-connected technologies during class is important to students, particularly in a class on *Digital Media and Society*!

Challenging Perceptions of Blended Learning in an Adverse Learning Context

Des Breeze
College of Education,
University of Canterbury

Philippa Buckley
College of Education,
University of Canterbury

Fiona Gilmore
College of Education,
University of Canterbury

The Christchurch earthquakes of 22 February 2011 initiated an extraordinary process of professional development which informed and consolidated changes to the pedagogy and practices of three teacher educators. The fast-tracking of technical capacity led to a questioning of beliefs around effective tertiary teaching pedagogy. The resulting changes to blended learning practices enabled learning to continue during a time of natural disaster. This poster is of particular relevance to those involved in teaching in a blended learning context, focused on developing equitable online learning experiences that engage and motivate all learners.

Keywords: blended learning, tertiary teaching, professional development, pedagogy

Context

The University of Canterbury, College of Education has an established reputation for distance education and a tradition of offering open and blended tertiary programmes. In 2010 *Learn* (Moodle) was adopted as the University's learning management system. While the move to *Learn* is still very much in its early phase, implementation has been enhanced by staff's prior knowledge and experiences in blended learning and their willingness to engage with professional development opportunities. Across the institution, the use of *Learn* has varied. Some lecturers have taught courses entirely online and others have used the LMS to support face to face delivery. The three lecturers involved in this research had varied experience in distance and blended learning. All had attended workshop based professional development, consulted individually with an educational designer, and implemented an initial offering of their course.

On February 22 2011, the second day of the academic year, a 6.3 earthquake struck. Parts of eastern and central Christchurch were badly affected and the city's infrastructure severely compromised. Repercussions from this event, coupled with continuing aftershocks radically influenced the shape of the first semester course delivery. Our focus for 2011 had been to increase engagement with students on our respective *Learn* sites. However despite a forward looking approach, planning had not included the unforeseeable inability to provide on-campus students with traditional face to face delivery. We lost access to our physical resources including offices, materials and teaching rooms. On a personal level, we were living in a state of emergency, with limited access to amenities. On a professional level, we responded by reviewing and addressing of challenges of teaching our respective courses. The aftershocks continue. We face uncertainty as we grapple with challenges and tensions which continually force us to rethink our beliefs about tertiary teaching pedagogy.

Responsive pedagogy and practices

The context provided an 'opportunity' for us to produce and engage in an unplanned process of professional development. The need to rethink the blend of learning experiences offered via our *Learn* sites became apparent very quickly when we realised that all of our campus students were now effectively distance students. Our intuitive actions and responses, drawing on pedagogical understandings of what it means to teach, guide, and facilitate, have assisted in the transition campus teaching to an online context.

Methodology

We reflected collaboratively to identify how we made effective teaching decisions to ensure an equitable learning experience for all students. The processes which we collectively worked through replicated some of the indicators of evidence based effective professional development models which are relevant for initial teacher education contexts. The following represent a brief synopsis of our findings as we compared and contrasted narratives to identify emerging themes and patterns (Mutch, 2005). These have been analysed within a framework of effective professional development which included; engagement with existing beliefs, using iterative cycles of reflective discourse, regard for student viewpoint and voice, use of an inquiry framework, reviewing pedagogical decisions based on the theory-praxis nexus, and challenging understandings within communities of practice (Timperley, Wilson, Barrar & Fung, 2007).

Aspects of an equitable blended learning experience

The following represent blended learning practises that we embraced to support an equitable learning experience for campus students. We recognise that these practises could also enhance the learning experience of our distance students. These included:

- the presentation of online content in a manner that ensured engagement within a socio-cultural framework and which utilized a range of online teaching tools *(eg teaching within a study guide model, scaffolding using graphic organizers, Google Docs, modeling through the use of video clips, audio files, directed academic reading, diagrams, weblinks, drop boxes)*
- the scaffolding of students into blended learning *(eg a weekly structure containing a sequential 'books' structure, weekly 'News' notices, gradual release of content, use of audio files, consistent signposting through the use of text, colour, and icons)*
- the importance of an initial teacher presence and engagement to foster an effective learning community *(eg an introductory letter, responding to student posts in a timely manner)*
- ensuring course teachers were constantly aware of their roles and responsibilities in the virtual classroom. *(eg in the context of regular purposeful online interactions, timely responses to forums, letting go of the need to 'see' students, and being mindful of the importance of 'stepping back' to allow students to take responsibility for forum queries and discussion)*
- introducing, modeling, and leading the use of differentiated and asynchronous forums for a variety

of purposes *(eg one course had forums for purposes that included weekly discussion on course content, assessment tasks, and a book club, and another course had forums on developing personal content knowledge, and identifying online resources)*
- the development of tools and expectations which empowered students to take responsibility for their own learning. *(eg optional weekly webinars which provided direct interaction and dialogue about specific course content, and timed released of assessment, measured response to forum posts)*
- the establishment of a wider community of practice across disciplines enabling greater transparency and in-depth learning within a professional learning community.

A consequence of being forced to challenge the assumption that face to face delivery might be 'better' and more engaging from the learners' perspective, was to incorporate a wider range of online teaching tools which we had previously not used with the on-campus cohort.

Conclusions

On reflection, we were actively participating in a process of teacher inquiry, utilizing instructional design experts, and our own evidence based practice knowledge to support our new blend of teaching. This required a deliberate engagement with our pedagogical beliefs to ensure equity of experience across all delivery cohorts. Despite the 'reactiveness' of our response to this extreme situation, our actions, and subsequent reflection upon our actions, have contributed to significant and sustainable changes to the ways in which we teach, advantaging both the students and ourselves as effective tertiary educators.

Engaging in online postgraduate education as means of professional learning.

Tania Broadley PhD
Curtin Business School
Curtin University

With enrolments in higher education becoming a competitive market, through the removal of caps in 2012, the equitable access to postgraduate education is raised. Postgraduate education, provided through higher education institutions, is an important aspect of career development for professionals. Professionals working outside of the metropolitan area are increasingly seeking postgraduate education opportunities that will be delivered online, at a distance. In this research study, data collected from the teaching profession, has culminated in a model that will ultimately improve access to professional learning. This research paper aims to highlight the important role that higher education providers play in the delivery of postgraduate education to professionals working in regional and remote areas of Australia. Although this paper focuses on the realm of education, the model of connectedness, where synchronous and asynchronous technologies are used, can be adapted and applied to any profession that requires equitable access to professional learning.

Keywords: equitable access; regional and remote education; professional learning; online learning

Introduction

Professional learning for teachers in Australia must be considered in terms of the substantial changes and reform occurring in education. A number of Government strategies, including the Australian curriculum, digital revolution and transformation through national professional teaching standards, have been thrust upon teachers within this reform. Whilst teachers source professional learning through a range of opportunities, without doubt, enrolling in postgraduate courses are certainly a highly regarded option.

On a broader level, postgraduate education for all professionals working in regional and remote areas must be considered in terms of access and equity. The use of the internet and technology to engage and support professionals in learning opportunities is not new, however, many are still not utilising such approaches to their full potential.

In this paper, the author presents the importance of postgraduate education as a form of professional learning and the necessity to engage in using ICT to be able to provide equitable access to those who live outside of the metropolitan area. Further, a conceptual framework is presented, through the development of a model, where synchronous and asynchronous technologies support professional learning at a distance.

Background

A convincing body of evidence has been accumulated to indicate that the attraction and retention of human service professionals to regional, rural and remote areas both in Australia and internationally is a challenge (Herrington & Herrington, 2006; Human Rights and Equal Opportunity Commission, 2000; Miles, Marshall, Rolfe & Noonan, 2003; Pegg, 2007; Roberts, 2004; Wallace & Boylan, 2007). The link between retaining teachers in these areas and the importance of access to professional learning have been highlighted by a national study conducted by the National Centre of Science, ICT and Mathematics Education for Rural and Regional Australia (SiMERR). The research by SiMERR generated a report to the Department of Education, Science and Training (DEST) from which the recommendation "that education authorities, in partnership with schools and school communities, universities, and professional organisations meet the continuing needs of teachers in rural and regional areas through a range of strategies that ensure equitable access to ongoing quality professional learning" (Lyons, Cooksey, Panizzon, Parnell & Pegg, 2006, p. xiii). Inequitable access to professional learning was reported under the broader theme of professional connectedness and isolation. A substantial finding that "primary teachers in remote areas indicated a significantly higher unmet need for professional development opportunities such as mentoring, release time for professional development and collaboration with colleagues than teachers did elsewhere (Lyons et al., 2006, p. 85)", identifies the importance of further research to identify a framework for best utilising technology to support such an initiative.

In order to provide learning environments that offer flexibility required by higher education students, more higher education providers are turning toward the notion of e-learning. The use of asynchronous communication in distance learning is certainly not new, however, the idea of engaging students in a real-time environment to enhance their learning is less well documented.

The successes of online education (including K-12, undergraduate and postgraduate) where web conferencing and virtual classroom software considerably enhanced the learning experiences of external students has been documented in recent literature (Broadley & Pelliccione, 2010; Crump & Boylan, 2008; Crump, Twyford & Littler, 2008; Devlin, Feraud & Anderson, 2008; Lonie & Andrews, 2009). Further, Broadley and Pelliccione (2010) found that higher education students were enthusiastic about participating in collaborative, interactive, synchronous learning environments. The software used were real-time virtual classroom environments that allowed for communication through Voice over Internet Protocol (VoIP) and web conferencing, along with a large number of collaboration tools to engage learners. Students could access the online environment from any location that had a computer and an Internet connection either through physical cable or satellite connections. Broadley and Pellicione's (2010) study indicated that synchronous software provided a supportive environment through lecturer/student relationships, enhanced learning experiences and a positive impact on assessment that were not found in a purely asynchronous environment. A survey of the online students showed that 87.1% believed the synchronous software enhanced the quality of their online learning experience. Similarly, Lonie and Andrews' (2009) study found that web conferencing enhanced learning experiences of regional students and this learning approach provided an active learning experience that potentially reduced the discrepancy between regional and metropolitan student access to a collaborative learning environment.

Broadley and Pelliccione's (2010) work highlighted the role of synchronous technologies in undergraduate courses, however, it is important to note that higher education institutions are also providers of professional development for teachers in terms of postgraduate study. Lonie and Anderson's study (2009) supports the notion of postgraduate education courses being provided through these technologies. Teachers (60%) within Lonie and Anderson's study indicated the value of university postgraduate courses as a professional development opportunity and as a result the trial of synchronous software within Broadley and Pelliccione's study could inform the delivery of postgraduate units.

A study by Harvey (2005) in Queensland determined that career path and pedagogical content were motivating factors for teachers to undertake postgraduate study. Of the 178 respondents surveyed across five schools within this study, 15% were enrolled in postgraduate study. There is no evidence of whether these were regional or remote teachers; or if they were enrolled in a face to face or online medium. This was considered vital information in the context of the current study, to identify if access to higher education in the form of professional learning was reported as a significant factor for regional teachers.

In December 2008, Professor Denise Bradley AC delivered the Final Report into the Review of Australian Higher Education (Commonwealth of Australia, 2008). This report highlighted the importance of targeting under-represented groups currently accessing higher education including; those from low-socio economic backgrounds, regional and remote areas and Indigenous students. In order to increase participation the report states:

> An additional allocation of $80 million per year to develop innovative, collaborative, local solutions to provision of higher education in regional and remote areas is recommended. As well, serious consideration should be given to the development of a university with special expertise in provision of higher education across regional and remote Australia (Commonwealth of Australia, 2008).

An important recommendation essential to a more flexible and adaptable system of regional provision is found in Recommendation 16 indicating that “funding to develop innovative local solutions through a range of flexible and collaborative delivery arrangements in partnership with other providers such as TAFE” (Commonwealth of Australia, 2008, p. 112).

Similarly, further investigation into access of higher education was undertaken in 2009, as the Senate conducted a national Inquiry into Rural and Regional access to Secondary and Tertiary Education Opportunities (Commonwealth of Australia, 2009). A substantial number of submissions (n=759) from organisations and community members cemented the foundation of the need for equity and access to quality education programs. A seminal submission by the Society for the Provision of Education in Rural Australia outlined two significant points including the need for policy makers to apply a rural lens whilst developing education policy (Wallace & Boylan, 2007) and that secondly, sustainable rural communities are built on the foundation of a local delivered education to its youth (Society for the Provision of Education in Rural Australia, 2009). Further, this organisation acknowledged three main factors that impacted on non-metropolitan education; thus being distance, low socioeconomic status and aboriginality. Figure 1 exemplifies the connectedness between the three factors and illustrates the need for a holistic approach to address these challenges.

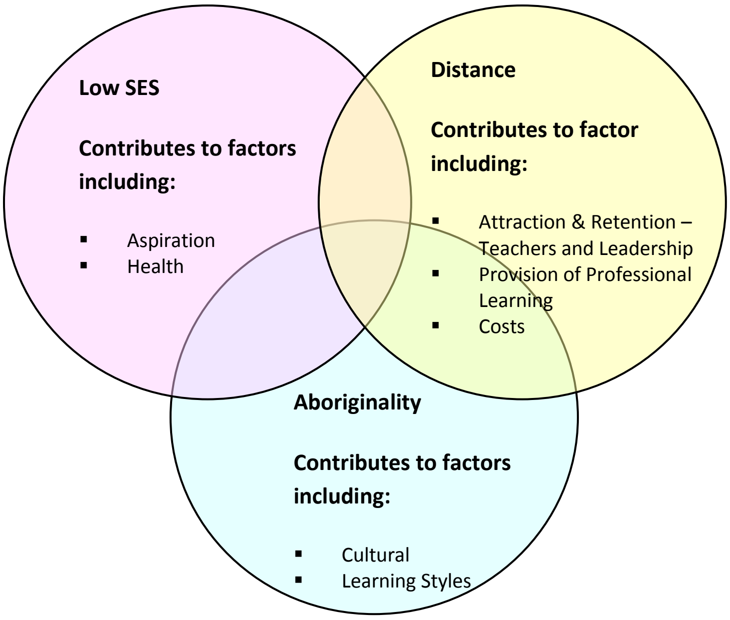

Figure 1: Significant factors contributing to educational disadvantage in rural and regional Australia (SPERA, 2009).

It is clear from recent literature in this area that many professionals working in regional and remote areas have limited access to professional learning opportunities within the higher education sector in the form of postgraduate study.

Method

This study incorporated three distinct phases. Phase One aimed to provide an extensive review of the literature in order to position this study in the context of the previous research and identify the gaps in the literature. Phase Two included two stages of data collection. In Stage One, quantitative data were collected through surveys to provide a general picture of the research problem, followed by qualitative data collected through interviews to further refine the general picture document regional and remote teachers' perceptions of their access to professional learning in Western Australia. Furthermore, in Stage Two of this phase, data were collected to describe current practice in the Department of Education and other professional learning providers in order to document the technologies currently available to support professional learning in an online environment. Phase Three included data analyses, findings and the formulation of a conceptual framework to facilitate the implementation of a professional learning community through the application of synchronous and asynchronous technologies.

A proportionate stratified random sampling of the regional (Country Teaching Program) and remote (Remote Teaching Service) teaching programs in the Department of Education (WA) was undertaken to ensure that a balanced proportion from both programs were surveyed. In 2009, at the time of the data collection, the total number of schools in each program were CTP schools (n=118) and RTS schools (n= 43). It was decided to include a total of 50 schools in the survey sample. In order to undertake a stratified sample of 50 schools over both programs, the sample consisted of 37 schools from the CTP and 13 schools from the RTS, all were a diverse range of size and district locality. Within the 37 CTP schools the sample allowed for a large number of teachers to respond to the survey, inviting a possible 549 teacher responses. From the 13 RTS schools, 169 teachers were invited to participate in the survey. Of these, almost 15% (n=106) of teachers responded to the survey. In situations where respondents returned the survey, but had not responded to the questions, frequency distributions of the data were undertaken to highlight these occurrences. Frequency distributions showed that two respondents had not answered any of the questions and as a result these surveys were removed from the final dataset. The final number of respondents for the survey sample was 104. A total of ten teachers were willing to participate in follow up interviews conducted by email, telephone and where possible, in person. Of these ten participants, four identified as classroom teachers and six were administrators in the role of principal or deputy principal within a school. Six participants were females and four were males. These teachers were employed in schools that ranged from employing a teaching staff of three to thirty staff. Experience working in a regional location ranged from four months to twenty years.

Results

A range of data collected, within this study, quantified the necessity for higher education institutions to consider their role in equitable delivery of postgraduate education to those living outside of the metropolitan area. These themes include: teachers working outside of their qualified area; professional learning valued by teachers and the access to technology in order to undertake online learning.

Teaching Outside Qualified Area

From the findings of this current study, it was evident that teachers working in regional areas were often required to work outside of the area they were originally qualified to teach. Additionally, they were required to teach a combination of differing levels of education within their position. For example, a primary trained teacher working in a small remote community school may be teaching a classroom that engages children from kindergarten through to Year 10. This has implications for teachers and their dynamic need for professional learning.

From the data, those qualified in Early Childhood Education (ECE) accounted for 13.5% (n=14), however 15.4% (n=16) indicated they were currently teaching in the Early Childhood field. This shows that two respondents working in Early Childhood were teaching outside of their qualified field or in a combination of ECE and another field. The Primary qualified respondents represent 57.7% (n=60) of the total participants. In contrast 40.4% (n=42) are currently teaching in Primary teaching positions. These data indicate that 18 teachers who were originally trained to teach in Primary positions are now teaching outside of their original area of qualification or in a position that requires them to teach over a combination of teaching positions. A total of 24% (n=25) reported being Secondary qualified teachers. Those currently teaching in Secondary positions accounted for 21.2% (n=22). From these data it is evident that three teachers who originally were Secondary qualified are now teaching in other roles. The remaining respondents from the original teaching qualification data comprise 4.8% (n=5) and reported their qualifications as Other. From the survey data it was found that Respondent 20 had a Bachelor of Education, Bachelor of Arts and Graduate Certificate in *Teachers of English to Speakers of Other Languages (TESOL) and was teaching Languages Other Than English (LOTE); Respondent 21 was originally trained as a special needs teacher and was now teaching K-12; Respondents 76 and 77 held a Graduate Diploma of Education and although they had trained in middle school education were now teaching primary and secondary; similarly Respondent 83 had a Graduate Diploma of Education and although trained in middle school education was now teaching in the primary years.* These data shows 6.7% (n=7) indicated their current teaching position as Other. After conducting further analysis of the surveys it was found that Respondents 20 and 21 had selected Other due to the reasons described above where their category was not clearly defined. Additionally, Respondents 25, 58, 65, 78 and 74 all reported they were currently teaching in positions other than ECE, Primary or Secondary, but did not provide further details to offer an explanation of what the current work involved. It is important to note that two teachers (1.9%) reported they were currently teaching a combination of ECE, Primary and Secondary areas. Similarly, 14.4% (n=15) of respondents indicated they were currently teaching a combination of two areas. A comparison of the respondents' original qualifications with their current teaching position is shown in Figure 2.

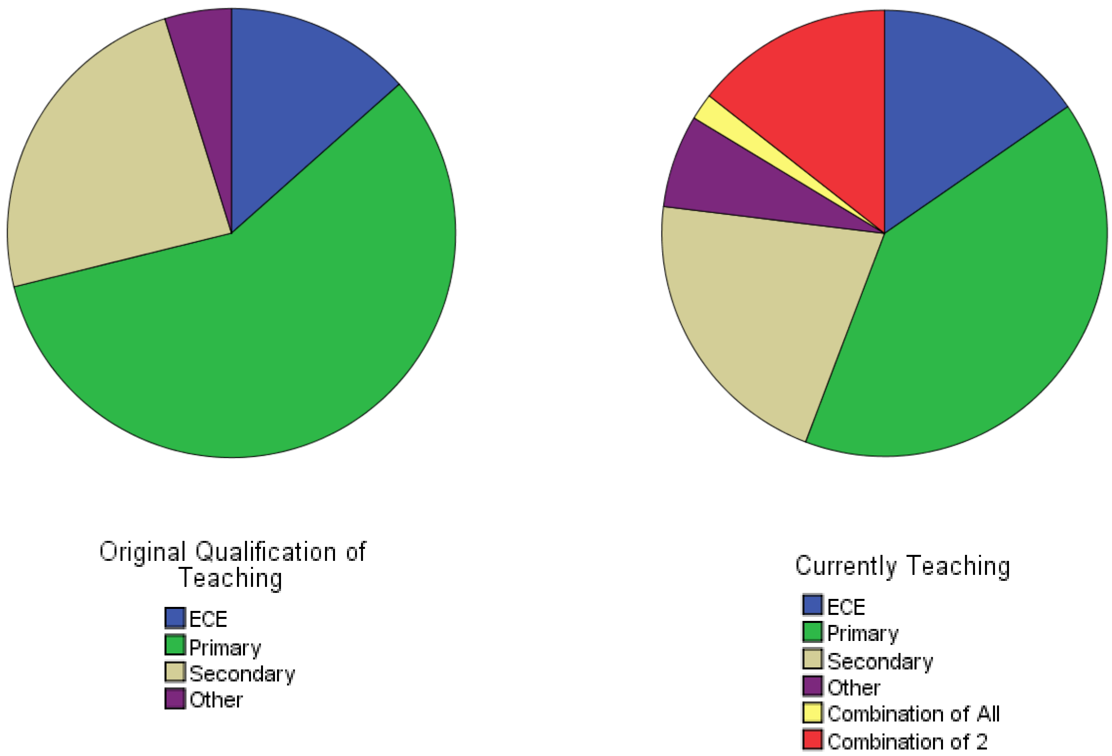

Figure 2: Comparison of original teaching qualification and current teaching position.

These data indicate there are teachers working outside of their qualified areas and as a result it is imperative they have access to professional learning to enable them to effectively implement an appropriate curriculum.

Professional Learning Valued by Teachers

Both informal and formal types of professional learning are undertaken by teachers. In terms of the types of professional learning valued by the participants within this study, university postgraduate courses were reported as the fourth highest mean (2.68) with 60% of participants selecting this form of professional learning to be regarded in high or very high value. Of some concern, reporting the lowest mean (2.22), 13.5% of participants in this study believed reading professional literature provided the least value in terms of professional development.

Table 1: Value of PD Approaches

	Little or no value	Moderate value	High value	Very high value		
Item	%	%	%	%	Mean	SD

Learning with and from your work colleagues including mentoring	0	14.4	43.3	42.3	3.28	0.70
Regional workshops	1.0	13.5	56.7	28.8	3.13	0.67
Conferences or involvement with professional associations	4.8	19.2	56.7	19.2	2.90	0.76
University postgraduate courses	5.0	35.0	47.0	13.0	2.68	0.76
DoE initiatives (ie, Graduate Teacher, Senior Teacher modules inc. face to face and online)	11.7	28.2	48.5	11.7	2.60	0.84
TAFE courses or other training organisations	8.0	38.0	50.0	4.0	2.50	0.70
Reading professional literature	13.5	53.8	29.8	2.9	2.22	0.71

Using ICT to Access Professional Learning

Participants in this study were surveyed as to their perceptions of using technology to access to professional learning. Videoconferencing technologies were underutilized with only 13.7% of participants having used such technology to access effective professional development. Similarly, only 11.1% of participants agreed that web conferencing software (such as a virtual classroom environment) is effective in accessing professional learning at a distance. Of importance to this paper, 75.8% of participants were uncertain about web-conferencing which might indicate the majority of participants in this study had not had the opportunity to experience learning through this technology. While 37.9% of participants believed that technology and ICT is assisting in the equitable access of professional learning for those working outside of the metropolitan area, just as many (36.9%) were uncertain this was the case. An important aspect of using any technology, particularly new technologies, is the support provided to users. Over half (55.4%), of participants in this study, indicated they had adequate support in their workplace that would allow them to feel confident in accessing professional learning in an online mode. Additionally, 70.8% reported they were confident and capable of accessing online professional learning if required. These data might indicate that attitudes and support for using technology to access professional learning are in place, however, opportunities that provide such an initiative have been limited for some professionals.

Table 2: Use of Technology/ICT

	Strongly Agree	Agree	Uncertain	Disagree	Strongly Disagree		
Item	%	%	%	%	%	Mean	SD
I have used videoconferencing for PD and this was effective.	6.3	7.4	38.9	31.6	15.8	3.43	1.05
Web conferencing software (such as Elluminate, Wimba,Webex, Centra7) is an effective way for teachers to access PD.	4.0	7.1	75.8	7.1	6.1	3.04	0.74

In my opinion, technology and ICT are making PD more accessible for regional teachers.	6.8	31.1	36.9	22.3	2.9	2.83	0.95
The support for ICT and technology is adequate within my school, so that I would feel confident to access online PD.	14.6	40.8	14.6	21.4	8.7	2.69	1.21
I am confident in using technology and am capable of accessing online PD if required.	29.1	41.7	10.7	15.5	2.9	2.21	1.12

The use of technology in order to access PD from regional and remote areas was also posed to participants through semi-structured interviews. While many could see potential uses of the technology and thought it may alleviate some of the access issues; there were issues posed by others with regard to costs associated with doing so:

> *Will be more accessible (T4).*

> *With budget restraints, it is an option but would still involve travel and accommodation as most small schools do not have the conferencing equipment needed (P2).*

Participants were questioned on how technology might affect the way that regional teachers access PD in the future. It was interesting to note how different teachers used the term technology. While some talked in more broad terms of technology, three discussed videoconferencing and one discussed the social networking site of Facebook. The use of videoconferencing and its effectiveness was posed:

> *With regard to video conferencing, we recently installed these facilities in our school (in the past 12 months). They have been used for one PD that I was a part of which was mandatory (child protection) (T1).*

> *Video conferencing was good while it worked but start-up time was impacted as the technology failed. There are time delays with speech which can be frustrating. As technology improves video conferencing will continue (T4).*

> *If you were using technology it would want to be video conferencing at this point in time. I don't think the online deliveries – you mentioned Elluminate before – and there's a range of them – I don't think that we in Australia have the bandwidth capacity to make them as good as they could be (P6).*

> *We have discussed what we're going to do in terms of hooking up via videolink for me because I have said that it's ridiculous that I'm travelling. We can do it, but we need to have from my end the infrastructure that we need. Whether its videoconference or through IP, I would do either (P5).*

Discussion

The need for professional learning for teachers in regional areas has been highlighted by a range of challenges. Findings from this study have provided evidence that teachers are being challenged to work outside of their qualified area, find it difficult to leave their school to attend professional development or undertake postgraduate courses, value postgraduate education as an effective form of professional learning and although uncertain about the use of virtual classrooms, many are confident with using technology. For regional and remote professionals to gain access to a range of postgraduate opportunities, technology offers the most convenient and affordable option to do so.

Additionally, technology offers a medium to connect professionals regardless of their geographical location. In line with the literature, the author proposes the concept of delivering professional learning and accessing professional learning from regional and remote areas be reconsidered. This research lies at the nexus of one key issue. Teachers as professionals must adopt a continuous cycle of improvement within their workplace and thus require a learning support network that underpins that cycle. In the case of regional and remote professionals, the only logistical possibility is to provide this through technology that offers synchronous and asynchronous communication.

The model in Figure 3 provides a conceptual framework for facilitating professional learning through an online learning community to deliver just-in-time (JIT) and individualised support to teachers in their local context. The teacher is the key element at the core of the model and understanding their individual professional needs is essential. In line with the findings, the second layer ensures the professional learning allows teachers to be situated in their local context; yet engage with other professionals within their schools, within their districts and across boundaries of districts. Ideally, a variety of learning opportunities would be made available that include just-in-time (JIT) support and meetings that are planned on a regular basis. For this to occur, the third layer of the model requires a vision from the principal at the school level to ensure the professional learning, although catering for teachers professional needs, is ultimately linked to the school priorities and the student needs within the individual school. The fourth layer of the model provides the technology that is available to support such an initiative. The use of both asynchronous and synchronous technologies is necessary to cater for those who prefer to collaborate and learn within a real-time environment. Those who are unable to join at specified times in the synchronous environment would access asynchronous communication tools. Building on the notion of situated practice and community cohesion, the outer layer of shared repertoire, mutual engagement and joint enterprise, teachers have access to a purposeful learning community where they can share practice, engage in collegiality and develop knowledge. It is envisaged the community be established by the need of the teachers and include other professionals that would value-add to the community. These professionals might include curriculum consultants from district or central offices, university lecturers in the specific field of expertise, industry experts if applicable to that field of expertise and others as required by the teachers within that community.

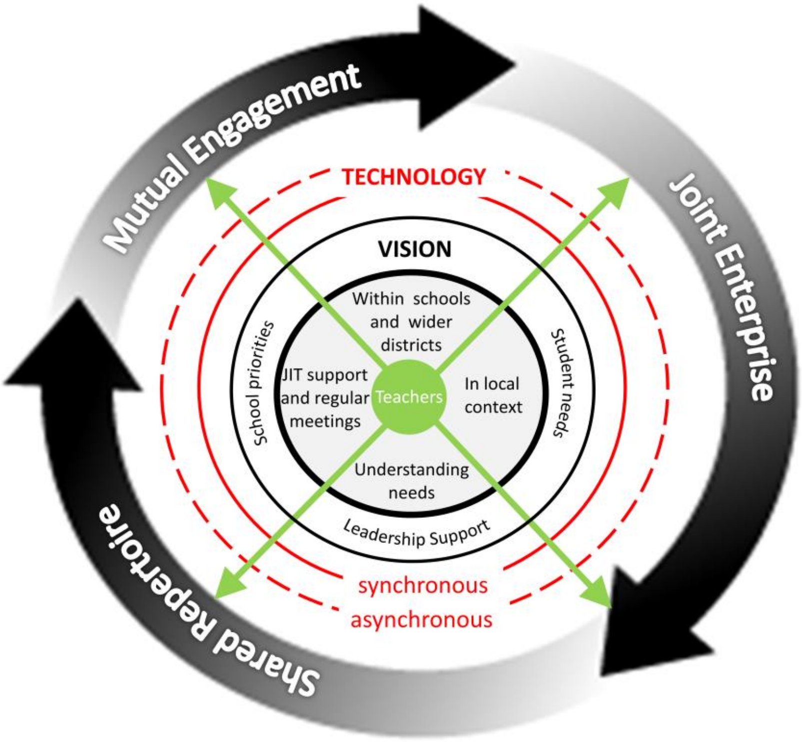

Figure 3: Rethinking connectedness model.

This model, constructed for the needs of teacher professional learning, can be applied to the realm of teachers or other professionals accessing postgraduate education at a distance. The use of asynchronous and synchronous technologies is highly beneficial for effective online teaching and learning.

Conclusion

Postgraduate degrees are a valued form of professional learning and as such, higher education providers need to ensure equitable access to all students regardless of geographical location. Through the application of a model, such as the *"Rethinking connectedness model"*, focusing on the needs of the individual and the vision of the organization within which they work, higher education providers can ensure that postgraduate education can be tailored to suit the requirements of professionals working in regional and remote areas of the nation.

This paper reports 'research in progress', which investigates the experiences of first-time distance learners with a strong phenomenological dimension. It takes place against a backdrop of challenges facing distance education in Australasia in which issues of recruitment, attrition (retention) and completion rates have come into sharp relief. This study will go beyond the current literature by producing a set of research-led deliverables that will enhance the supports and services available for first-time distance learners. The project is framed by an audit of initiatives designed to enhance the success of distance learners at two Australasian universities. The primary investigation gathered reflective video diaries from 20 first-time distance learners during Semester 2, 2011. The paper describes the methodological challenges of collecting learner stories through video and shares some of the preliminary qualitative data from this phase of the study.

Keywords: Distance education; learner engagement; reflective diary

Introduction

There is a wealth of literature exploring the individual, social and organizational factors which impact on student recruitment, attrition (retention) and completion rates in higher education. As Zepke and Leach (2007, p.237) observe, 'Improving retention rates in post-school education has become a focus for policy-makers and researchers throughout the western world'.

Student retention has been linked to learner engagement. There are three 'dimensions' of learner engagement that are used in educational research (Bull et al., 2010). The first is 'behavioural engagement', which is demonstrated by students who are involved and participating, meaning that they are likely to be on task and following instructions. The second is 'emotional engagement', which manifests as signs of interest / enjoyment and means that students find the learning sufficiently worthwhile / challenging to give it their attention and effort. Lastly, 'cognitive engagement' manifests at a surface level through a student's ability to describe what they have learned or to complete a task accurately. However, at a deeper level, a student who is cognitively engaged is likely to initiate self-directed investigation or setting and solving related challenges.

A number of Australasian studies have investigated learner engagement in tertiary education (James et al., 2009; Kift, 2009; AUSSE, 2010). In brief, we know from previous research that:

- The first year experience is critical to learner success and, during this time, institutions have the influence to enhance the student experience and, in turn, which students succeed (Kift, 2009);
- A high proportion of students consider dropping out of university in their first year. However, only a few indicators suggested that distance students were less engaged than on-campus students (AUSSE, 2010).
- More students than ever are studying by distance, which has been augmented by new digital technology. Students now expect technology to be a central feature of their learning experience (James et al, 2009).

Internationally, Simpson (2009) is one of the leading scholars whose work focuses on learner engagement and retention in the context of distance education. He claims there are many possible interventions available that have been known to successfully support the engagement and retention of distance learners. However, these interventions are often applied in a seemingly 'ad hoc' manner or what he describes as a 'goulash approach' to distance learning (Simpson, 2009). To overcome this problem, MacKay et al., (2010) adapted an 'intervention framework' for distance learners as part of a major externally funded project to enhance distance learner retention. The framework is based on a combination of the 'intervention pyramid' by Wilson (2009), which identifies the different needs of different learners; and on the student life-cycle published by the Higher Education Funding Council for England (2001).

Building on this work, the current research has been designed to answer the following question: What are the overarching principles for engaging students in distance learning and, to that end, which are the most effective intervention tools, supports and resources during the early stages of the study lifecycle?

Methods

First phase

The first phase involved an audit of initiatives designed to enhance the success of distance learners at two Australasian universities. The audit framework adopted the six stages of the study life cycle (HECFE, 2001; MacKay et al. 2010), against which initiatives were recorded:

1. Thinking about study – Initiatives that encourage a variety of people to participate in higher education by raising their aspirations, while helping them begin to understand the learning and teaching methods used;
2. Making choices, e.g. Tools that assist potential students actively gather information, which may help them self-assess their readiness, suitability and capacity for study via distance;
3. Enrolment – A well designed admissions process can not only help to reduce stress but also contribute to retention, as the student is better informed and more aware of the expectations within higher education;
4. First weeks – In addition to initiatives surrounding orientation, this stage incorporates retention and engagement strategies relating to the first 6 to 8 weeks of study via distance;
5. Progression – Initiatives that provide ongoing support for student success and review the appropriateness of teaching and learning approaches during and beyond the first semester;

6. Completion – Interventions that prepare students for life after their current distance paper(s), which may include strategies to support students as they make the transition to the working environment.

Second phase

The second phase adopted a mixed methodology with a strong phenomenological dimension. This meant that the experiences of learners were recorded from their own point of view using Sony bloggie™ video cameras for data collection . Approval to conduct the second phase of the project was granted by the University's Human Ethics Committee.

Recruitment
The recruitment of first-time distance learners was enabled by the Director of Student Management who granted the project permission to access enrolment data for students studying via distance for the first time in Semester 2, 2011. The primary method of recruitment was by email invitation from the Project Leader via inyourownwords@xxx.ac.nz to all potential participants at the point when their enrolment had been approved. For further information, the email invitation included a 'Participant Information Sheet' along with a link to a participant-facing website: http://inyourownwords.xxx.ac.nz. A notable feature of the website was a video introduction from the Project Leader and Project Manager using the same Sony bloggie™ video cameras that were provided to participants.

The Information Sheet explained that the greatest benefit of participation was likely to be the activity of self-reflection, which is known to enhance learning outcomes. In addition, it was highlighted that participant data will be disseminated across the distance education community to help improve the learning experience for future students. To compensate participants for their time, the Information Sheet explained that a token of our appreciation (koha) would be extended upon receipt of participants' final diary episodes.

Sampling
The recruitment campaign reached more than 750 potential participants, of which 140 first-time distance learners volunteered. The sampling process was based on the decision to select 20 participants who broadly represented the demographic and geographic diversity of distance learners. The profile of diversity was informed by a demographic analysis of the University's distance students during the 2010 academic year. Although more students volunteered, the funding and feasibility of the study restricted the sample size. Selection criteria included: age, gender, ethnicity, geographic location, subject of study, level of study, entry qualification, along with prior or current experience of tertiary study on-campus. Twenty successful volunteers received an email request to confirm their agreement to participate by signing a 'Consent Form'. Those 120 volunteers not selected received a transparent explanation.

Data collection
Upon receipt of signed Consent Forms participants were sent a Sony bloggie™ video camera via courier to their home address. Upon receipt of the bloggie™, participants received an orientation document via email, which was designed to support each participant in becoming sufficiently confident with technology to participate effectively, i.e. operating the camera then uploading and submitting data files. Those who required additional assistance were contacted by the Project Manager. As part of the orientation process, participants were asked to record a practice diary in response to some initial reflective questions.

Reflections were gathered using a video diary technique adapted from previous studies. Riddle and Arnold (2007) used the 'Day Experience Method' to investigate everyday life situations. They required participants to record written answers to specific questions sent at irregular intervals (between 30 and 90 minutes) between 8am and 10pm on three separate days. In contrast, Cashmore, Green and Scott (2010) adopted a free-form approach to video diaries in a longitudinal study with undergraduate students at the University of Leicester. The present study adopted an approach that struck a balance between a structured approach and free-form approach.

The initial expectation was for five minutes-worth of video footage per week; although this expectation waned given that the greater issue was not one of duration but 'forthcomingness' of information. Of the twenty participants, six presented some concern around their willingness and/or natural ability to reflect deeply on their distance learning experience. Simultaneously, three participants capable of speaking at length (>10 minutes per week) presented a challenge in the limited depth and breadth of their dialogue. The research team faced the challenge of accommodating diversity while maintaining enough consistency across participants to prevent the data becoming skewed. In response, a 'reflective prompt' protocol was designed to encourage 'free-flow' reflections whilst providing 'fish-hooks' to elicit targeted categories of information in a lightly structured manner. Within 48 hours of receiving a participant's video file, the Project Manager would respond via email with a set of reflective prompts, which were based on the following framework:

- What's on your mind at the moment?
- Fish-hooks for deep, strategic and surface learning indicators
- Fish-hook for support indicators
- Is there a word that sums-up your study this week?
- What's on your plate next week?
- Are there things you'd like to continue, start and/or stop?

Exceptional data was collected during the first half of Semester 2. During semester-break, participants were given the opportunity to continue or conclude their involvement in the project. Eight participants chose to conclude, while twelve chose to continue until the end of semester. The research team were mindful of any sense in which the students felt abandoned on conclusion of the study.

Data management
To mitigate any participant concerns about being identified via their video recordings, data was handled solely by the Project Manager. Upon conclusion, participants were given the opportunity to review their data before deciding whether to authorize its release for the purpose of academic dissemination. Participants were given the option to release a transcript of their data under and alias identity and withhold their video recordings.

Reporting data
Data analysis is scheduled to take place in November 2011. The analytic method will be thematic analysis, which is a method for identifying, analyzing and reporting themes within data. A theme captures something important about the data in relation to the research question, and represents some level of patterned response or meaning within the data set (Braun & Clarke, 2003). In this study, thematic analysis will follow a 'realist' method in which the experiences, meanings and the reality of participants are reported. An inductive approach ('bottom-up') will be applied, which means that themes will arise from the data. Thematic analysis follows a six-step process: Familiarization; Generating initial codes; Searching for themes; Reviewing themes; Defining and naming themes; Reporting content of themes (Braun & Clarke, 2003).

Third phase

An invitation to participate in an anonymous, online survey was extended to all 160 first-time distance learners who volunteered to participate in the second phase. The survey was not extended to the potential pool of 750+ first-time distance learners at the university because it was assumed that their preference not to participate was implicit in their rejection of the initial invitation to participate. The invitation was sent via email from the Project Leader and accompanied by an Information Sheet. Approval to conduct the online survey was granted by the University's Human Ethics Committee.

The pre-semester survey comprised two sections: a reflective section followed by a demographic section. The reflective section was structured horizontally around the concept of deep, strategic and surface learning taken from the Approaches and Study Skills Inventory for Students used by (Anderson, B., 2011); and vertically around the Equivalency of Interaction Theory of student interaction with other students, staff and content (Anderson, T., 2003). This strategy aimed to gather insight in to preferences around interactions by students who indicated tendencies towards deep, strategic and shallow learning; and then to triangulate these finding with demographic data. The survey generated 65 responses. The end-of-semester survey adopted the same vertical and horizontal lines of investigation while reflecting on the preceding 12 weeks. Results of the survey were analyzed using Statistical Package for the Social Sciences (SPSS Inc., Chicago, USA).

Conclusion

Preliminary analysis has highlighted four points: (A) Hearing from students in their own voice was the original raison d'être of this project. Reflective video diaries opened a window in to the lives of twenty participants as they embarked upon their inaugural journeys in to the realm of distance education. From this privileged observation platform, the extent to which stories add flesh to what it means to be a distance learner has become evident. Thus, the value gained from the video diary protocol far outweighed the challenges that arose along the way; (B) Distance education is the mode of choice for 21st century learners who are empowered by the flexibility to assimilate tertiary study around life's less flexible commitments; (C) Digital literacy is hugely variable among distance learners, which presents a challenge as distance education providers transition to online delivery; (D) It is important to make explicit tacit knowledge of what's required to be successful as a distance learner from the outset. Support services for distance learners must be mobilized and advertised at the point of need; and must appreciate the unique challenges that they face in contrast to internal students.

Auditing education courses using the TPACK framework as a preliminary step to enhancing ICTs

Chris Campbell
The University of Queensland

Aspa Baroutsis
The University of Queensland

The *Teaching Teachers for the Future* (TTF) project is a Department of Education, Employment and Workplace Relations (DEEWR) project that involves all 39 Australian teacher education universities. This study uses the TPACK framework and focuses on future teachers to ensure they are afforded the best learning opportunities in an increasingly online world. Specifically, the project supports the ongoing development of information and communication technology (ICT) proficiency of graduate teachers across Australia by building the ICT capacity of teacher educators and through the development of appropriate resources. This paper focuses on the initial auditing and mapping of the electronic course profiles (unit outlines) that occurred at The University of Queensland's School of Education which in turn provided a basis for the specifics of the project. The initial findings of the mapping process indicate that generally, course coordinators under-represent the technology components in their courses.

Keywords: TPACK, pre-service teacher education, Australian curriculum.

Introduction

Teaching Teachers for the Future (TTF) involves all 39 universities that are involved in teacher education in Australia and is a $7.8 million DEEWR funded project which is part of the Australian government's Digital Education Revolution initiative. This project aims to "embed ICT into everyday classroom learning by transforming the delivery of teacher education" (Department of Education Employment and Workplace Relations, 2010). This project takes the notion that teachers who are expert at teaching ICT will assist universities to transform their teaching courses to include more ICT that improves pre-service teachers' technological knowledge and thereby empowering the next generation of school teachers with the necessary skills to make ICT integral to their classroom pedagogy.

While the research indicates that there is a lack of theory and conceptual frameworks that actually guide esearch in the area of teaching with technology (Angeli & Valanides, 2005; Koehler & Mishra, 2008; Mishra & Koehler, 2006; Niess, 2005), the TTF project is underpinned by the *Technological Pedagogical Content Knowledge* (TPACK) framework. This paper specifically addresses the auditing and mapping of university courses which all universities were required to undertake as part of their implementation plan. The mapping task audited the current state of all teacher education courses (units/subjects) in each university with regards to technology implementation. Results from this one university provided more data than expected as well as some unanticipated strengths in current teacher education courses.

Technological pedagogical content knowledge (TPCK, also TPACK) forms the basis of "good teaching with technology" (Mishra & Koehler, 2006, p. 1029). This component identifies the knowledge teachers' use when integrating technology into their subject area. This understanding emerges from the interactions among content, pedagogy, and technology knowledge (Koehler & Mishra, 2009). They stress that good teaching is not simply a matter of "adding technology to the existing teaching and content domain" (Koehler & Mishra, 2005, p. 134). Mishra and Keohler (2006) explain that good teaching with technology requires an understanding of the concepts of technology. As such, Mishra and Keohler (2006) believe that developing technological pedagogical content knowledge should be a critical goal of teacher education. The TTF project focuses on this dimension of TPACK.

Methodology

The electronic course profiles that were analysed were identified as core units for each of the Bachelor of Education (Primary and Secondary) programs, with science and mathematics being specifically targeted. A total of 22 core profiles were reviewed for the Bachelor of Education (Secondary). These comprised of 13 compulsory core units incorporating education theory and professional practice, and curriculum. With regards to the curriculum courses, there are a total of four maths and five science courses. The program also consists of teaching specialisation courses. There were 26 core units identified in the Bachelor of Education (Primary), however, only 17 of these were downloaded and analysed as the Bachelor of Education (Primary) is a new degree and the remaining nine profiles were either not available until semester 2 or not offered until 2012. The course profiles were audited to determine the technological, content and pedagogical knowledge (T, C and P) evident throughout. The following sections of the course profile provided the basis for categorising the course material into the various areas: general course information, aims and objectives, learning resources, teaching and learning activities, and assessment.

Results

The technological knowledge that was evident in lectures, tutorials and assessment in the course profiles has been summarised in Table 1. The knowledge is divided into straightforward uses and complex uses. The straightforward uses were identified as low-level tasks that did not require comprehensive technology skills while the complex uses where identified as those requiring high-level processing skills and technology knowledge. Studies in the United States indicate that while teachers are using technology, it is predominantly used for low-level tasks such as word processing and internet research (Ertmer, 2005) and presentation software and management tools (Harris, Mishra, & Koehler, 2009). Nor should it be assumed that graduate teachers enter the teaching profession with an appropriate level of technology capabilities (Jamieson-Proctor, Finger, & Albion, 2010).

Table 1: Technological knowledge used in teaching (T) and assessment (A)

Straightforward uses	Complex uses	Complex uses continued
Blackboard for information dissemination, delivery of learning modules, submitting assignments (T, A)	Blackboard discussion boards and online quizzes (T, A)	Technology workshops and clinics, Online technology-based activities for students (T, A)
Videos (T)	Concept mapping (T)	Peer teaching (T)

Video taping (T)	IWB flipcharts –developed by students (T, A)	Graphics calculators (T)
Email communication (T)	IWB flipcharts – developed by lecturers (T)	Robotics (T)
Web searches – literature, research material (T, A)	Digital storytelling (T)	Digital literacy (T)
Digital images (T)	Wikis and creating them (T, A)	Online Blog (A)
Online activities (T)	Mobile learning (T)	Wequests (A)
TurnItIn T)	Second Life (T)	Evaluation of digital resources (A)
Internet resources (T)	Web 3.0 (T)	Digital portfolios (A)
Presentations (T)	CMS for website development (T)	Literacy profile (A)
Word processing (T)	Electronic journals (T)	Produce a learning object and develop online games (A)
Multimedia lab sessions (T)	i-Lectures and Podcasts, Slidecasts (T, A)	Form an online learning community (A)
Complete online certification courses (A)	Video Production (A)	
Analyse technology (A)		

When focusing on the complex uses of technological knowledge, the outcomes are advantageous to both the pre-service teachers and the lecturers. While the development of technological knowledge and skills equips the pre-service teachers with the tools that are necessary for the successful integration of ICTs, it also creates a pathway for the integration of technological knowledge and skills within the students' subject area. Further, the students gain practise in developing technologically-rich learning experiences that enhance learning outcomes.

A number of examples identified in this paragraph elaborate on the benefits of integrating complex uses of technology into the teacher education courses. In one course, the students' course evaluation feedback identified over two consecutive years and since the courses inception, received positive feedback and high ratings which "affirmed the value of the highly interactive and experiential lectures and workshops" (The University of Queensland, 2011). This course had a significant technology focus and incorporated many complex uses of *technological pedagogical content knowledge*. In another course, the lecturer runs technology workshops where the students research and design a project that uses complex ICTs and present these to their peers. One of the student presentations in a previous year demonstrated the use of Google Earth software for integration in mathematics classes. The lecturer is now taking steps to become familiar with the software application and incorporate it into that particular mathematics course. Assessment activities also promoted higher order thinking, in both technological and content knowledge, for example the development of online games, and acknowledged real-world experiences, such as preparation of material for a YouTube Channel. While no definitive claims are being made, at the initial mapping stage, it appears as though technology-rich pedagogy enhances the teaching and learning experiences of both staff and students.

A range of technological knowledge is evident in the course profiles, however, following meetings with the course coordinators and lecturers of the audited courses to discuss the mapping, it becomes apparent that the course profiles under-represent the degree of technological knowledge demonstrated in most courses. For example, in one course, which is mandated for study across all three degrees, little or no technological knowledge is acknowledged on the course profile. The course profile identified Blackboard and videos as the only technology used in the course. An informal discussion with the course coordinator revealed that social networking was a central component to the learning that occurred in this course. The School of Education is now investigating this phenomenon further and looking at ways of improving statements of ICT usage in course profiles.

Conclusion

The results indicate that the School of Education courses are both creative and innovative in relation to technology integration. Ferdig (2006) explains that "innovation must contain authentic, interesting and challenging academic content" (p. 750). As the discussion on lectures, tutorials and assessment identified in the course profile will attest to, many of the complex uses of technology (see Table 1) demonstrate the innovative practices in technological knowledge. Further, Ferdig (2006) suggests that teaching and learning practices need to have "authentic, real-world problems, because they are interesting and meaningful to the students and thus engaging" (p. 750). Innovation and creativity was found in the mapping of many of the course profiles and in particular, in the assessment practices of many of the courses. Banas (2010) explains that teachers need to move from a level of "no technology use" to one of "learning from" technology and finally through to a "learning with" technology level (Banas, 2010, p. 126). With many of the complex uses of technology identified in this study, it is hoped that many of the pre-service teachers begin their practice at the "learning with" level (Banas, 2010, p. 126).

The results from the mapping and auditing components of the study suggest that there is a diverse range of technology used across courses in both learning activities and assessment. As a result of the informal conversations with the course coordinators that following the mapping and auditing phase, we became acutely aware that the staff were also using other technologies in ways that have not been identified in the course profiles and consequently not mapped during the audit. This is perhaps a unique situation for an Australian university with further research in this area a future possibility.

This mapping divided technology usage into straightforward and complex uses. After completing the TTF project, this university will have an extensive repertoire of complex technology related teaching and learning experiences for use with primary, middle years and secondary courses. The anticipated changes will be post-tested at the conclusion of the project with another mapping task, where the results will enable a comparison and measurement of the change. Any improvement would benefit graduating pre-service teacher and enable them to commence their careers as individuals who are able to "learn with" (Banas, 2010) technology while also integrating and evaluating technology, for its content and pedagogical appropriateness (Niess, et al., 2009), thereby enabling their *technological pedagogical content knowledge*.

Changing practice: Does the LMS matter?

Helen Carter

James Meek

Vanessa Warren

What are the key drivers to change in teaching practice as they relate to the use of a learning management system? Is one system inherently better than another or is it teacher experience that matters most? Are we expecting academic staff to become 'experts in educational technology' and taking the focus away from developing their discipline expertise? What role do educational designers play in facilitating change in practice? What role does the institution play in supporting change in practice? This paper is meant to provoke discussion around these questions and asks you to consider how this might relate to your own experience and circumstance.

Keywords: LMS, teacher experience, educational design

Introduction

In Australian universities over the last couple of years there has been a noticeable change in the learning management system (LMS) landscape. Increasingly, universities are opting to utilise alternatives to proprietary learning management systems to instead use open source systems. This change is sometimes being coupled with a move to outsourcing the hosting and / or user support of these systems. What are some of the drivers behind these changes and is this making any difference to teaching in higher education?

At first glance this change in the LMS landscape might only seem significant in terms of university management and governance arrangements around how they work with open source systems and in some cases, outsourced hosting of such systems. Certainly these are both issues that need to be considered but does the choice of LMS matter in terms of the approach to teaching? Is there a difference in how teaching staff go about using an open source system and particularly those who have moved from a more constrained proprietary learning system environment?

Open source systems are perceived to be easier to use, not only at the user level but also at the system level; should we be examining the intrinsic affordances that developing a unit of study in an open source system might facilitate, compared to being developed in what might now be seen as a more traditional, proprietary system? This paper seeks to highlight some of the key questions to ask about the role of the software, teacher, educational designer and the organisation – and the relationships between each of these – when examining the impact of the LMS on teaching practice in higher education.

Does the LMS matter?

"…we shape our tools and our tools shape us" (Boettcher, 2007)

The recent change in the learning management system landscape in Australia suggests dissatisfaction with the extant proprietary learning management systems. Bersin (in Aberdour 2008) lists low satisfaction with proprietary learning management systems due to lack of: out of the box functionality; management reporting; ease of customisation; flexible data models and architectures; and vendor service and support. A number of open source systems have emerged as viable alternatives allowing greater customisation and different support models ostensibly facilitated by less up front costs.

Some attributes of an LMS may help or hinder with change in teaching practice, such as basic architecture and 'mood', or emphasis, of supplied functions, and what these suggest. Some of our university teaching staff have just managed to get their head around web design guidelines:having at least the first screen of content (landing page) kept to a single screen of information; of using icons to represent areas of logical organisation, such as lecture content in one spot, assessment items in another, discussion forums in another, and so on; and the importance of white space and uncluttered sites, consistency of naming and layout. There are now many teaching staff who have spent several hours crafting their sites in an effort to achieve these ideals and there is a certain clean logic to dividing a unit of study into these components. Indeed, many proprietary LMS work on the basis of a set of tools that a teacher can use, so consequently sites get developed on this basis. A typical site is established with 5 or 6 icons in the main menu, representing: lecture topics; readings; assessment activities; quizzes; forums and links to resources. Although this might seem the logical way to develop a curriculum for a unit, the focus tends to be on content delivery and one-way communication through seemingly disconnected content and forums. Certainly the design of learning activities have generally not been the prime drivers for the development of such sites.

Other attributes which may help or hinder with change in teaching practice as they relate to the use of a learning management system are its ease of use, predictability, approachability, help materials supplied and any special features. Educational designers would not generally consider themselves to be educational technology experts but they certainly need to understand the possibilities and limitations that might be associated with any particular LMS. Table 1 below provides a potential matrix of factors for consideration in the acceptance of an LMS from the perspectives of teacher, educational designer and the organisation.

Table 1: LMS Acceptance Factors (adapted from Al-Busaidi and Al-Shihi, 2010)

Teacher factors	• Self-assessment of ability to complete tasks using technology • Attitude towards e-learning • Experience / exposure to use of the technology • Teacher Style, from teacher-led to student-led • Personal innovativeness or tendency to experiment with and adopt new technology
Educational Designer considerations	• Purposes for use • Expertise to draw on • Support to learn the mechanics • Support around creative use • Institutional motivation/policy • Institutional guidance/attitude • Time on task for learning, conceptualising and building • Both personal and institutional workload management

Organisational factors	• Organisational support by senior executive • Technology alignment with goals of the organisation • Technical and professional support • Training, using varying formats and approaches • Motivators or incentives provided to support change

The role of the teacher

"When faculty feel that they have greater control over the learning environment, there appears to be increased acceptance of the LMS." (Sclater 2008)

A paper by Oliver and Moore (2008) discusses a number of studies which look at academic use of learning management systems and conclude that as usage of LMSs has continued to increase over time, so too the breadth of tools that are used by academic staff in their teaching has increased. Although initial development of teaching sites will focus on dissemination of information, as confidence grows so too does the use of interaction and communication tools by the teacher. These trends are influenced by the level of study and also the nature of the delivery but does an open source system necessarily afford a different design of learning or is it teacher experience that counts?

The primary paradigm for teaching in Universities has been the delivery of information to students often via the lecture. A lecture may be good for inspiring, motivating and perhaps passing on information through listening but not necessarily good for active engagement. For many years now there has been a move to redefine the role of the teacher as a facilitator of learning and there are more recent moves to put the emphasis once and for all on the learner and learning environment as central by situating the role of the teacher as that of a designer of tasks. These tasks become activities that students undertake in ways that make sense to them. Goodyear (2009) suggests that thinking up good tasks – ones that align with intended learning outcomes – is not easy.

There are a number of ways of encouraging the teacher as the designer which requires acknowledging and supporting the teacher as a professional. This approach is not always easy to pursue, especially with pressures on staff time and energy and resources but this is essential to effectively support change in practice. There also needs to be the backing and understanding of the University executive that teacher development takes time. If units of study are assigned a workload, which is described in terms of lectures and tutorials, then changing practice will be difficult. Enabling staff to change is not just about providing educational design support but also about giving them permission to change. How can we transfer light bulb moments into academic development? (Johnson, 2010) Developing and resourcing appropriate support models to work with staff is important, as attitudes and agreement on what works and what doesn't are many and varied.

The role of the educational designer

"It is now too much to expect academics to be subject experts and experts in education technology. It is too sophisticated. It is unfair, if your field is mathematics then there is another specialist who can take your stuff and put it on the online environment." interview with vice-chancellor Jim Barber in reference to outsourcing of online course delivery to Pearson (Blackwell, 2011).

Many teachers have found ways to bypass or limit their involvement with the 'tools of trade' (as Oliver, 2010 puts it); often investing time and energy into improved learning in the classroom is simply a low priority for busy staff. Even good teachers can assume technology is enough. Technology will not change teaching as we know but designing courses for learning might. Educational designers will ask what blend of pedagogical strategies and technological affordances are most effective for learners?

Educational designers come from a variety of backgrounds and disciplines and there is no formal course of training that can prepare you to be one. In the modern university they have become a staple edition to supporting teaching staff when developing teaching curricula and associated approaches and materials, particularly when coupled with the introduction of a new LMS. They often have to consider quite a broad range of factors, when working with staff, such as: purposes for use; expertise to draw on; support to learn the mechanics; support around creative use; institutional motivation/policy; institutional guidance/attitude; time on task for learning, conceptualising and building; and both personal and institutional workload management.

Does the specific LMS platform matter to a teacher or to an educational designer? How much? What else influences the way they proceed in their work?

The role of the organisation

> "... there is something so seductive about (an) LMS that, despite their complexities and risks, almost every university seems compelled to have one." (Wise and Quealy, 2006)

Expectations of the role and value of learning management systems can be significant from the governing bodies of universities. With the removals of caps on student places in 2012 and greater focus on equity in tertiary education in Australia, the practices of teaching and learning are under continued pressure to change. These pressures to change may or may not reverberate throughout the institution depending how well they are seen to be supported by the senior executive and how well they align with the technological goals of an organisation. Institutionally-run programs that support staff to change their teaching practices and practical incentives to motivate change, demonstrate to staff the value of investing time and effort in changing their practice. How well is this explicated in organisational plans, particularly those relating to learning and teaching and quality improvement frameworks? How well understood is the role of the LMS in supporting change in teaching practice?

Conclusion

The change to any new LMS provides an opportunity to think differently, both from a systems approach, such as using external hosting as a way to creating opportunities, and from a professional development standpoint, by supporting staff to try something different. Anecdotally, staff who have adopted an open source system in their teaching, report changing their approaches but is this just about the tools that an open source system provides that makes the difference? Is it something about a mindset change – a *'just try it'* attitude – but why hadn't teachers done this previously? Some proprietary systems have imputed an attitude of *"here's what you've got – deal with it"* but does this inflate expectations with open source systems that are purportedly able to be extensively / endlessly customised? Does this also mean having to take extra care about how to manage expectations with open source software?

Is it unfair to expect teaching staff to be able to effectively use technology such as a learning management system and should we instead be employing educational technology experts to manage it for them? Should we expend more effort on models of staff development (Zhou & Xu, 2007) that better support our staff needs? Can changing learning management systems really make that much difference to how we teach in universities? There are many issues to consider with the choice of an LMS and considerable time and effort is often expended in making this decision; are we even asking the right questions? There is a need for further research and examination of these questions, particularly in the early stages of LMS transition projects, or applying approaches to existing LMS.

Contextual Course Design with Omnispective Analysis and Reasoning

Srinivas Chemboli
Research School of Computer Science
The Australian National University, Australia

Clive Boughton
Research School of Computer Science
The Australian National University, Australia

In this paper, we present a novel approach to contextualize course design by the application of the Omnispective Analysis and Reasoning (OAR) framework to map the goals and intent of a course to its design and delivery. Effective design and delivery of courses requires alignment between planned learning activities and learning outcomes. However, it is generally not trivial to translate learning outcomes into course design, particularly so when using a Learning Management System (LMS). This is further compounded by the differences between the language of teaching theory and that used by the LMS. Thus, there is a need to effectively capture the rationale for design decisions in a course and map them to desired outcomes. We illustrate the application of the OAR framework with a process for translating a learning objective into course design using the Moodle LMS.

Keywords: Context, Course Design, Moodle, Omnispective Analysis and Reasoning

Introduction

Teaching a course requires planning learning outcomes and goals. These are then mapped to existing educational technologies to deliver the course. However, current learning management technologies often require significant effort to design and organize courses. As a result, teachers are forced to concentrate their efforts on the quirks and methods of the underlying technological platform and this takes their focus away from the goals and outcomes of the course. The activities of online assessment and evaluation tend to become more of a chore, rather than means to support the goals and objectives of a course. This also makes it difficult to share ideas and educational objects across courses and adapt them in a reusable manner.

These difficulties can be overcome by adopting a process that will enable us to:

1. Formalize the implicit rationale in learning outcomes for a course and program of study.
2. Better manage the *intellectual effort* (underlying concepts, ideas and theories) in the design and implementation of a course.
3. Explicitly capture and manage the learning *context* associated with the effort.

To this end, we utilize Omnispective Analysis and Reasoning (Chemboli, 2010a) to develop a reusable specification (recipe) in order to enable flexible organization and management of courses using a learning management system such as Moodle. First, learning objectives and outcomes of a course are captured using an enhanced model of curriculum design. These concept level concerns are then expressed as *model level* concerns in terms of existing educational models in the form of a specification, which conforms to and is in terms of the concept level concerns. Finally, the design decisions of a course are implemented using a learning management system and associated educational technologies, enabling a two way mapping between the educational goals and resources in the underlying technological platform. This will not only enable teachers to map their course outcomes to the underlying educational technology, but will also facilitate evaluation of the effectiveness and suitability of various teaching goals and outcomes.

The remainder of this paper is organized as follows. In the following section we discuss the issues encountered in translating learning outcomes to course design, especially when using a Learning Management System (LMS) for course delivery. Next, we present an overview of the Omnispective Analysis and Reasoning framework, highlighting its main features and approach to concern and context refinement. This is followed by a discussion of the OAR process for contextualizing course design. We illustrate the application of the OAR framework with a process for translating learning outcomes into course design using the Moodle LMS, with particular focus on one learning objective to provide further detail. In the end, we give summary and conclusions and indicate direction of future work.

The Problem of Translating Learning Outcomes to Course Design

The application of Biggs' theory of constructive alignment (Biggs, 2003) to design course content results in an effective approach to course delivery. Constructive alignment requires that the teacher align the *planned learning activities* with the *learning outcomes* (Houghton, 2004). However, one often encounters mismatch and difficulty in mapping the *language of the learning outcomes* to the *resources* and *processes* of the Learning Management System (LMS). This mismatch is mainly because of the different natures of the domains of course design and learning outcomes and the LMS. For instance, while learning objectives for a course may be formulated in terms of the desired goals and means for assessment and evaluation of effective learning, the implementation of the course in an LMS is undertaken in terms of LMS resources such as lessons and exercise blocks, and widgets like buttons and checkboxes, accompanied by participatory student activities such as discussion forums, quizzes and chats. Therefore there is a need to provide a link between the pedagogical concepts and their implementation in an LMS such as Moodle (Rice, IV, 2007). Online instruments will further help this linking of Moodle activities and resources to learning outcomes.

Developing Outcomes for a Course

Courses are driven by outcomes and objectives. Developing an effective course requires answering the following questions:

- What are the learning outcomes for the course?
- What is rationale of the learning outcomes?
- What objective measures can be formed to assess student learning?

These learning outcomes are usually expressed as a *course description statement*.

Difficulty and Disconnect in Mapping Outcomes of Activities / Resources in a Learning Management System

We encounter the following difficulties while translating the intent and learning outcomes of a course into activities and resources in an LMS implementation:

- Resolving the differences between language structure and terminology used in defining learning outcomes

and the Moodle implementation.
- There is an apparent disconnect between stating goals of a course and developing a course in Moodle.
- Lack of an effective means to capture the *rationale* for design decisions in a Moodle implementation (which activity / resource is chosen and why, what are the tradeoffs in using different resources to achieve the same outcome).
- Communication and collaboration issues that emerge in the interaction between course designers, lecturers and LMS developers.

Learning Outcome Rationale

The preliminary process of understanding the rationale for learning outcomes begins with identifying relevant *concerns* of interest in the course under consideration. We apply the Omnispective Analysis and Reasoning (OAR) framework to analyze the desired learning outcomes against accepted exemplars (*external prototypes*) presented by Ramsden (1992) and Biggs (2003) as applicable to the context of research-based education (*constraint factor*) at the ANU (Strazdins, 2007). We elaborate the process of linking this analysis in the example discussed later in this paper. This results in capturing the basis for course design in a repeatable manner which can be mapped to the outcomes of the course.

The Omnispective Analysis and Reasoning (OAR) Framework

The OAR framework has been developed to address the problem of capturing and reusing the intellectual effort in scientific workflows (Chemboli, 2010a). In this framework, a scientific workflow is defined as any logical and repeatable inquiry, investigation and set of actions.

The main features of OAR are:

1. Omnispective: The framework provides an outward looking rich context perspective for analyzing and reasoning about the underlying concerns in a problem situation.
2. Epistemic: Provides explicit support for evidential validation in a repeatable manner.
3. Managing intellectual effort: Capturing and reusing theories, concepts, interactions and constraints in recipes and prototypes. Exploratory domain concepts, scientific models, representation of theories and process specifications are represented in recipes (prototypes, archetypes and constraints).

Managing Concerns in OAR

In OAR, all the concerns that are identified in the problem domain are collected and managed at three levels – the concept, model and execution levels. Figure 1 illustrates the idea of hierarchical concern management in the OAR framework.

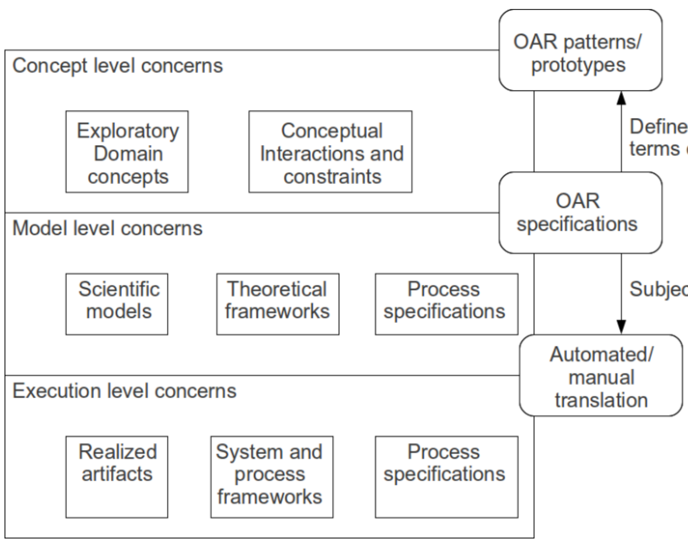

Figure 1: Hierarchical concern management in Omnispective Analysis and Reasoning

All individual concerns that emerge from an analysis of the domain of the present investigation (Scientific Activity) are extracted as recipes. At the *concept level*, these include exploratory domain concepts and the interactions and constraints between them. These aspects of the domain are represented in recipes (OAR patterns and prototypes). Each OAR prototype encapsulates the identified knowledge for a concern in the domain to varying degrees of firmness. At the *model level*, we describe physical and logical systems in terms of formalisms incorporating physical theories and paradigms. These are abstracted in mathematical and analytical models, vocabularies, data sets, natural language representations, ontologies and process guidelines. These abstractions (OAR specifications) are *defined explicitly in terms of and conforming to* the OAR patterns and recipes which have been identified at the model level. Since the OAR specifications are always defined exclusively in terms of OAR patterns, they will be easy to verify and validate for conformance and well-formedness. Finally, at the *execution level* the OAR specifications are implemented by automated/manual translation utilizing different available process specifications, system and process frameworks and known implementation platforms while *satisfying the requirements* of the OAR patterns/recipes which constitute the specification detail. Thus, the hierarchical nature of the OAR framework will ensure an end-to-end coordination between individual concept level concerns, their model representations and the corresponding implementation and execution in terms of available platforms, technologies and frameworks.

Concern Refinement

Depending on the degree of *firmness* and relevance, we categorize OAR recipes in three types – *prototypes, archetypes* and *constraints*. A *prototype* is any OAR recipe that is available in a given domain without particular consideration of its applicability, degree of formalism or robustness for any fitness or purpose. Thus, a prototype can encapsulate either nascent or well-formed domain concerns that may be available to support the analysis of any problem situation with the OAR framework. An *archetype* is a prototype that can be considered an *exemplar* or a *best practice* recipe for a concern in a particular domain. The choice of an archetype is dependent upon the analysis of the problem under consideration and influences our net understanding of the problem domain. A *constraint* is a special instance of an archetype which is identified to impose strict criteria on an OAR specification. A *valid* problem solution is required to *sufficiently satisfy* all requirements of the constraint without exception, and is often subject to rigid conformance.

Individual concerns (recipes and patterns) in OAR are managed in collections known as a *shelf*. A shelf is simply an unordered collection of recipes categorized by domains and their relevance to any problem under consideration using the OAR framework. As illustrated in Figure 2, OAR recipes (prototypes, archetypes and concerns) are organized in three categories of shelves – *external*, *problem domain* and *solution*.

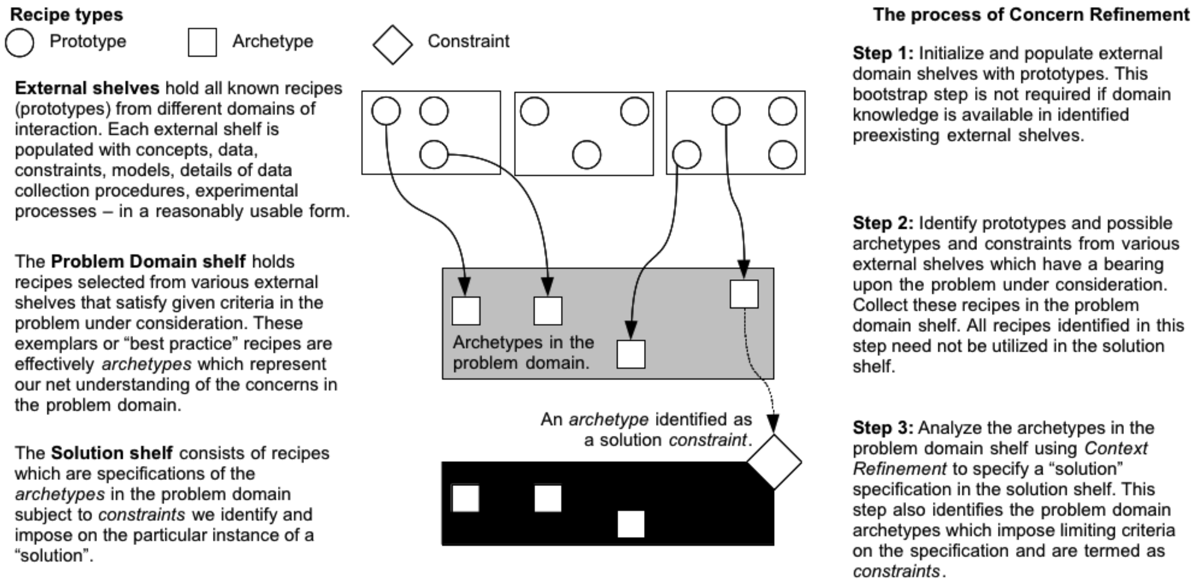

Figure 2: Managing concerns with recipes and shelves in the OAR framework

Context Refinement

The determination of which recipes are relevant to a problem domain is carried through the process of context refinement. Context specifies the degree of relevance of individual recipes in the problem domain. We manage context in the OAR framework by utilizing an enhanced model of context which extends the foundations proposed by Alshaikh and Boughton (2009). In the OAR framework, we consider context as a function of two dimensions: *firmness* and *influence*.

Firmness is a measure of the degree of wellformedness of the recipe (prototype) under consideration in a shelf. If the prototype is ambiguously defined, vague, or peppered with implicit characteristics, the knowledge encapsulated in the prototype can be considered to be quite *pliable*. On the other hand, an explicitly defined and well-formed prototype can be considered to be *firm*.

Influence is a measure of the effect exerted by the prototype in the analysis of the problem domain. If a prototype in an external shelf is identified as relevant to the problem domain, then the prototype exerts a non-trivial influence on the analysis. If it exerts a *strong* influence on the analysis, then the prototype is identified to encapsulate "exemplar criteria" or "best practice" for the problem situation, and can be considered as an *archetype* in the problem domain. If the prototype does not affect the problem domain, but may still be considered relevant, it is identified as exerting *weak* influence.

Considering these two dimensions, OAR recipe context (C) is defined as a function of *influence* (I) and *firmness* (F) (illustrated in Figure 3) as C = f(I, F).

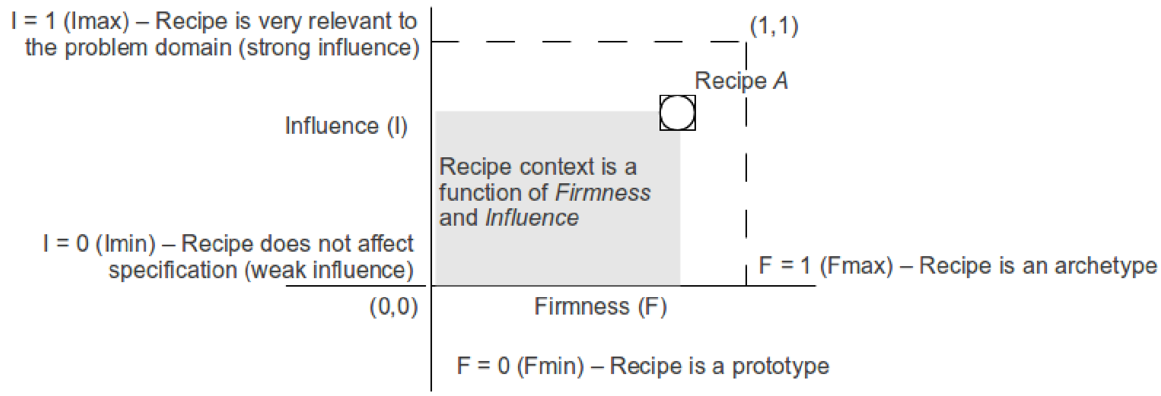

Figure 3: OAR context recipe as a function of Firmness and Influence

At the outset, all recipes are assumed non-contextual and not relevant to the problem under study. If analysis suggests the use of a particular recipe, then it becomes contextually relevant for the problem. In addition, if the recipe falls under the category of an "exemplar" or "best practice" in the discipline, then it becomes both relevant and contextually explicit for the problem under consideration. Consequently, the specification composed from the selected recipes will become increasingly *firm* as situational and imposed constraints are satisfied. Though OAR recipe context is a continuous function of two dimensions, in most circumstances, recipe context can be conveniently tagged by discrete labels of the function f(I, F) affecting prototype selection:

1. C(I=0,F=0): a context state corresponding to weak influence and low firmness.
2. C(I=0,F=1): a context state corresponding to weak influence and high firmness.
3. C(I=1,F=0): a context state corresponding to strong influence and low firmness.
4. C(I=1,F=1): a context state corresponding to strong influence and high firmness.

The process of context refinement (Figure 4) is used to determine the relevance and influence of the recipes to a problem domain.

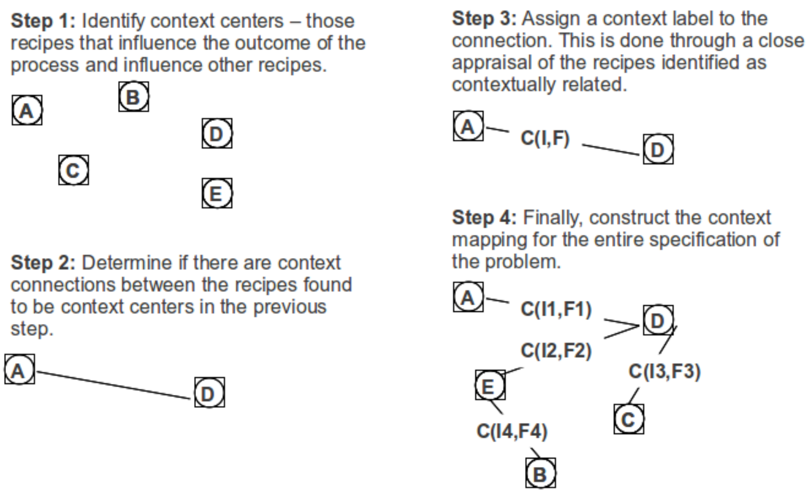

Figure 4: Context refinement in the OAR framework

The first two steps of context refinement in Figure 4 may be carried out recursively to obtain a complete mapping of the context relationship in the final specification.

The OAR Process for Contextualizing Course Design

In this section, we demonstrate the application of Omnispective Analysis and Reasoning for developing a contextual specification of course design. First, learning objectives and outcomes of a course are captured using an enhanced model of curriculum design. These *concept level* concerns are then expressed as *model level* concerns in terms of existing educational models in the form of a specification. Finally, the design decisions of a course are implemented using a learning management system and associated educational technologies, enabling a two way mapping between the educational goals and resources in the underlying technological platform.

After identifying the learning outcomes for the course, we execute the following steps:

1. Choose an outcome for the course.
2. Identify the characteristics of the outcome.
3. Using an online instrument (Chemboli, Kane, & Johns-Boast, 2010) to identify the Moodle resource/activity or associated technology which supports the development of these characteristics.
4. Develop the Moodle activity/resource to satisfy the outcome.

Translating Learning Outcomes for COMP8120

COMP8120 was a mandatory course in the Master of Software Engineering Program at The Australian National University. The Master of Software Engineering was aimed at updating and equipping software and systems engineering professionals with a repertoire of best practices and paradigms, empowering them to make informed decisions and evaluate their impact in a measured and systematic manner.

Learning Objectives for COMP8120

1. **[LO-1]** The students will develop an appreciation of past, contemporary and emerging software/systems analysis and design techniques.
2. **[LO-2]** The students will be able to evaluate and understand the scope, applicability, limitations and extensibility of software/systems analysis and design techniques.
3. **[LO-3]** They will be able to apply and expand the methodologies to accommodate appropriate multidisciplinary knowledge, and inform decisions affecting problem situations.
4. **[LO-4]** Students will use the approaches learnt to identify necessary improvements and inform recommendations about their realization using appropriate and well-informed inputs from multiple sources of knowledge and expertise.
5. **[LO-5]** The students will reflect, inform and communicate the issues in the integration approach identified

for improving a problem situation to the satisfaction of all stakeholders identified.

Analyzing Context for [LO-1] and [LO-2]

It is assumed by the designers of the course that students may not be conversant with system/software development methodologies (*ssdm*), or their application to specific problem situations (*ps*). We express this in the following context statement:

student C(I=0,F=0) *ssdm* C(I=0,F=0) *ps*

Students are introduced to subject matter pertaining to the detail and process of various methodologies, *without concern* for specific usage scenarios. Following this activity, students will now possess the requisite knowledge of system/software development methodologies even if they may still not be aware of areas of application of specific methodologies. Thus, students will acquire *explicit* knowledge of methodologies, although they may still be unable to contextually apply them to targeted problem situations. This can be expressed as:

student C(I=0,F=1) *ssdm*

Analyzing Context for [LO-3]

The students participate in guided learning exercises concerning the development of understanding and evaluation of problem situations while developing informed recommendations *without particular emphasis on solution strategies*. This phase of learning is governed by efforts to *credit local knowledge*.

student C(I=1,F=0) *ps* C(I=0,F=1) *ssdm*

Analyzing Context for [LO-4]

The students now undertake activities to iterate through *constraints* that bear upon a particular problem situation and formulate and develop *implementation processes* in accordance with all identified aspects of the problem domain. An early design decision by the course organizers required that the students employ the Aspect-Oriented Thinking (AOT) framework (Flint, 2006) for this purpose. Consequently, the choice of the AOT framework is a firm constraint (no alternatives are considered).

student C(I=1,F=1) *ssdm* C(I=1,F=1) *ps* C(I=1,F=1) *AOT*

Analyzing Context for [LO-5]

The students are to undertake activities to effectively *communicate* and *collaborate* in order to actively arrive at an agreement on the identified intervention in a problem situation.

student C(I=0,F=1) *communication and collaboration*

Solution Specification for [LO-5]

As a further illustration, we now discuss the OAR process for formulating a solution specification for implementing communication and collaboration for [LO-5] using the Moodle LMS (Chemboli, 2010b). Although the process for defining solution specifications for the other learning objectives is not presented here, they are defined in a similar manner.

Initialize External Shelves

We identify the following external shelves (Figure 5) with prototypes for designing the specification for realizing [LO-5].

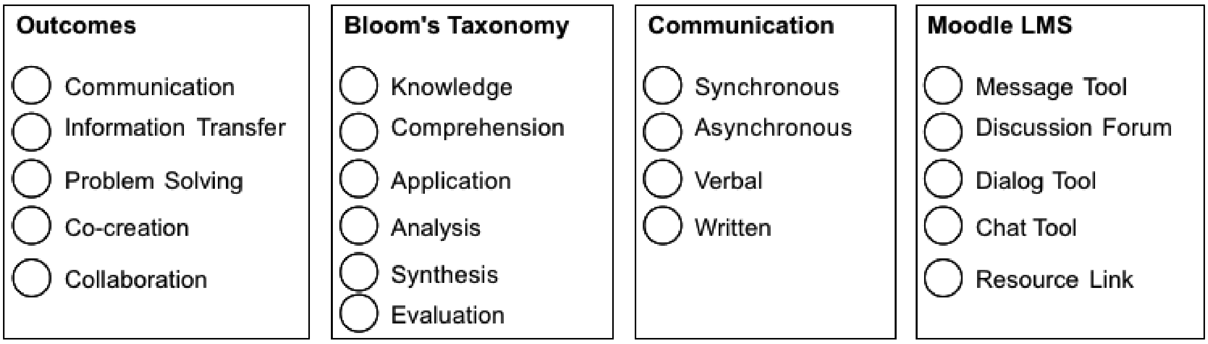

Figure 5: External shelves and prototypes

We utilize Bloom's taxonomy in order to align the learning outcomes of COMP8120 with assessment criteria. Hence, we identify the prototypes for assessment modes in Bloom's taxonomy as relevant recipes for consideration. The Outcomes external shelf presents us recipes for the activities pertinent to [LO-5]. Written or verbal communication between students can either be synchronous (in real-time) or asynchronous. These recipes are collected in the Communication external shelf. Since, we intend to implement [LO-5] using the Moodle LMS, an external shelf with resources and activities supporting communication and collaboration in Moodle is considered.

At the time of designing this course, we used Bloom's taxonomy (Bloom, 1963). There is nothing inherent in the OAR framework which mandates the kind of taxonomy used. The revised Bloom's taxonomy (Churches, 2008) can be incorporated in a straightforward manner as another external shelf which provides additional prototypes for consideration in the solution specification.

Identify Relevant Archetypes and Constraints

Next, we perform concern refinement for [LO-5] in order to select the specific prototypes which can be imported into the problem domain shelf. [LO-5] states the requirement for *active* communication and collaboration. The recipes for Communication and Collaboration are selected from the Outcomes external shelf. We also identify two constraint recipes – *Synchronous* and *Written* from the Communication external shelf. The students are required to communicate and collaborate in a synchronous fashion using written tools (these constraints are imposed by the course designers). Utilizing Bloom's taxonomy, we can align [LO-5] with assessment of Application skill. The students are required to utilize the communication platform to execute stakeholder engagement. Finally, we also select the prototypes for the activities in Moodle which support communication in a written form. The resultant problem domain shelf is illustrated in Figure 6.

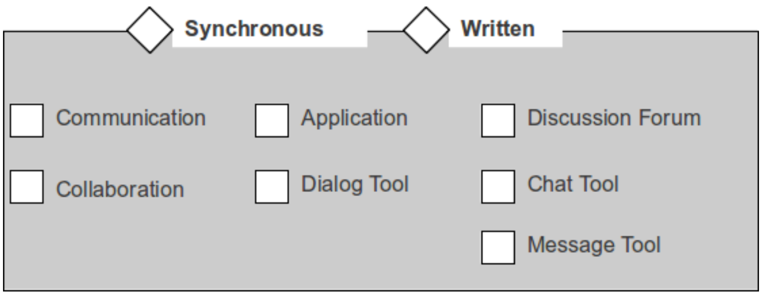

Figure 6: Archetype and constraint identification for [LO-5]

Solution Specification for [LO-5]

We now undertake the process of Context Refinement to define the solution specification for [LO-5] (Figure 7). The process is outlined in the following specification statements.

[SS-1] The *Communication* archetype needs to be implemented in a *Synchronous* and *Written* fashion. *Synchronous* C(I=1F,=1) *Communication* C(I=1,F=1) *Written*.

[SS-2] Although the Dialog Tool, Discussion Forum and Message Tool can be used for synchronous communication, they are not particularly suited for interactive text exchange between participants. Therefore, only the Chat Tool satisfies the requirement of synchronous communication, and is imported in the solution shelf.
Synchronous C(I=1,F=0) *Chat Tool*.

[SS-3] The Chat Tool was selected because it is a writing tool.
Written C(I=0,F=1) *Chat Tool*.

[SS-4] The use of the Chat Tool will satisfy the requirement for assessing how the students apply the skills learnt via [LO-5] because the course coordinators can assess the chat logs for significant contributions. Thus, we can state this as:
Chat Tool C(I=0,F=1) *Application*.

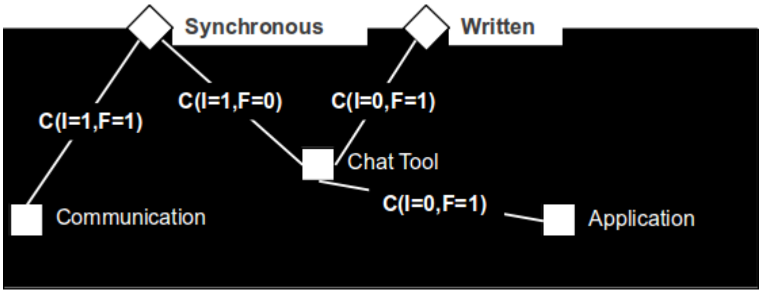

Figure 7: Solution specification for [LO-5]

Implement Solution Specification

Finally, we implement the solution specification for setting up a chat tool for satisfying [LO-5]. This is achieved through either manual or automated translation using the information provided by the archetype for the chat tool. In this case, we utilize a Moodle workflow for setting up the chat activity in the LMS (Chemboli, 2010c), which is specified in the chat tool recipe that was imported from the Moodle external shelf during the process of concern refinement. The use of the chat tool satisfies the design requirement for [LO-5] (synchronous and written communication) which is specified in Figure 7.

Summary and Conclusions

In this paper, we have presented the application of the Omnispective Analysis and Reasoning (OAR) framework to contextualize course design by mapping the goals and intent of a course to its development and delivery. This is a novel approach and we expect this will support the development of courses which robustly satisfy their learning outcomes. We align the learning outcomes of a course with activities related to teaching and assessment by explicitly capturing the context of course design using an enhanced context paradigm. We have illustrated this process by the example of a specification to satisfy a learning outcome for synchronous and written collaboration between students in a software engineering course using the Moodle LMS. We expect that adding support for capturing and incorporating context and rationale using the OAR framework will greatly aid the process of course design. Though we have not explicitly addressed the idiosyncrasies of learners and instructors in the example presented, these can be incorporated by adding prototypes from relevant external shelves. As a further extension to the work presented in this paper, we are currently developing a "Context Plugin for Moodle". This is an OAR workflow plugin to capture and represent the intellectual effort in course design and manage its context within the Moodle LMS itself.

This paper discusses the significance of a research project between Charles Sturt University (CSU) and Massey University (MU) which aims to build knowledge and understanding of the impact of distributive leadership approaches to transforming teaching and learning in relation to distance education. Authentic, situated approaches to change offer a powerful conduit for building “street level leadership”, the sharing of knowledge, skills and information within and between schools and as a basis for whole-of-institution cultural change driven through practice. This research provides an opportunity for evaluation of authentic, situated approaches as a mechanism for institutional renewal of learning and teaching practices in relation to distance education (DE). Such a

reorientation of practice affords CSU and MU a chance to increase the equity of student experience and engagement in learning through blended and flexible delivery.

Keywords: Distributive Leadership, Institutional Change, Distance Education, Blended and Flexible Learning, Case study research

The changing environment

The Higher Education Sector faces many challenges in the 21st Century, especially in respect to the quality of learning and teaching in the digital age. Academics remain focused on the development of new knowledge and discipline expertise, yet students increasingly demand high quality learning and teaching expertise. Consequently, changes in learning and teaching practices need to be achieved to counteract this divergence. Gourley (2010) argued these "new dynamics in higher education require a fundamental shift in the way in which institutions conduct their affairs, from leadership and strategic thinking to management and fundamental operations" (p. 34). Professional Development (PD) is recognised as one means of facilitating this transformation (see for example, Stes, Clement & van Petegen, 2007; Spillane, Halverson & Diamond, 2004), however, "effective staff development of academics remains a challenge" (Kerr, 2010 under blind review). This raises the question of what an institution can do to foster innovative learning and teaching approaches?

Addressing these changes

The University Sector has adopted a wide range of strategies in an attempt to foster change in learning and teaching in response to these new times. Charles Sturt University (Australia) and Massey University (New Zealand) wanted to collaboratively understand and learn from insights about their respective strategies, and to this end in 2010 was successful in gaining funds from DeHub to support two research projects. Through change, both institutions seek to transform the student experience, leading to quality and equitable outcomes for students. Both institutions have a history of DE that reflects the generational models developed by Taylor (1995) – the Correspondence Model, Multimedia Model, Telelearning Model, and the Flexible Learning Model based on online delivery via the Internet. In reality, all four models co-exist, in various ways, at the partner's institutions. The speed of change has posed significant challenges in generating "qualitatively different teaching-learning environments, pedagogical practices and organisational infrastructures" necessary to shift from first to fourth generation DE (Taylor, 1995). To complicate matters, both institutions have entered a "fifth generational" phase, where a focus on innovative and transformative learning design based on blended and flexible learning has evolved. In response to these challenges, both universities have sought institutional renewal through shifting cultural practices associated with conventional distance education towards blended and flexible learning. Knights, Myer and Samson (2007, p. 237) proposed that "rich workplace learning" (in their case, team-teaching) offered greater opportunities to achieve sustainable change in learning and teaching practices than "formal programmes of professional development for academics, particularly in the early stages of their teaching careers". The premise of the PD approaches taken at CSU and MU is that one way of achieving this "fundamental shift" is by adopting strategies that aim to build learning leadership capacity and local agency.

In their review of the literature, Southwell and Morgan (2009) reported to the Australian Learning and Teaching Council (ALTC) that "academic development initiatives are seldom studied systematically" and that the ALTC needed to "fund projects that specifically focus on quality teaching for learning through the development of leaders" (pp. 3-4). We know that PD can transform learning and teaching and impact on the quality of student learning opportunities (see for example, Stes et al., 2007; Spillane et al., 2004), however "effective staff development of academics remains a challenge" (Kerr, 2010 under blind review). Tynan et al. (2010) argued that "successfully embedding change of instructor practices for enhancing student learning in distance education modes" requires a number of support mechanisms including "institutional readings", "an institutional response to professional development" and the development of "impact evaluation indicators". Thus, these findings illustrate the need for systematic research, such as that proposed by the research project, to evaluate the strategies and impacts of initiatives that support academic development.

Substantial effort has been expended at the partner's institutions in pursuing cultural change in learning and teaching practices in relation to DE, open and distance education. Both institutions have adopted authentic, situated approaches that provide mechanisms of support for individual academics, and teams, to develop genuine solutions to learning and teaching challenges. Scott, Coates and Anderson (2008, p. 99) proposed that developing "learning leaders" was an essential component in institutional change, which aligns with the body of knowledge (for example, Sergiovanni, 2000; Knight & Trowler, 2001; Spillane et al., 2004; MacBeath, 2005) that proposes "distributive leadership" approaches to change provide institutions with an opportunity to foster leaders *in situ*. Jitse, Nelson, Billsberry and van Muers (2009, p. 767) argue that "one of the defining principles of distributed leadership is that it arises from the interactions of diverse individuals in a setting where expertise is a dispersed quality" (See also Keppell, 2009; Spillane et al., 2004; Gronn, 2002). Distributive leadership is not about "delegated headship", rather it is about situated leadership regardless of rank or role, where decision-makers understand their locus of control, the forces that drive and constrain it, and innovate or transform the learning and teaching spaces within, and where possible, connected to, their "situatedness".

Distributive leadership and cultural change at Charles Sturt and Massey Universities

Charles Sturt and Massey Universities had separately and independently adopted institutional and professional development strategies designed to engage academics in change at "the sharp end" of practice. The general approach taken by both Universities was a capacity building one that "on the ground" appeared to bear some of the characteristics of DL. The characteristics of "distributive leadership" were identified. Distributive leadership in this research was defined as "the distribution of power through a collegial sharing of knowledge, of practice, and reflection within the socio-cultural context of the university...through a "faculty scholar model" (Lefoe et al., 2008, pp. 1-2). Distributive leadership is characterised by the building of trust, creation of a learning culture and the sharing and dissemination of information (Brown & Littrich, 2008) an is supported through a number of domains, such as growing, reflecting, enabling, engaging and networking (Lefoe et al 2008, p. 3) and "gives quality time" (Schneider, Applebee & Perry, 2008, p. 898) to institutions to enable them "to investigate, learn, experiment and develop better solutions if they wish to become effective learning organisations" (Fullan, 2006, p. 121). It assumes situated leaders are able to generate change, not only in relationship to their immediate locus of control, but also through impacts generated through professional networks, collegiality and communities of practice.

Methodology

A qualitative research methodology was adopted, using a case study approach. Through descriptive case studies, "stories of adaptation" in blended and flexible learning, open and distance education will be developed in three domains of activities - institutional, course-based and individual. This research conceptualised institutional change as a consequence of strategies and interventions used to encourage resilience, innovation and adaptation. The idea of institutional change was largely tied to changes in learning and teaching practices, such as practice experimentation, changes to pedagogy and changes achieved through course design, rather than to institutional change such as Senate policy or workload agreements. The cases therefore included insights into practice experimentation as the source of locally mediated leadership and institutional change connected to widening circles of influence. Eight cases were identified (six at CSU, and 2 at Massey) of strategies that had been introduced by the respective institutions to foster change in learning and teaching. Three of these cases (at CSU) were explicitly developed using a distributive leadership approach; the remaining five (CSU and Massey) were developed to build learning and teaching leadership. Development of the case studies was informed by the literature concerning successful leadership and capacity building through distributive leadership. In summary, these characteristics included (Lefoe et al 2008, p. 1-4):

1. Formal leadership training & professional development activities
2. Authentic learning activities that are situated in real contexts
3. Engagement in reflective practice
4. Opportunities for dialogue about leadership practice and experiences
5. Activities that expand current professional networks
6. Leadership encouraged regardless of formal position
7. Strong institutional support
8. Leadership negotiated rather than delegated

The case studies as stories of adaptation

Of the eight case studies, only three were explicit examples of distributive leadership. Five were examples of capacity building in learning and teaching that aimed to develop learning leadership; and were characterised by at least five of the eight characteristics identified by Lefoe at al (ibid). The case studies are as follows:

Organisational Domain	**Case Study**
Institutional	• Annual, internal Learning and Teaching conferences (CSUEDs) • The introduction of Stream (MU) • The introduction of ePortfolios at CSU • The Teaching Fellowship Scheme (CSU)
Course-based	• The introduction of Course team Symposiums (CSU) • The redesign of Sociology in the Faculty of Business (MU)
Individual	• In-depth case study: Teaching Fellow 1 • In-depth case study: Teaching Fellow 1

The case studies are being developed with the following common focus areas:

1. Overview
2. Background
3. Visions and Aims
4. Strategies and Activities
5. Outcomes
6. Reflective practice and practice experimentation
7. Connections, collegiality and networks
8. Reflections on leadership development

The “background” of each case study will be informed by the driving and constraining forces (Lewin, 1951) operating at the respective institution For example, in the CSU context numerous institutional elements will act as drivers of course-based planning – Senate requirements, Course Directors, Common Teaching Standards, B&F Learning principles, Learning Management Systems and approaches to PD at CSU and MU. Two of the cases (of Teaching Fellows within the Flexible Learning Institute) include journey and conjecture mapping (Sandoval, 2004, Westbrook, Coiera, Gosling & Braithwaite, 2006) to provide a structure to understanding the different levels of granularity in the educational designs that emerged during the study.

Current activities

By December 2011, a literature review will be completed, and the conceptual framework and methodological approach will have been refined. Six case studies will have been largely developed, with two to be developed in early 2012. A project web site has been developed, and the findings of the study will be published as a wiki.

Lessons Learnt

The original research plan referred to "design based research" and proposed that the cases studies would be examples of "distributive leadership". Field work has lead to revision of both. Firstly, six of the case studies are largely being developed retrospectively, drawing on secondary data. As such they take the form of descriptive, historic cases that do not involved participants in the development of participatory research. Two of the cases studies (in-depth, of the Teaching Fellows at CSU) are partially auto-biographical, involving reflection about their learning and teaching decision-making. As such, the research is being conducted as case studies, and do not involve design-based research.

Secondly, while three of the cases are of strategies that were explicitly developed as distributive leadership (related to the Flexible learning Institute Teaching Fellowship Scheme, CSU) five were not. Therefore, rather than conceptualizing the case studies as examples of distributive leadership, the cases will be interrogated from the perspective of the *characteristics* of DL as these find meaning in the aspirations of both institutions in terms of the development of learning leaders. Through this lens, the research will identify its current strengths, and establish a framework for future systematic improvements, informed by distributive leadership approaches.

Singapore student teachers' intentions and practices in integrating technology in their teaching

Doris Choy, Angela F. L. Wong & Seng Chee Tan
Learning Sciences and Technologies Academic Group
National Institute of Education
Nanyang Technological University, Singapore

The purpose of this study is to investigate the development of student teachers' intentions and practices in integrating Information and Communication Technology (ICT) into teaching. Data was collected before and after the ICT course on their intentions to use ICT in future teaching, and after the two practicum school attachments to find out their practices in integrating ICT during their student teaching. The results showed that student teachers' intentions to integrate ICT were positive before and after the ICT course. There was a significant decrease in their practices to integrate ICT as an administrative tool and a student learning tool during the first practicum attachment. However, there were significant increases in their ICT practices during their second practicum attachment. The student teachers also reported positive overall attitude towards the use of ICT in teaching throughout their two-year teacher education programme.

Keywords: technology integration, intentions, practices, practicum attachments

Introduction

Integrating information and communication technology (ICT) into the classrooms has been a major initiative worldwide. Many research studies in ICT integration focused on student teachers' attitudes, beliefs and perceptions (Phelps & Maddison, 2008; Swain, 2006). However, limited studies have investigated the student teachers' intentions to use ICT in their future teaching and their practices in using ICT during their teaching.

Ajzen and Fishbein (1980) defined intention as an anticipated outcome that guides a person's planned actions or behaviour. It could be a measurement of the likelihood that a person will engage in a given behaviour in the future. Therefore, in this study, the student teachers' intention is defined as their likelihood to integrate ICT in their future teaching. On the other hand, the student teachers' practice is defined as their behaviours in integrating technology during their five-week Teaching Assistantship and ten-week Teaching Practice attachments. Recent studies reported that student teachers have positive intentions to integrate ICT in future teaching (Choy, Wong, & Gao, 2009). The new generations of student teachers seemed to have higher confidence and self-efficacy in integrating technology in their teaching (Wang, Ertmer, & Newby, 2004). However, most of their ideas about technology integration remained superficial because they perceived that using ICT tools to present and capture their students' attention were considered using ICT effectively (Choy et al., 2009).

Constructivist learning theory was adopted as the theoretical framework of this study. Student teachers construct their own meaning about integrating ICT in teaching through the interactions of what they already know with the new ideas and activities which they experience (Brophy, 1991). This study investigated the student teachers' intentions to integrate ICT after they completed a course related to ICT pedagogy and their practices in ICT integration during their practicum attachments.

Background

The student teachers in this study were enrolled in the Diploma in Education programme. This programme was designed for those who have graduated from high schools or Polytechnics. During their two-year study, all student teachers are required to complete an ICT pedagogy course. There are two practicum attachments in this programme. After completing their first year of course works, the student teachers are sent to different schools for their five-week Teaching Assistantship (TA) attachment. During the TA attachment, the student teachers observe their cooperating teachers (CTs) for two weeks and begin to co-teach with their CTs in the last three weeks. At the end of their teacher education programme, they have to complete a ten-week Teaching Practice (TP) attachment where they have to plan and teach lessons independently.

Methodology

The purpose of this study is to investigate the development of student teachers' intentions and practices in integrating Information and Communication Technology (ICT) into student teaching during their teacher education programme. There are four data collection points in this study. The student teachers' intentions were measured before and after they completed the required ICT pedagogy course. Their practices during practicum attachments were measured at the end of their two practicum attachments, namely the five-week Teaching Assistantship (TA) and the ten-week final Teaching Practice (TP).

The research questions are:

1. What are the student teachers' intentions to integrate ICT in their future teaching?
2. What are the student teachers' practices to integrate ICT in their practicum attachments?
3. What are the changes in their intentions and practices?
4. What is their overall attitude towards ICT integration in teaching?

The participants of this study were student teachers who were enrolled in the two-year Diploma in Education programme at the National Institute of Education, Singapore. Ninety-one out of 327 participants were included in the data analysis, indicating a return rate of 27.8%. Missing data was replaced with means score and surveys with substantial missing data were omitted for analyses. The average age was 24.5 years (Std. Dev. = 4.9) and 56% were female participants. Although the response rate is low, we believed that it is acceptable as it took two years to complete the data collection.

The survey instrument used in this study was adopted from a previous study (Choy et al., 2009). As the objective of this study was to investigate the intentions and practices of the student teachers during their school attachments, only 22 out of the 38 items were adapted from the existing instrument. The survey used a 4-point

Likert scale, which ranged from 4 = "*all the time*" to 1 = "*never*" to measure intentions and practices. In addition, seven items were added to the survey to assess student teachers' overall attitude towards integration of ICT in teaching. The items in the survey were the same throughout the four data collection points. However, slight changes were made to the wording of the items to measure the intentions and the practices of the student teachers at different data points.

Data Analysis and Results

Exploratory factor analysis was conducted to analyse the data collected. Using SPSS 18.0, factor analysis with Varimax rotation showed three factors that carried eigenvalues higher than 1.5. The factors were labelled as: ICT as administrative tool; ICT as teaching support tool; and ICT as student learning tool. Each factor had five to seven items. The reliability for the whole survey was high (0.98) and the reliability coefficient for all three factors ranged from 0.77 to 0.90, which showed that the instrument was reliable.

In order to compare the means of the student teachers' intentions and practices from before their ICT course to the end of their TP attachment, multiple analyses of variance (MANOVA) for repeated measures were used to analyse the data. MANOVA results showed that there were significant differences in all three factors when comparing the means across the four data collection points (see Table 1). In addition to MANOVA, t-tests for repeated measures were used to compare the changes at different stages.

Table 1: Student teachers' change in perceptions and practices in technology integration

Factors	Before ICT intentions (std dev)	End of ICT intentions (std dev)	End of TA practices (std dev)	End of TP practices (std dev)	Wilks' Lambda
ICT as administrative tool	2.83 (.54)	3.00 (.58)	2.29 (.67)	2.63 (.69)	25.93**
ICT as teaching support tool	3.05 (.50)	3.11 (.56)	3.29 (.50)	3.40 (.50)	11.16**
ICT as student learning tool	2.74 (.57)	2.91 (.58)	1.72 (.71)	2.17 (.81)	65.50**

(*p-value < 0.05; **p-value < 0.01)

As seen from Table 1, the means of the three factors showed different changes in the student teachers' intentions and practices in integrating ICT in their teaching. Before the ICT course, their intentions to use ICT as an administrative tool, a teaching support tool and a student learning tool were generally quite positive. After they completed the ICT course, their intentions to use ICT further increased. For ICT as an administrative tool, the means increased from 2.83 to 3.00. For ICT as a teaching support tool, it increased from 3.05 to 3.11. For ICT as a student learning tool, the means increased from 2.74 to 2.91 out of the 4-point Likert scale. T-test analysis showed that the increases in ICT as an administrative tool (t = -2.60, p-value <0.01) and student learning tool (t = -2.52, p-value < 0.01) were statistically significant (see Table 2).

Table 2: T-tests comparisons for preservice teachers' change in perceptions and practices

Factors	Before ICT vs. End of ICT	End of ICT vs. End of TA	End of TA vs. End of TP
ICT as administrative tool	-2.60**	8.39**	-3.51**
ICT as teaching support tool	-0.88	-2.93**	-1.97*
ICT as student learning tool	-2.52**	13.18**	-4.92**

(*p-value < 0.05; **p-value < 0.01)

At the end of their five-week Teaching Assistantship (TA) attachment, their practices changed when compared to their intentions at the end of the ICT course. For ICT as a teaching support tool, it significantly increased to 3.29 at the end of TA ($t = -2.93$, p-value < 0.01). On the other hand, their practices to use ICT as an administrative tool and student learning tool decreased significantly. The means for ICT as an administrative tool decreased from 3.11 to 2.29 ($t = 8.39$, p-value < 0.01) and for student learning tool from 2.91 to 1.72 ($t = 13.18$, p-value < 0.01).

At the end of the ten-week final Teaching Practice (TP) attachment, their practices increased significantly for all three factors when compared with their practices during their TA attachment. Use of ICT as an administrative tool increased from 2.29 to 2.63 ($t = -3.51$, p-value < 0.01 as a teaching support tool from 3.29 to 3.40 ($t = -1.97$, p-value < 0.05) and as a student learning tool from 1.72 to 2.17 ($t = -4.92$, p-value < 0.01). The results showed that the student teachers had more opportunities to practise ICT integration during their TP as compared to during their TA attachment.

At the end of each survey, seven items were included to ascertain information about the student teachers' overall attitude towards ICT integration to compare if there were any changes in their attitude before and after the ICT course, at the end of TA and TP attachments. As can be seen from Table 3, the overall attitude towards the integration of ICT in teaching was very positive. The means ranged from 3.20 to 3.30 at all four data collection points on the 4-point Likert scale. Even though there were significant decreases in their practices in integrating ICT as an administrative tool and student learning tool during their TA attachment, their attitude towards ICT integration in teaching remained positive. MANOVA results also showed that there were no significant changes in their attitude from before the ICT course to the end of the TP attachment.

Table 3: Student teachers' attitude towards ICT integration in teaching

Factors	Before ICT	End of ICT	End of TA	End of TP	Wilks' Lambda
Attitude towards ICT integration	3.30	3.20	3.27	3.27	1.12

Discussions and Conclusion

The purpose of this study is to investigate the development of student teachers' intentions to integrate ICT in their future teaching before and after their ICT course and their practices in integrating ICT during their five-week TA and ten-week TP attachments. Exploratory factor analysis showed that the 22-item survey was categorized into three main factors: ICT as administrative tool, ICT as teaching support tool, and ICT as student learning tool.

Changes in student teachers' intentions before and after the ICT course

The student teachers' intentions to use ICT as an administrative tool and as a student learning tool increased significantly after they completed the ICT course. The increases may be because they gained more pedagogical knowledge about how to use ICT in the classrooms from the course. The student teachers were exposed to student-centred pedagogies such as problem based learning and collaborative learning, and also how to integrate ICT tools to promote such pedagogies in their teaching. They gained hands-on experience in using ICT tools such as WebQuest, Web 2.0 tools, and Interactive Whiteboards during the course. They were also required to design student-centred learning activities and integrate ICT tools into those activities. These learning experiences could have resulted in the increase in their intentions to use ICT as a student learning tool at the end of the course. Student teachers were not taught how to use ICT as an administrative tool. However, they were exposed to the use of ICT tools to support administration through their course instructors. For example, the instructors used a Learning Management System and email to communicate with the students on a regular basis. As a result, the student teachers were able to learn from what the instructors practised during the course (Wang, Ertmer, & Newby, 2004).

For the use of ICT as a teaching support tool, the increase at the end of the ICT course was not significant. This could be because the emphasis of the ICT course was not to use ICT as a teaching support tool. The new generation of student teachers tend to feel comfortable using ICT and their ICT skills level was already high to begin with (Markauskaite, 2006). As the participants of this study were relatively young, many of them would have seen their teachers using technology to support teaching when they were students. As a result, it is not surprising that the student teachers' already intended to use ICT as teaching support tool before their ICT course, and thus their intention remained high after the ICT course, resulting in no significant increase in their intention to use it as a teaching support tool.

Changes in student teachers' intentions after the ICT course and practices after the five-week TA attachment

There was a significant increase in their practices in using ICT as teaching support tool, which showed that during the five-week TA, the student teachers were able to use ICT to present complex information, support their explanations of concepts and capture students' attention. On the other hand, their practices in using ICT as an administrative tool and a student learning tool decreased significantly. One of the reasons for the decreases could be because of the limited time for teaching. During the five weeks TA attachment, student teachers started to co-teach with their cooperating teachers only in the last three weeks. As a result, they did not need to handle much of the administrative work. When they started to teach, they may not feel comfortable to use ICT to conduct collaborative learning activities as they were only getting to know their students. Studies have shown that beginning teachers focused more on their own needs (e.g., completing the syllabi) rather than on the students at the beginning years of teaching (Gilles, Cramer, & Hwang, 2001). Therefore, it is not surprising that the student teachers shied away from integrating ICT into more student-centred learning activities during the TA attachment.

Changes in student teachers' practices between the end of TA and the end of TP

The student teachers' practices significantly increased in all three factors during the ten-week TP attachment when compared to their practices during the five-week TA. As the TP was longer than the TA attachment and student teachers were responsible for teaching 20 – 24 lessons per week independently, they had more opportunities to interact with their students and integrate ICT into their teaching in various ways.

The results of the study showed that student teachers' intentions to integrate technology remained high before and after their ICT course. Their practices in using ICT during their five-week TA decreased significantly, which could be because of the lack of time and opportunities to use ICT and to interact with their students. As they gained more autonomy in the classrooms and had more time to explore ICT resources and to interact with students during their TP attachment, their practices in using ICT as teaching support tool, student learning tool and administrative tool increased significantly. Some qualitative information was collected from selected participants through focus group interviews to find out the reasons for the student teachers' changes in intentions and practices. This information is being analysed and findings will be shared during the presentation at the conference.

Lecturer engagement in the use of interactive tools in learning management systems. A Swedish case study.

Michael Christie
Education Department,
Stockholm University, Sweden

Ramon Jurado Garrote
Centre for learning and teaching,
University College of Borås, Sweden

Abstract: In this paper the authors argue that although Higher Education researchers have been largely responsible for the creation of the Internet, university lecturers have been far less innovative and active in their use of this form of Information Communication Technology (ICT). To support our case we use our own research to show the manner and extent to which a Learning Management System (LMS) is used by a sample of teachers from an Engineering Department in Sweden. We also analyze the use of interactive LMS tools by lecturers who undertake staff development courses. The teachers in our two samples make very little use of online asynchronous discussions (OADs) either as teachers or as students. We use logic and the literature to explain this phenomenon and make some recommendations for improving the scholarly, innovative and pedagogical use of LMS in both staff development and mainstream university courses.

Keywords: Learning Management Systems; blended learning; evidence-based practice.

Higher Education and the Internet

In chapter two of a recent book called *Viral Loop. The power of pass-it-on* (2010) Adam Penenberg inadvertently shows the extent to which university researchers affected the development of the Internet. Paul Baran, who worked for the Rand Corporation, is credited with conceiving the idea of an Internet when he suggested it in 1959 as a robust communication network for US military commanders. However it was university researchers, students and graduates, who created a functioning, searchable Internet. In the early1970s Vin Cerf (a Stanford university researcher) and Bob Kahn from UCLA designed the transfer control protocol (TCP) and the Internet protocol (IP) that facilitate online file transfers. They baptized this new information communication system 'The internet' and in 1992 founded the Internet Society. Tim Berners-Lee, a physicist, created another series of protocols that made it even easier for academics to exchange research papers with colleagues around the world. Marc Andreesen, a computer science student, together with Eric Bina created the first effective web browser (Mosaic) in 1993. Andreesen's mission was to make the Internet more useful for a wider public, since, for its first twenty years, it was mainly the domain of university researchers. University researchers continue to be both active and creative in their the of the Internet and ICT. In this paper we argue that university teachers have been less engaged, especially in their use of LMS, and in particular, the interactive tools within LMS such as online asynchronous discussion (OAD) forums.

The use (or lack of use) of interactive tools in LMS

The first case study was carried out in 2005 and published by Garrote in 2006. Garrote investigated the extent to which lecturers in his department made use of different tools in a LMS called WebCT. He was responsible for both the technical maintenance of the system and for providing pedagogical advice on the use of the system. Although introducing the system had been expensive, management felt its use might be one way to arrest a worrying drop in new enrollments and the failure of many students to complete their studies. A similar drop was noted in the United States and the use of ICT was seen as one possible way to avert the problem (Klobas & McGill, 2010; Paulsen, 2003; Weaver et al., 2008; Hopperton, 1998). Irwin and Berge (2006) argued, for instance, that well-run online forums could help create communities of learners where individuals could meet for both scholarly and social purposes.

In his 2005 investigation of LMS use at the University of Borås (UB) Garrote developed a spreadsheet which enabled him to examine 107 courses that were given at the school of Engineering. What Garrote and other researchers have found is that interactive tools, such as asynchronous LMS are under used compared with tools for distributing documents. Teachers for the most part use LMS to upload course programs, required reading and PowerPoints of their lectures (Bongalos et al., 2006; Garrote & Pettersson, 2007; Phillips, 2006). One might expect that as lecturers became more familiar with a LMS and how it was used they might be inspired to begin to use it in a more interactive and creative way. It seems, however, that the pattern noted in 2005 deteriorated over the next 5 years and that LMS use, instead of improving in terms of quantity and quality was used less interactively in 2010 than in 2005 – often by the same teachers (Garrote, Pettersson and Christie, 2011, under review).

The results of the case study undertaken at the University of Borås in 2005 and the longitudinal comparison carried out in 2010-11 exemplify findings from other research. A number of researchers show that high hopes were held for the pedagogical use of LMS in both compulsory and non-compulsory schooling (Blin & Munro, 2008; Bush & Mott, 2009; Findik et al., 2010; Ubell, 2000; Wilson, 2004; Brill & Galloway, 2007; Browne et al., 2006; Czerniewicz & Brown, 2009; Marshall, 2004) but that in the university world, at least, these hopes are still to be realized. Today, many lecturers continue to use a LMS as a means to distribute documents. The failure to use LMS more pedagogically is hard to explain, as is the resistance of many lecturers to embrace new ways of reaching and engaging students via digital media. According to some researchers more staff training is required in order to change this lack of insight and unwillingness to change one's practice (Blin & Munro, 2008; Selwyn, 2007).

Our second case study looks at what happens when teachers themselves are in the position of students. Do they engage in OADs when encouraged to do so? This case study is based on an analysis of OADs in a course for supervisors of PhD students that was run twice a year for researchers at Chalmers University of Technology. The first author has given 10 such courses between spring 2006 and autumn 2010. In total 320 supervisors have taken the course. They attend four full days of course work in addition to doing take-home tasks, for example interviewing an experienced supervisor and posting a transcript of the interview on an OAD. They are asked to read and comment on one another's interviews prior to discussing them in small group work at the course itself. They are also asked to post, on another discussion forum, a proposal concerning an aspect of their supervision that they wish to improve on. The idea is that they will carry out some sort of simple research – by using the internet for example, or by surveying colleagues in the course or in their own departments. The final report, which is discussed in small groups on the last day, must also be posted on the 'Improving my supervision' OAD in the last week of the course so that colleagues can provide and receive feedback on all the projects.

The courses are given in English to non-native speakers. Course delegates include both Swedes and other nationalities. A third OAD is made available on the course site and is aimed at mutual support for the writing of conference abstracts. This last OAD is offered as a service by the course facilitator who is a native English speaker. Those who post abstracts are guaranteed feedback from the course facilitator but everyone is encouraged to read the abstracts and contribute by offering editing and other advice – in other words this OAD is a type of peer review forum (Lefoe et alia, 2009). Posting an abstract on this OAD is not a required part of the course. Course participants are aware of the course design before they apply and are specifically told about the face-to-face discussions and OADs in the letter of welcome that is sent out informing them of their acceptance into the course. In other words, commenting on each others' texts in the OADs and joining in an online discussion about them, is strongly encouraged but does not affect whether or not one passes the course.

An analysis of activity in these OADs from 2006 to 2011 reveals a common pattern. Apart from one or two cases where delegates are forced to drop out off the course or postpone completing it until a later date, all participants upload their interviews as well as their proposal and final report for their mini projects. Comments and discussion of interviews and projects varies from year to year but on average there is no more than two persons per course (2 in 32 or just over 6 %) who actually engage in the proposed online discussion. The chance of this happening is far greater for the 'Interview' OAD which must be posted before the course begins, than for the 'Improving my supervision' OAD.

Explaining the lack of use of LMS by university teachers

Our case studies and current literature in the area indicate a number of reasons why university lecturers (even when engaged as students in a staff development course) so not use OADs. When teachers in higher education are asked to identify barriers to the use of educational technology lack of time and lack of support are the most common answers (Al-Senaidi et al., 2009). The lecturers' perceived shortness of time and lack of support is directly linked to the perceived ease of use. The most plausible explanation for the difference in using these two functions is that teachers perceive the consequences of distributing documents to be far less time consuming and intellectually demanding than setting up a discussion forum that may need to be monitored or assessed (Lonn & Teasley, 2009). To commit oneself to a well-run discussion forum not only depends on one's perception about how much time it will take, but also on how one perceives the usefulness of such a teaching and learning method. If lecturers believe that a non-monitored discussion will result in students pooling their ignorance they are unlikely to use it. If they think that monitoring a discussion will not result in enough teaching and learning benefits to warrant the invested time, they will also be wary of using such a tool. On the other hand if they think that online asynchronous discussions (OADs), whether monitored or not, could contribute to the learning of subject-specific and generic competencies, then there is a greater chance that they will be willing to invest time in setting up and maintaining an OAD. Lecturers whose approach is mainly teacher-centered and whose principal concern is how a tool may facilitate his or her work within a set frame of teaching practices and institutional traditions, will be less likely to use OADs. Those who consciously or intuitively practice a more student-centered and active learning approach, on the other hand, are more likely to commit the time and effort to set up and monitor OADs. The latter approach will take more time initially but may have, according to the literature, substantial long-term benefits for the students by creating a community of practice and promoting collaborative learning (Ladyshewsky & Gardner, 2008).

Whether a lecturer uses a discussion forum or not usually depends on the lecturer's perception of the OAD's contribution to a specific course. If the OAD is considered to be sufficiently useful there is more chance the lecturer will commit time and effort to running it well. Murphy argues that 'the higher-level processes related to collaboration in an online asynchronous discussion (OAD) may need to be more explicitly and effectively promoted in order to counteract a tendency on the part of participants to remain at the level of individual rather than group or collaborative effort' (Murphy, 2004. abstract). Although more research is needed, it seems that time and effort spent on introducing and supervising an OAD can ease the lecturers´ workload in other areas. For example the use of OAD may decrease the demand on time needed for counseling students, since they are able to exchange information and ideas about the course as part of the OAD experience.

Since so much depends on how teachers perceive the usefulness of OADs, convincing arguments that demonstrate their benefits for the development of both specific and generic competencies, are important. In most educational institutions both lecturers and students are under pressure to produce results. In an environment where most teachers realize that good research is more likely to benefit their career than good teaching, putting effort into developing a well functioning OAD may be undervalued. Similarly, if students are strategically focused on activities that will result in the best grades, time spent on an OAD that does not give a grade or improve their assessment chances may be seen as irrelevant. As Lonn & Teasley (2009 p. 92) point out 'As long as students fail to see the relevance of interactive tools for their learning or for instructors' teaching, they are likely to continue to view IT as merely a quick and accessible means to retrieve course documents and get messages from instructors'. The use LMS to distribute documents or send out notices to students are functions that replicate the more onerous tasks of copying lecture notes or emailing lists of students. Using them is often saves time and paper. The use of OADs is another matter. In traditional courses in engineering education, for example, there is very little interaction between lecturer and student. It is the teaching assistant (often a PhD) who works with smaller groups of students in the tutorial room or laboratory. Lecturers who are unused to dealing with group discussion in the real world are not necessarily the best at dealing with them in a virtual world. Lecturers need both technical and pedagogical support if they are to make better use of OADs. For both teachers and students in Higher Education the way forward in the more active and productive use of LMS and OADs is to weave continuous assessment into the use of such tools. This is important not only in the areas of subject specific knowledge, skills and attitudes but also in the generic competencies that we aspire teach.

‘Because I said so’: A Teacher-Centred Approach as a Scaffolding Technique to Accommodate International Distance Learners in a Student-Centred Environment

Valeri Chukhlomin
Center for Distance Learning
State University of New York Empire State College

At the SUNY Empire State College’s Center for Distance Learning (CDL), the majority of students come from the State of New York, whereas international distance learners were historically a tiny fraction. This is currently being changed, with the ongoing rebranding of the College as New York’s Open University. Seeking to enhance its curriculum to better accommodate international distance learners, CDL has engaged in the development of bridging bilingual/bicultural courses such as “International eLearning Skills for Russian Speaking Students”. The course designed and taught by bilingual/bicultural professors helps students overcome linguistic, cultural, technological, and organizational barriers and adapt to the North American learning environment. In this paper, I will briefly describe the project, problems discovered and solutions found, including the use of scaffolding techniques, such as teaching-centred pedagogy.

Keywords: international distance learning, virtual acculturation, teacher and student centredness

Introduction

SUNY Empire State College (ESC) was established in 1971 to provide adult learners and working professionals with an opportunity to earn associate, bachelor`s and master`s degrees from the State University of New York (SUNY). The College employs a mentoring approach where students design individualised degree programs under guidance of faculty mentors. The College’s Center for Distance Learning (CDL), a founding member of the Sloan-C consortium, is a national leader in online learning. The Center employs LMS “ANGEL”, video-conferencing tool “Elluminate”, lecture capturing software “Accordant”, and widely uses Web 2.0 tools and virtual worlds. Historically, CDL has been primarily serving domestic students. This is currently being changed, with the ongoing rebranding of the College as New York’s Open University. To promote and coordinate global learning, CDL uses an international distance learning (IDL) faculty group. Among other things, the IDL group is involved in designing and developing dual degree programs with foreign universities. Students from partner universities, similarly to domestic students, can take one or several online courses [=units] at CDL or even assemble and complete an entire undergraduate degree program. Until recently, international students, being a small minority in CDL courses, have been receiving equal treatment with domestic students under the assumption that if they wish to study at an American online college, they (or their home institutions) should be fully responsible for their preparation. A study of joint programs between CDL and three Russian universities (Chukhlomin, 2009; 2010a; 2010b) revealed that despite the efforts undertaken by partner universities incoming Russian students weren't sufficiently prepared for immersion into the virtual environment of CDL. To better accommodate international distance learners, the IDL group suggested using bridging bilingual/bicultural courses; this approach was described by Chukhlomin & Deshpande (2011) as the "3B Framework". The central idea of this approach is to design educational planning studies helping new coming international students to transition into the new environment by using scaffolds, such as bilingual/bicultural instructors, materials, discussions with peers, and employing teaching methodologies that are more familiar to students.

Barriers to International Distance Learning

Since 1998, SUNY ESC has been running a dual degree project in partnership with Omsk State University, a large nationally accredited Russian institution, located in Siberia. Initially, the project employed an international distance learning (IDL) format. To earn a SUNY bachelor's degree in business, Omsk students were supposed to transfer up to 75% credits obtained at their home institution, while completing remaining 25% credits at ESC through IDL. Notwithstanding substantial organizational efforts undertaken by both sides in 1998-2003, this initial program design was found not feasible. Omsk students were facing significant and sometimes insurmountable barriers that included: 1) organizational barriers; 2) communication barriers associated with language, culture, and differences in academic systems; 3) insufficient subject matter knowledge and skills; 4) a lack of experience in studying at a distance. To alleviate barriers, the initial program design was significantly changed; in particular, the following improvements were made: 1) instead of advanced level courses, only lower level American courses were offered through IDL; 2) a blended learning approach was employed where American professors annually travelled to Russia to conduct face-to-face classes; 3) advanced level American courses were conducted on-site only, through an offshore ESC's unit located in Prague, Czech Republic, where Russian students were required to travel to complete the degree; 4) additional courses taught in English by expatriate faculties were added to the Omsk curriculum. In this largely redesigned form, the Omsk dual degree program was re-launched in 2004; since then it has been successfully producing 12-15 graduates at the bachelor's level and 15-25 graduates at the associate's level every year. In 2010, the improved program design has been successfully replicated by another Siberian university located in Novosibirsk.

Eventually successful, the Omsk and Novosibirsk projects didn't provide a suitable model for online delivery of dual degree programs in Russia, without the need for either students or professors to travel internationally. Meanwhile, with the arrival of new learning technologies, such as Web 2.0 tools, videos, lecture capture, and videoconferencing, some of the barriers to IDL have apparently become easier to overcome [Maloney, 2007]. To investigate whether the new ESC's virtual learning environment has made it easier for international students to study online, the IDL faculty group initiated a series of new projects with Russian universities. In particular, in 2007 ESC engaged in a new project with a polytechnic university located in Tomsk, Siberia. Tomsk University was interested in replicating the initial design of the Omsk project where some of the students studying in Tomsk full time would be able to simultaneously complete a SUNY bachelor's degree through IDL. For this project, Tomsk University obtained funds from the Russian government. After conducting several pilot courses in 2007-08, the partners discovered that, similarly to the Omsk case, Tomsk students were experiencing serious problems with IDL. Namely, they: 1) found it difficult studying without face-to-face interactions with professors; 2) were mostly exposed to a teacher-centred pedagogy; 3) were largely not familiar with the concepts and terminology used in advanced level CDL courses; 4) were lacking some critically important skills, including English academic writing, communication skills, teamwork, and time management skills. Also, they were found to be: 5) not familiar with the American online classroom, for example, reluctant to participate and inexperienced in debating things; 6) reluctant to communicate with CDL technical personnel and student services; 7) not used to using the information provided for students on the ESC student website; 8) not familiar with the contextual information used by American course developers and instructional designers to design CDL courses that had been developed with primarily domestic students and adult learners in mind. On the other hand, it was also noticed that the Tomsk students very quickly learned how to use LMS "Angel", synchronous video tools and other learning technologies (Chukhlomin & Deshpande, 2011).

Virtual Acculturation

In recent time, the theme of virtual acculturation has received a growing amount of attention of researchers and practitioners from around the world (http://www.acculturation.nl). A literature on virtual acculturation provides theoretical foundation for the design and development of bridging courses aimed at alleviating barriers to IDL. Acculturation has been defined as "those phenomena which result when groups of individuals having different cultures come into continuous firsthand contact, with subsequent changes in the original cultural patterns of either or both groups" (Redfield et al, 1936. p. 149). Recently, with the advent and increasing popularity of online education in the US and the global context, students from various countries are attracted more and more towards a US online degree (Pittinsky, 2003). With an increase in diversity in online classroom, there is a need to help learners acclimatize to the complexity of the virtual environment and to develop a culturally responsive pedagogy helpful to all learners (Gollnick & Chinn, 2002). Particularly, in an online context researchers have reported high stress among foreign international students exposed to their first virtual experience (Kyungbin *et al*, 2010). Bridging courses if designed adequately help learners successfully assimilate to the foreign educational culture and context. Literature has often highlighted the importance of such courses for incoming foreign students and has called for research in this area (Peelo & Luxon, 2007; Evans & Northcott, 1999). Particularly, in an online context, this becomes extremely important for international learners as they do not have the opportunity to actually "see" and experience the host culture. The benefits of such courses are significant. For instance, such courses provide students with an opportunity to learn about foreign country's educational setup and requirements. In addition, such courses provide students with cultural understanding and norms of the host country (Peelo & Luxon, 2007). When dealing with homogenous bilingual communities and student groups, the use of the learners' native language and bilingual instructors was found to have great potential (Taggart & Martinez, 2002; Werner-Smith & Smolkin, 1995).

International eLearning Skills: a bridging bilingual/bicultural course

This online study developed in 2008 serves as a bridging course aimed at providing remotely located, Russian-speaking students with a smooth way to transition into the American virtual learning environment. The main objectives of the course are to: 1) provide Russian-speaking students with an introduction to American culture and American education; 2) help them learn how to navigate the CDL's virtual learning environment; 3) learn how to use virtual resources, conduct research and present results; 4) learn about student-centered environments and introduce "the American way" of online discussions, collaborative teamwork, reflecting learning, using technology, finding help. The 8 week course is conducted by bilingual/bicultural faculties in LMS "ANGEL", with the use of lecture capture, video conferencing, e-portfolio, wikis, blogs, and a bilingual study guide. By the end of the course, students are expected to learn how to: 1) select and independently register for online courses at CDL; 2) make necessary arrangements for transferring credits and ordering textbooks; 3) use appropriate technologies and helpdesk; 4) use virtual library and style guides; 5) access the ESC-owned island in 'Second Life'; 6) master ESC-specific tools like 'Degree Planner'; 7) develop the first draft of their individual degree plan and write a rationale essay; 8) use 'Smarthinking' and peer tutoring support; 9) use wikis and e-portfolios. In addition, students are introduced to academic writing, library helpdesk, and peer tutoring and virtual career planning resources. Even more importantly, they are guided to develop (or, at least, create awareness of) such critically important skills, as communication, time management, self-guidance, and teamwork.

In 2008, a group of 8 Russian students took a pilot version of course and since then the course has been regularly offered by CDL. In 2009, Tomsk University sponsored a group of 10 professors to take the course as part of their faculty development training. In 2010, the course template was used to conduct professional development courses for groups of Russian-speaking educators sponsored by the Open Society Institute.

On the use of scaffolds

Scaffolding, grounded in Vygotsky (1978), is often seen as a conceptual framework for learners' support in online courses (Ludwig-Hardman & Dunlap, 2003; McLoughlin & Marshall, 2000). Also, scaffolding is found to be a useful technique in international education (Evans & Northcott, 1999). As an instructional tool, a scaffold enables a learner to solve a problem, carry out a task, or achieve a goal that she cannot accomplish on her own; this tool can be easily removed when no longer needed (Puntambekar & Hubscher, 2005; Wood et al, 1976). In the context of international distance learning, scaffolding can be organized with the help of bilingual/bicultural instructors and peers, and also through the use of bilingual instructional materials in the form of books, articles, video lectures, presentations on "YouTube", etc.

In the above mentioned course, all announcements and most of the content guides are provided in Russian, including an introductory video lecture captured with the use of 'Accordent'. In the opening 3 weeks of the course, the instructor who teaches the course should establish rapport with the students by following a 'traditional Russian' teaching style as if the course were taught in their home university. In other words, the instructor is obligated to tell the students what exactly they should do, very much like it is normally done in Russian universities. During that time, students learn about the use of LMS 'ANGEL', the College website, a virtual library, a videoconferencing tool 'Elluminate'. Also, they read about American education, classroom structure, the differences in learning and teaching styles between Russia and the U.S., and expected behaviors in an "all American" online setting. Then, in the middle of the course, the instructor is required to switch his/her communications with the students to mostly English using Russian as a means of clarification only. When communicating in English, the students are required to practice learning behaviors "as in the US". During that time, the instructor's role is to explain how online courses are taught in the US and to demonstrate examples.

Conclusion: from teacher-centred to student-centred learning

International learners studying at CDL remotely can simultaneously be exposed to very different pedagogies; to succeed in both the American college and their home institution, they should be provided with assistance. Students from predominantly teacher-centred environments like Russia (Burry-Stock et al, 2001) tend to be reflective theorists (Mitsis & Foley, 2009); they usually expect their teachers to tell them where to go and how; at home, this strategy serves them very well. At the same time, in a student-centred environment like CDL, they are expected to take the lead. But how can a student do this if she or he has never done it before? The problem is aggravated by the fact that learning is taking place at a distance; in a foreign language; in a new cultural and academic environment. Perhaps, it is a logical and natural solution for teachers to lead the way one last time and invite students to follow just because the teacher said so.

The CAT amongst the pigeons: A reflective framework approach to personalised professional development in open, flexible and networked learning.

John Clayton
Emerging Technologies Centre
Waikato Institute of Technology
New Zealand

Richard Elliott
Emerging Technologies Centre
Waikato Institute of Technology
New Zealand

Reflective-frameworks are designed to assist educators to critically reflect on their professional practice. In essence individuals make meaning from their professional experiences in relation to accepted best-practice. This paper will explore the use of a reflective-framework in open, flexible and networked learning. The development of a competency assessment tool ,the CAT, to help educators reflect on their current use of e-Learning applications and the pedagogy of their practice, is decribed. By working through the CAT individuals can identify areas of strength and examine areas requiring development. The result of this critical evaluation is the generation of personal learning plan (PLP) in the effective use of e-learning. How the reflective framework operates as an *empowerment* approach to professional development is explained in detail. This paper argues that the use of the CAT extends the repertoire of teaching skills, improves professional practice and ultimately enhances the learning environments of learners and teachers.

Keywords: personal learning plans, professional development, reflective practice

Background

Historically, educators in the tertiary sector have generally been employed for their depth of knowledge of a specific discipline rather than their expertise in teaching practice. Success was measured by learner acquisition of discipline knowledge and mastery of identified skills. However, driven by fiscal restraints and the need to remain globally completive in an increasingly knowledge-based, networked world, a number of Governments have introduced a raft of educational reforms. In the New Zealand tertiary education sector these reforms have focused on firstly, improving performance and efficiency ensuring more learners from a broader ethnic, cultural and educational background can complete higher qualifications at an affordable cost (Maori Tertiary Reference Group, 2003: Ministry of Education, 2010) and secondly, increasing the organisational integration of e-learning systems and Information and Communication Technology (ICT) applications for administrative purposes and teaching and learning (Ministry of Education, 2004). As a consequence of these reforms, tertiary institutions have widened entry criteria and greatly increased enrolments. In essence they have created a cohort of culturally diverse learners that hold multiple-views of phenomena and has multiple-meanings for words that have proved to be useful to them in making sense of the world that surrounds them (Clayton, 2009). In the learning environment created by this cohort, it is an expectation educators will adapt teaching strategies and content to meet the educational, social and cultural needs of this diverse audience (Zimmerman & Schunk, 2001). Educators can no longer rely on their depth of discipline knowledge, they need to critically reflect on their current professional practices and from this reflection identify how they can extend their repertoire of teaching skills. An identified risk inherent in this self-reflective approach is the dependence on individual educators having the requisite ability to meaningfully reflect upon their current professional practice and have sufficient depth of pedagogical knowledge to then create a personalised learning plan. To mitigate this risk, it is argued a self-reflective framework approach, where educators are able to make meaningful connections between their current professional practices and established standards in teaching and learning, is required (Clayton, Elliott, & Saravani, 2009).

Context

The rapid advancement of Information and Communication Technologies (ICT) has been referred to as the third revolution in the public dissemination of knowledge and in the enhancement of teaching and learning. The first revolution being the creation of a written language and readable records and the second the development of movable type and the publication of books (UNESCO, 2008). To participate successfully in this new "knowledge age" individual New Zealand educational institutions and successive Governments have increased their investments in infrastructure, hardware and software applications (Ham, Gilmore, Kachelhoffer, Morrow, Moeau, & Wenmoth, 2002). However, institutions and governments are aware physical technologies on their own will not meet national goals. They acknowledge that the level of competence and confidence of staff in the educational use of ICT will directly impact on the capacity and capability of institutions to positively engage their learners in ICT-supported learning environments (Clayton, Elliott & Saravani, 2009a).

In 2010 the Waikato Institute of Technology recognised the need to provide professional development (PD) in ICT for staff to meet both the needs of its increasingly culturally diverse student population and institution aspirations. The Certificate in Open, Flexible and Networked Learning (COFNL) consists of 5 modules based on identifiable Unit Standards registered with the New Zealand Qualification Authority (NZQA, 2011). Basing the certificate on these registered standards ensured the institute was following best national practice and aligned institutional PD delivery with national goals.

The CAT: A Reflective Practice Framework

The concept of reflection has been widely debated in educational circles for a number of years (Kreber, 2004: Brockbank, & McGill, 2007). To advocates of reflective practice, deep-learning is dependent on individuals making meaning from their experiences through reflection (Sugerman et al, 2000). To engage participants in reflective practice and to aid them in making connections between identified pedagogical standards in ICT and their previous experiences, a self-reflective competency assessment tool (The CAT) was created for prospective candidates of a certificate in Open, Flexible and Networked learning (COFNL). The CAT was designed to enable prospective candidates to assess their current competencies against defined standards. The CAT interface provides the prospective candidates with a series of statements relating to each of the five modules within the COFNL. The statements within each module are classified within three categories: Understanding, Evidence and Moderation. The three categories are defined below:

- *Understanding:* This division prompts the learner to reflect on their personal knowledge of the defined area of open flexible and networked learning specific to an individual module.
- *Evidence:* This division asks the prospective candidate if they can provide evidence of their understanding of the defined area of open flexible and networked learning, specific to an individual module.
- *Moderation:* This division asks the prospective candidate how the evidence they indicate they can provide, has been evaluated.

Candidates are asked to reflect upon and then respond to individual statements within each category using a 'drop-down' menu. The menu has four possible responses to each statement: Disagree, Partially agree, Agree, Strongly agree. The CAT interface is illustrated in figure 1 below.

Examine the relationships between participants in OFNL.	
Understanding	
I have a good understanding of the relationships (such as direct, indirect, active, passive, interactive, independent, and interdependent) that exist in open, flexible and networked learning environments.	Partially agree
I have evaluated the impact different relationships between participants in OFNL (such as direct, indirect, active, passive, interactive, independent, and interdependent) have on student learning in different contexts.	Strongly agree
Evidence	
I can provide digital evidence of my understanding of the relationships (such as direct, indirect, active, passive, interactive, independent, and interdependent) in open, flexible and networked learning environments.	Partially agree
I can provide digital evidence of how my understanding of the relationships between participants in OFNL (such as direct, indirect, active, passive, interactive, independent, and interdependent) has been used in my practice in different contexts.	Agree
Moderation	
My understanding of the relationships (such as direct, indirect, active, passive, interactive, independent, and interdependent) in open, flexible and networked learning environments has been peer reviewed.	Select
Practical application of my understanding of the relationships between participants in OFNL (such as direct, indirect, active, passive, interactive, independent, and interdependent) has been peer reviewed and assessed.	Select

Figure 1: Categories, statements and responses

Personalised Learning Plans

As candidates progress through the CAT, their answers affect the indicator colour on the main index page. The indicator colours are based on the familiar "traffic light" theme;

- *Red:* This indicates to the candidate they have limited knowledge and/or experience of the identified standards. It also indicates how these limitations can be addressed.
- *Yellow:* This indicates the candidate has some knowledge and/or experience of the identified standard. It also indicates how this existing knowledge/experience can be built upon.
- *Green:* This indicates to the candidate that they meet the requirements of the identified standard. It also indicates how they can continue to build knowledge and experience in other areas.

As the prospective candidate progresses through the categories and statements for each module, their responses provide a pictorial 'carpet'. This visual carpet enables individuals to select, which module(s) they need to review, which competencies they need to develop, what evidence they need to provide and how they should evaluate their practice. The reflective framework and visual carpet is illustrated in figure 2 below.

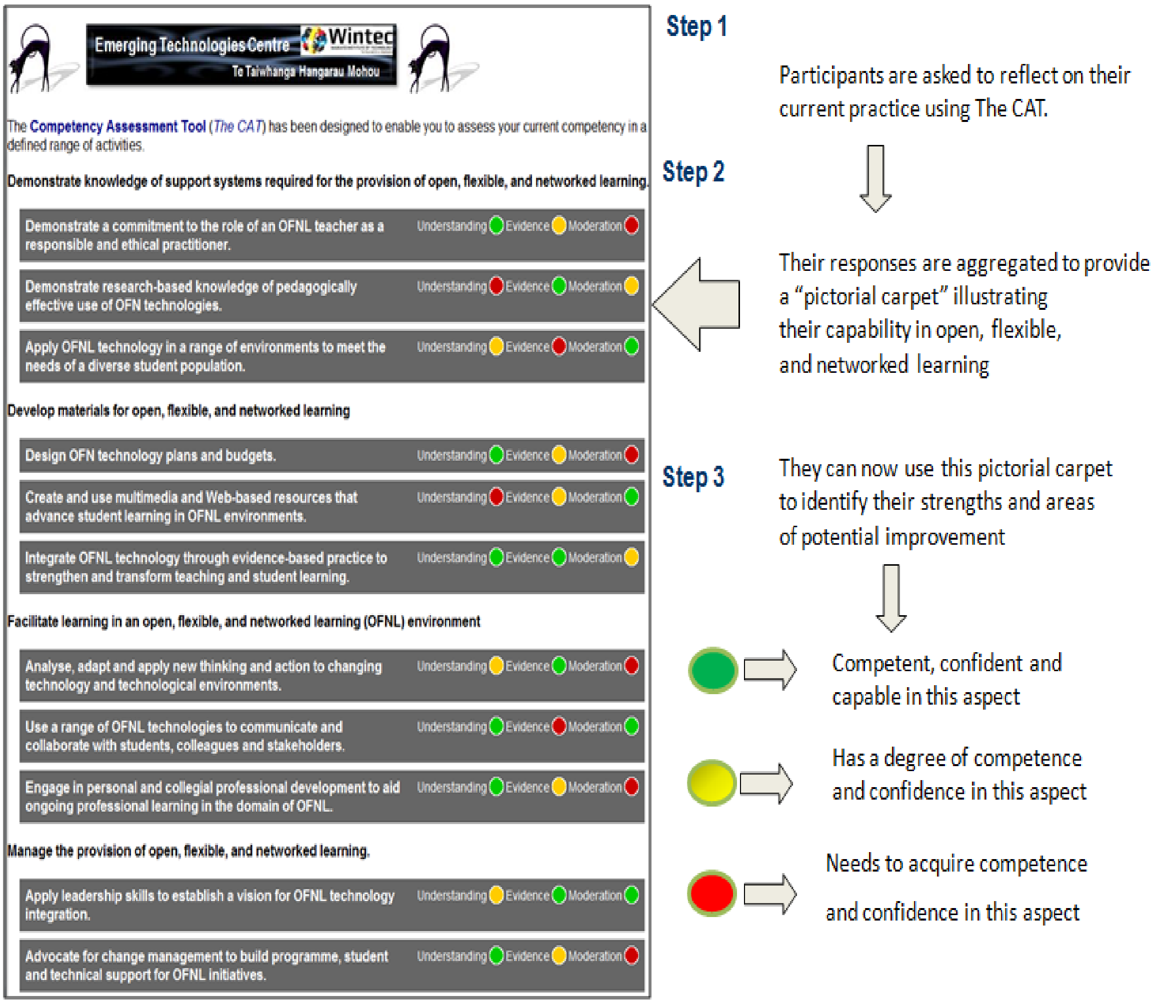

Figure 2: The Cat providing a visual carpet.

The visual carpet produced from candidate engagement with the CAT provides individuals with:

- An assessment of their current knowledge, experience and understanding of individual aspects of the domain.
- An indication of a range of potential points to begin their personalised learning journey, and
- Navigational tips to map a learning route from starting point to intended achievements.

In essence engaging with The CAT assists the learner in the creation of a personalised learning plan (Ward, & Richardson, 2007) enabling them to become self-regulated learners (Zimmerman, 1990).

Discussion and Conclusions

This paper has argued recent reforms have encouraged the creation of diverse cultural cohorts and the integration of e-learning applications in course delivery. As a consequence, educators are now engaging with increased numbers of culturally diverse learners in ICT environments they are unfamiliar with. Educators are encouraged to reflect on their prior experiences, acknowledge the influence of learners' prior experiences on the learning process and engage in the design of learning events to meet the needs of this diverse cohort of students. This requires a fundamental shift in educators' existing perceptions of teaching, learning, the curriculum and the use of e-learning. However, this shift places extra demands upon individual educators. An inherent risk is the dependence on individual educators having the requisite ability to meaningfully reflect upon their current professional practice and have sufficient depth of pedagogical knowledge to then create a personalised learning plan. To mitigate this risk, it is argued a self-reflective framework approach, where educators are able to make meaningful connections between their current professional practices and accepted standards in teaching and learning, is required. This reflective-framework approach enables educators to work independently, manage time effectively, and think self-critically. It empowers them as professionals.

This paper argues the effects of empowerment models of learning, driven by reflective-frameworks such as The CAT will be positive. This approach will enable educators to both make meaning from their experiences and actively learn from engaging in a reflective process.

mLearning: Why? What? Where? How?

Thomas Cochrane
Centre for Learning and Teaching (CfLAT)
AUT University, New Zealand

This paper explores the state of play of mlearning in education. Mlearning bridges pedagogically designed learning contexts, enables learner generated contexts, and content, while providing personalization and ubiquitous social connectedness. The researcher makes a case for the impact of mlearning to act as a catalyst for transforming pedagogy informed by the implementation of over 30 mlearning projects, and reflects upon example implementations of mlearning within a variety of contexts.

Keywords: mlearning, mobile web 2.0, student-generated content, student-generated contexts.

Introduction: Why mLearning?

Worldwide ICT statistics (Acharya & Teltscher, 2010) provide a compelling argument for investigating the potential of wireless mobile devices (WMDs), and in particular mobile phones and smartphones, as these devices have by far the highest ownership of any computing or connected devices (see Figure 1). Figure 1 provides approximate worldwide averages for access to a range of ICT technologies garnered from the International Technology Union 2010 report.

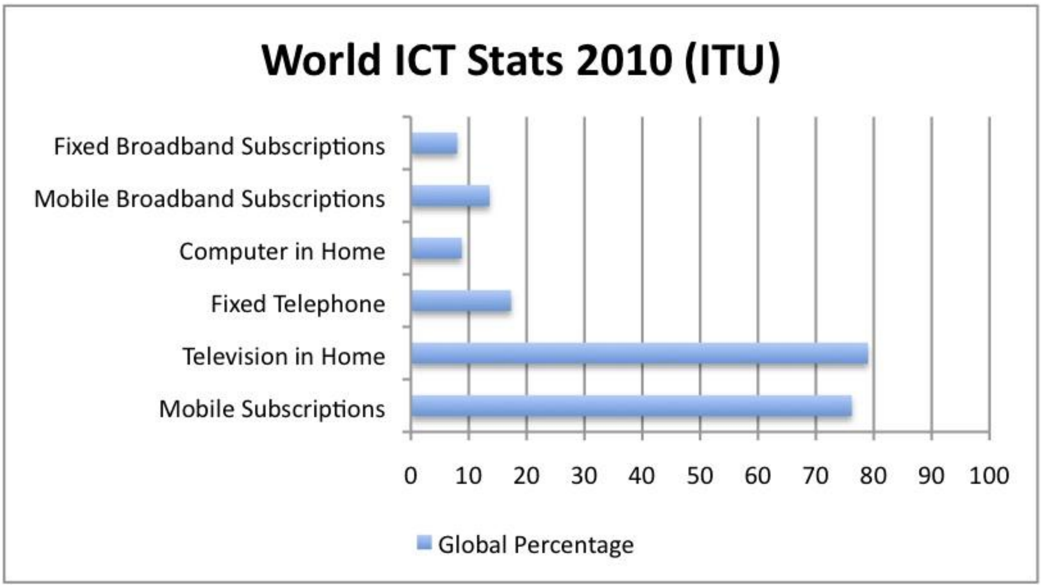

Figure 1: Average World ICT statistics taken from the 2010 ITU report (Acharya & Teltscher, 2010).

The unique potential impact of WMDs on education is founded upon their rise to almost ubiquitous ownership (ITU, 2009) and their primary functionality as ubiquitously connected communication devices. These two characteristics of wireless mobile devices enable their use as disruptive devices to act as catalysts for pedagogical change by mediating student-generated learning contexts and sharing student-generated content as key elements of social constructivist learning or Pedagogy 2.0 (McLoughlin & Lee, 2008). The 2010 JISC mobile review (Belshaw, 2010) concludes that mobile learning presents the potential to drive innovation in education.

> Mobile learning may mean different things to different people, but it is the dialogue that an institution begins with itself, its' staff, its' learners, its' community - that matters. It is certainly not time for 'business as usual'. It is time to define and start driving innovation. (p. 63)

This potential for innovation is both driven and hampered by the rate of change in mobile technologies. Although the rate of change of mobile technology is very high the choice of a pedagogical framework and foundational pedagogical theory can guide the appropriate pedagogical use of future WMD developments. The rise of mobile application ecosystems (for example: the iTunes Store for dissemination of iOS WMD applications and media, the Android Market for Android WMD devices, and the Nokia Ovi Store for Symbian based WMDs) that bridge information, content and productivity with laptop or desktop computing via web 2.0 platforms, has created a mobile learning framework that can be easily appropriated by a wide range of educators without requiring specialist computing skills, creating the potential for mainstream adoption of mlearning in tertiary education. WMDs can be utilized as content creation devices for students' online eportfolios, and for establishing a digital identity that can become a key element of their on-going professional careers. WMDs can also be utilized as communication and collaboration tools within an increasing range of social networking tools. Mobile Learning (mlearning) has moved beyond the realms of fantasy to become a viable platform for contextual learning that bridges formal and informal learning environments in and beyond the classroom. Kukulska-Hulme (2010) emphasises the catalytic nature of mlearning:

> With its strong emphasis on learning rather than teaching, mobile learning challenges educators to try to understand learners' needs, circumstances and abilities even better than before. This extends to understanding how learning takes place beyond the classroom, in the course of daily routines, commuting and travel, and in the intersection of education, life, work and leisure. (Kukulska-Hulme, 2010, p. 181)

It is the ability of mlearning to act as a catalyst for pedagogical change that has interested the author and formed the basis for developing a design framework for mlearning that is based upon a social constructivist pedagogy that enables learner-generated content and learner-generated contexts. Thus rather than being technology centric, the author sees the impact of mlearning in regards to the potential for pedagogical transformation.

> Mobile learning - as we understand it - is not about delivering content to mobile devices but, instead, about the processes of coming to know and being able to operate successfully in, and across, new and ever changing contexts and learning spaces. And it is about our understanding and knowing how to utilize our everyday life-worlds as learning spaces. Therefore, in case it needs to be stated explicitly, for us mobile learning is not primarily about technology. (Pachler, Bachmair, & Cook, 2010, p. 6)

Background: What

One of the key realizations of previous large mlearning projects (for example: MOBILearn) was that it is the learner that is mobile, and the learners interact continually throughout the day facilitated by mobile devices. Therefore focusing on the mobility of the learner is central to mlearning (Sharples, 2010). While technology continually changes, how learners learn and interact, and what educators want our student graduates to be able to achieve is persistent. Mlearning by nature involves interaction with continually changing technologies, but rather than being eventually assimilated into traditional computing, the researcher argues that mlearning is reinventing and transforming computing from a tool to integrating computing into our lifestyles. Two-thirds of the world's population already own and carry a cellphone (ITU, 2009). Mlearning is not just the miniaturization and convenience of portable computing, but is transforming how we conceptualize and interact with computing and our environment, communicate, and create and manipulate information (Cheney, 2010; Pachler, et al., 2010). Mlearning is about ubiquitous social connectivity, instant information access, and enhancing how we view the world through digital augmentation (Cook, 2010a). It is empowering for learners, who can become content and context generators within authentic learning environments (A. Herrington & Herrington, 2006, 2007) rather than simply consumers of transmitted content in classrooms. Additionally, emerging touch and voice interactivity with mobile computing will change our expectations of how learners interact with computing.

Therefore, mobile learning, as defined by the researcher, involves the use of wireless enabled mobile digital devices (Wireless Mobile Devices or WMD's) within and between pedagogically designed learning environments or contexts. Mlearning can support and enhance both the face to face and off campus teaching and learning contexts by using the mobile wireless devices as a means to leverage the collaborative use of web 2.0 tools. The WMD's wireless connectivity and data gathering abilities (for example: photo blogging, video recording, voice recording, and text input) allow for bridging the on and off campus learning contexts – facilitating "real world learning" (Unitec New Zealand, 2010). It is the potential for mobile learning to bridge pedagogically designed learning contexts, facilitate learner generated contexts, and content (both personal and collaborative), while providing personalization and ubiquitous social connectedness, that sets it apart from more traditional learning environments. From an activity theory perspective, WMD's are the tools that mediate a wide range of learning activities and facilitate collaborative learning environments (Uden, 2007). However, the use of

Wireless Mobile Devices (WMDs) as part of the teaching and learning environment requires changes in pedagogy and integration into the teaching and learning processes. Mlearning enables learner-generated content and learner-generated contexts. Figure 2 is the author's Mobile Web 2.0 Concept Map that attempts to represent the interactions between multiple learning contexts and web 2.0 tools enabled by mobile devices.

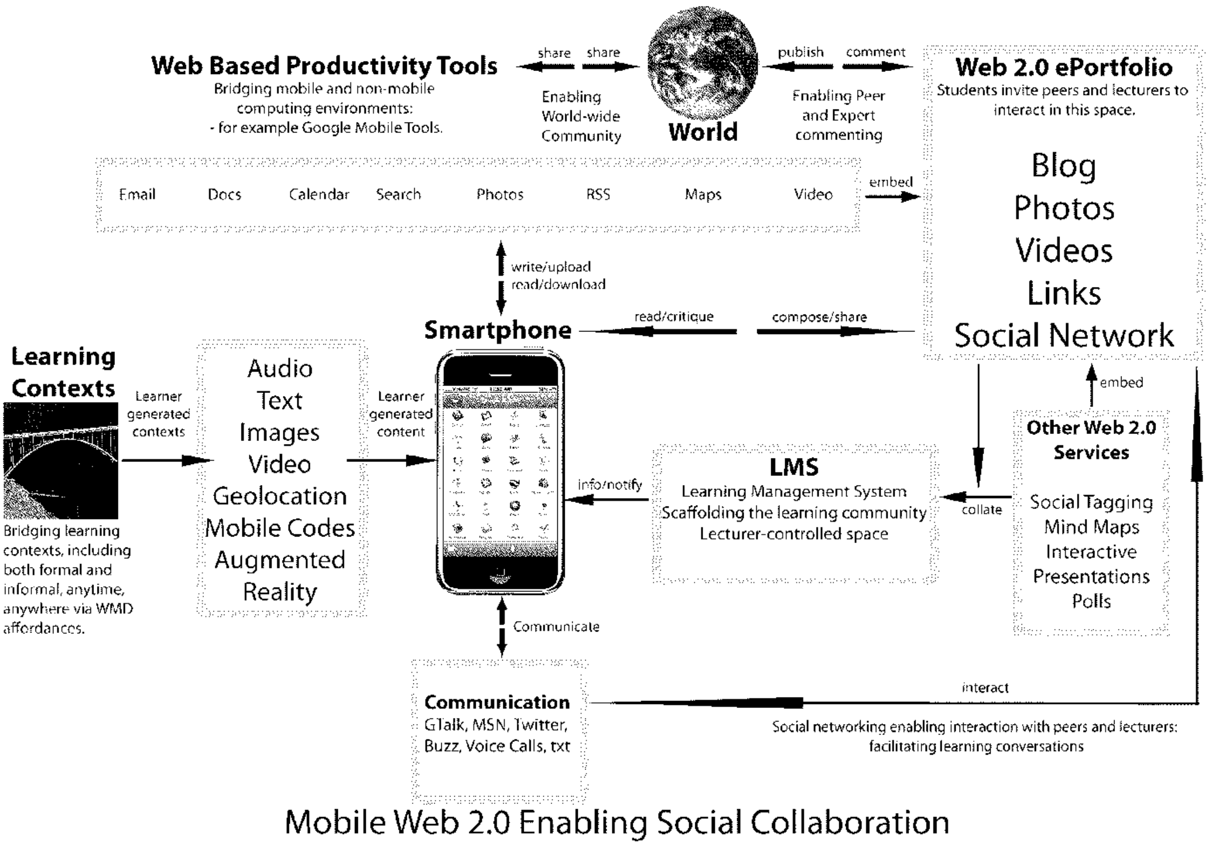

Figure 2: Mobile Web 2.0 Concept Map.

Research Overview: Where

Cook (2009a) and Sharples (2009, 2010) characterize the development of mobile learning research according to three general phases:

1. A focus upon devices (For example: Handheld Computers in Schools (Perry, 2003))
2. A focus on learning outside the classroom (For example: MOBILearn (O'Malley, et al., 2005))
3. A focus on the mobility of the learner (For example: MyArtSpace (Sharples, Lonsdale, Meek, Rudman, & Vavoula, 2007), CONTSENS (Cook, 2010a))

Approaches to mlearning vary from a focus upon content delivery (McKinney, Dyck, & Luber, 2009), SMS (Mellow, 2005), polling (Dyson, Litchfield, Lawrence, Raban, & Leijdekkers, 2009), and location awareness (Educause Learning Initiative, 2009a; Pachler, et al., 2010), to facilitating student generated content sharing (Sharples, et al., 2007), and augmented reality (Priestnall, Brown, Sharples, & Polmear, 2009; Sharples, 2009). In their review of one hundred and two innovative mobile learning projects published between 2002 and 2007, Frohberg et al. (2009) found that only five percent of these projects focused upon social learning, less than four percent required higher level thinking, with eighty nine percentage targeting novice learners, and ten percent facilitated user-generated content. Many mlearning studies focus upon content delivery for small screen devices (Stead & Colley, 2008) and the personal digital assistant capabilities of mobile devices (Corlett, Sharples, Bull, & Chan, 2005) rather than leveraging the potential of mobile devices for collaborative learning as recommended by Hoppe, Joiner, Milrad and Sharples (2003):

> Content delivery to mobile devices may well have a useful place in m-learning, however, there is an imperative to move from a view of e- and m-learning as solely delivery mechanisms for content… Handheld devices are emerging as one of the most promising technologies for supporting learning and particularly collaborative learning scenarios. (Hoppe, et al., 2003, p. 1)

The researcher has managed and implemented almost thirty mlearning projects between 2006 and 2011 using a participatory action research methodology (Swantz, 2008; Wadsworth, 1998) with each successive mlearning project forming a research cycle within a longitudinal research project. The focus of these mlearning projects has been on exploring the potential of mlearning as a catalyst for transforming pedagogy from instructivist lecturer-directed pedagogy to social constructivist pedagogy enabling student-generated content and student-generated contexts (heutagogy). The mlearning projects encompassed nine different tertiary courses, effectively forming nine case studies involving several research cycles spanning from one to four years of implementation and refinement, utilizing a range of wireless mobile devices (WMDs), and involved a total of 690 participants. The learning contexts included:

- Bachelor of Product Design (2006 using Palm Lifedrive, 2008 using Nokia N80, N95, and Apple iPhone 3G, 2009 using Nokia XM5800, N95, N97, 2010 using student-owned laptops and cameraphones, and Nokia N97)
- Diploma of Landscape Design (2006 Using Palm TX, 2007 using Nokia N80, 2008 using Sonyericsson P1i, 2009 using Dell mini9 netbook, 2010 using Nokia XM5800)
- Diploma of Contemporary Music (2008, 2009 using iPod Touch, iPhone 3G, 2010 using Apple iPad)
- Bachelor of Architecture (2009, using Nokia XM5800 and Dell Mini9 netbook, 2010 using Android HTC Desire smartphones and Apple iPads)
- Bachelor of Performing and Screen Arts (2009 using Dell Mini9 netbook and Nokia XM5800, 2010 using Dell Mini9 netbook, Nokia XM5800, and Nokia N97)
- Bachelor of Business (2010 using Apple iPad)
- Bachelor of Computing (2010 using Apple iPhone)
- Bachelor of Graphic Design (2010 using Nokia XM5800 smartphone)
- Bachelor of Civil Engineering (2010 using Apple iPad)

Figure 3 provides an outline of the growth and scope of the researcher’s mlearning projects 2006 to 2011. The generic term Wireless Mobile Devices (WMDs) is used to cover the variety of smartphones, netbooks, and touch-screen devices used throughout these projects.

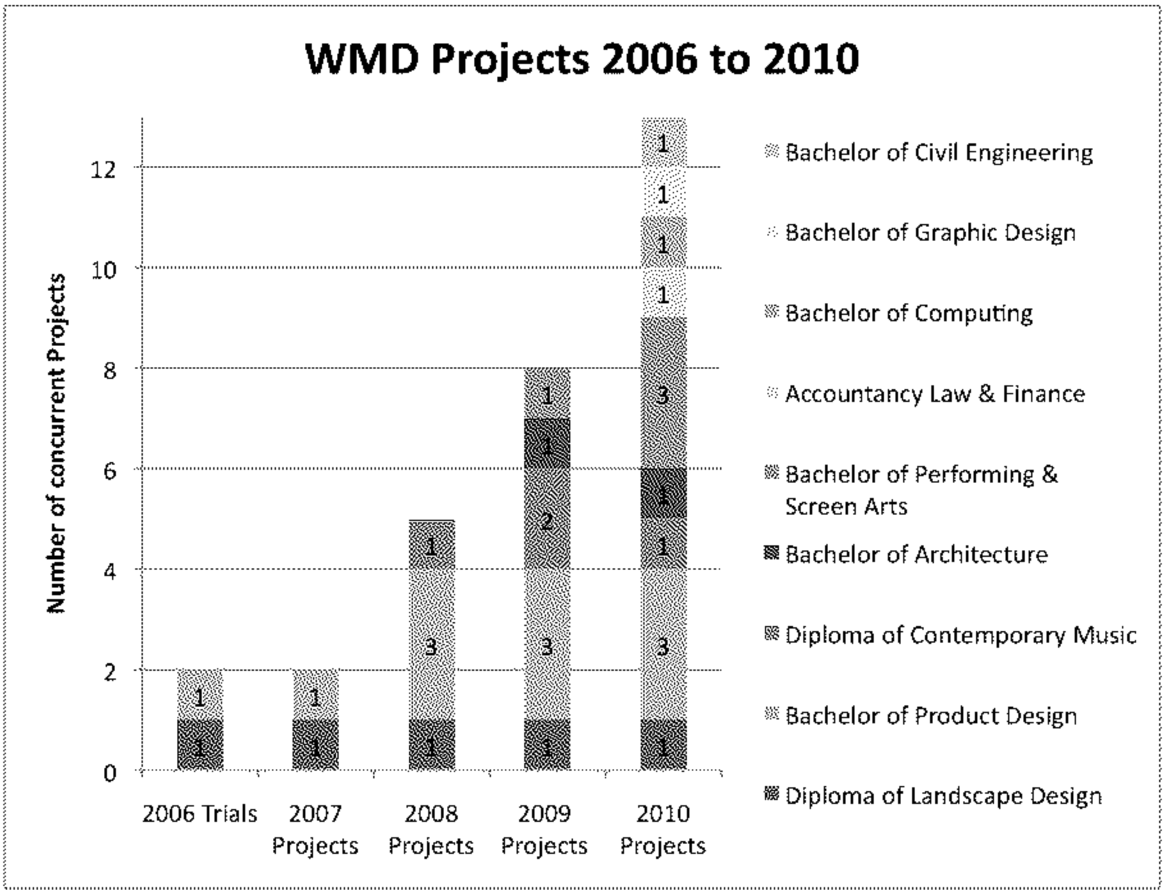

Figure 3: Number of mlearning projects 2006 to 2010.

Discussion: How

A significant body of peer-reviewed collaborative research between the researcher and a variety of lecturers from different course contexts has evidenced the impact upon lecturers' pedagogy and the depth of practice-based reflection that these projects have generated. For example: (Cochrane & Bateman, 2010; Cochrane, Bateman, Cliffin, et al., 2009; Cochrane, Bateman, & Flitta, 2009; Cochrane & Flitta, 2011; Cochrane, Narayan, & Oldfield, 2011; Cochrane & Rhodes, 2011; Flitta, Cochrane, & Bateman, 2009). This section discusses five examples of mLearning in different learning contexts, selected from the researcher's 2009 to 2011 mlearning action research cycles. The five examples illustrate the potential of the unique affordances of mlearning to enable pedagogical transformation that focuses upon student-generated content and student-generated contexts. Pre-project surveys of participating students have indicated that the majority of students were consumers of web 2.0 content rather than producers. In particular, the pre-project surveys revealed that prior to their involvement in the mlearning projects, the uptake of mobile tools such as Twitter was relatively low among these students.

We have found that for the majority of our students the engagement with these mobile web 2.0 tools for student-generated content and student-generated contexts is a new experience and requires significant scaffolding. This scaffolding was provided by embedding each mlearning project within a community of practice including the students, their lecturer, and the researcher as the "technology steward" (Wenger, White, & Smith, 2009) guiding the integration of these tools within each unique learning context.

QR Codes

Mobile codes are two-dimension codes similar to bar codes found on product information labels. There are a variety of mobile code formats, with the most popular being QR Codes (Quick Response Codes). A QR Code is decoded by an application on a cameraphone that uses the phones built-in camera to scan the code. QR Code decoding applications are available for a wide range of cameraphones, with most being free to download and install. QR Codes can represent a variety of information, including: URL's, a paragraph of text, an SMS message, a business card, or a geolocation (longitude and latitude information for an object). QR Codes can be simply generated using a variety of freely accessible web forms, such as: http://mobilecodes.nokia.com, http://www.splashurl.net, http://zxing.appspot.com/generator/. These codes can then be uploaded to websites, printed, or projected for decoding in a variety of contexts. The potential for the educational use of QR Codes resides in their ability to augment traditional information sources.

> QR codes link the physical world with the virtual by providing on-the-spot access to descriptive language and online resources for objects and locations. In this way, the codes support experiential learning, bringing scholarship out of the classroom and into physical experience. (Educause Learning Initiative, 2009c, p. 2)

During 2009, third year Product Design students featured the QR Code capabilities of their smartphones as a theme in their final graduation show. Students used QR Codes to annotate their presentations, and created individual business cards augmented with QR Codes that could be scanned creating an automatic address book contact on visitors' cameraphones. Each student created a QR Code that linked their final design project presentation to a Wordpress blog site providing visitors with more information on the students and their projects. The students demonstrated how to use the QR Codes on their smartphones to the Grad show visitors, decoding the QRCode URLs and showing the mobile version of their showcase blogs. Figure 4 illustrates the use of QR Codes within the third year Grad Show advertising flyer. The QR Code is the URL of the students' combined Wordpress blog with a summary of all of their projects. QR Codes were also used to theme the grad show booklet that was printed and made available to the show visitors.

Figure 4: 2009 Third year Product Design student Grad Show invitation flyer.

Augmented Reality

Augmented reality applications utilize a smartphone's camera to view the real world with overlaid augmenting digital information. This represents a significant unique affordance of smartphones, as described by Cook

(2010b). “The nature of learning is being augmented and accelerated by new digital tools and media, particularly by mobile devices and the networks and structures to which they connect people” (Cook, 2010b, p. 1). “An important affordance of mobile technology is that of digital augmentation, whereby contextual data is added to objects to enable a deeper understanding of them and richer meaning making” (Cook, 2010b, p. 2). However rather than being used as an enhancement for student-generated projects, the majority of smartphone based augmented reality applications have focused upon an enhanced teacher-directed content delivery paradigm. For example, Cook’s (2010a) mlearning research projects focused upon augmenting the learners experience in the field, and in reflection he asks “How do we get beyond good and useful exemplars?” (Cook, 2009b, p. 35). He proposed that to get wide scale practitioner and institutional up-take requires an institutional cultural change. Several criticisms can be leveled at Cook’s ‘exemplars’: the projects do not demonstrate a focus upon student-generated content or contexts as they are pre-defined, there is no long-term change in student learning paradigms as these are short day-long projects with no longitudinal scaffolding for students to personally appropriate the use of the mobile tools beyond the project, the students involved were self-motivated learners and involve small numbers minimizing transferability, and there is a high technical requirement for these projects involving the development of project-specific and intricate augmented reality multimedia.

To minimise the technical expertise required for mlearning implementation and maximise transferability, while explicitly using a social constructivist pedagogical foundation, the researcher decided to focus upon the potential of mobile web 2.0. Mobile web 2.0 enables learner-generated content and learner-generated contexts.

Using mobile web 2.0 developing Augmented Reality applications has become a relatively simple process that anyone with a compatible smartphone can now achieve (Butchart, 2011) by creating user-generated content for mobile web 2.0 augmented reality browsers such as Wikitude, Layar, and Junaio. These tools enable bridging learning contexts by supporting learner-generated contexts using the built-in camera, GPS and compass to overlay the physical environment with student created POIs (points of interest) and location-based data. However the uptake of these tools within educational settings is still in very early stages.

> Uptake of smartphone based AR in education has been very modest so far. We have not found any examples of channels being created in existing AR browsers such as Layar and Junaio that are specifically geared towards learning and teaching. Most likely, this is due to the immaturity of both the AR browsers and tools for publishing content rather than aversion to the idea of augmented reality itself. (Butchart, 2011, p. 38)

The educational use of student-generated augmented reality content is illustrated by the 2010 eCV elective project within the Bachelor of Architecture course at Unitec. The 2010 eCV10 Architecture mlearning project investigated bridging student generated ePortfolios and digital storytelling facilitated by the latest generation of mobile devices, allowing the capture and organization of this content to be contextual and based in authentic environments beyond the classroom. Lecturers and students were provided with an Android smartphone (HTC Desire) and an Apple iPad for the duration of the semester-long project. Students worked in four negotiated teams, initially proposing a group eportfolio project that utilized the unique affordances of the mobile tools. The Archifail team project captured images and mobile videos highlighting and critiquing poor Architectural design around Auckland City. The team created a Wordpress portfolio (http://archifail.wordpress.com/), and also created a layer for the Wikitude augmented reality mobile browser (http://prezi.com/byy1rnidvw-i/archifail/). This Wikitude layer included geographically tagged locations of failed Architectural design, supplemented with images and a short critique by the students of the design failures. Anyone with a compatible smartphone could then download the Archifail layer to Wikitude and use the smartphone’s built-in camera coupled with its GPS and compass to locate these points of interest overlaid as digital information on the real-world viewed through the smartphone’s camera. The students then created a tutorial explaining the steps involved in creating a Wikitude AR layer for the other eCV student teams (http://dave16288.blogspot.com/2010/11/wikitude-tutorial.html).

Twitter

Twitter has grown into one of the most popular microblogging platforms, with a user-base growing 1382 percent in 2008 (McGiboney, 2009) and over 1500 percent during 2009. Twitter can be used either asynchronously or synchronously to enhance communication and collaboration. As a primarily text-based tool Twitter is capable of working from any cellphone using SMS, but can be enhanced using smartphones with GPS, photo and video integration within a variety of Twitter applications, for example: the official Twitter mobile app, Twitterriffic, Tweetdeck, and the imminent 'deep integration' of Twitter into iOS5 for the iPod Touch, iPhone, and iPad (http://www.apple.com/ios/ios5/features.html#twitter). Twitter is a useful tool for enabling communication and collaboration (Educause Learning Initiative, 2009b), developing and maintaining geographically disperse communities of practice, and has become deeply integrated into many of the most popular web 2.0 blog hosts and media sharing sites (for example: Wordpress, Typepad, YouTube, Qik, Flickr, Ning). This integration with a wide variety of web 2.0 tools allows Twitter to become the social network linking users' eportfolios built from a collation of web 2.0 tools, allowing a flexible personal learning environment to be customized by the end-user. Thus in our mlearning projects that focus upon collaboration and student-generated eportfolios Twitter has become the primary communication and collaboration hub.

Buchem and Hamelmann (2010) discuss the potential for using Twitter for creating communities for professional development. Buchem (2011) also emphasizes the serendipitous nature of the use of Twitter in creating opportunities for unplanned collaboration and discovery. Our experience supports Buchem's propositions, as several of our mlearning projects that have utilized the affordances of Twitter have led to serendipitous (unplanned but fortuitous) outcomes (Cochrane, 2010). Twitter has been used in a variety of contexts within our mlearning projects, including: enhancing face-to-face discussions and brainstorms with live Twitter searches projected for the participants to view, beyond class discussions, and as a core asynchronous communication tool between geographically disperse student teams across international time-zones.

Mobile Movie Making and Video Streaming

Almost any cameraphone can record short video clips that can then be uploaded to web-based video hosts for sharing and distribution such as YouTube and Vimeo. Smartphones feature basic video editing tools directly on the smartphone, enabling titling, editing of multiple video clips and clip transitions – thus allowing a fully mobile video to be shot, edited, and shared from a mobile device. There are also several mobile live video-streaming applications and services for smartphones, including: Qik, Ustream, and Bambuser. The size, portability, ubiquitous connectivity, and long battery-life of cameraphones enable capturing of ideas and sharing of experiences in virtually any context, enabling student-generated content within student-generated contexts.

Mobile Film festivals have become popular in Europe (BBC, 2009; Mobigardens, 2010; Mobilizedtv, 2011) and Australia (Ratnanesan, 2010). This provided an opportunity to leverage some of the international expertise in this emerging field, and was particularly relevant for several mlearning projects within Film and Television elective courses between 2009-2011. The 2011 Film and television course elective "entertainment lab for the very small screen" (ELVSS11) explored team-based student-generated mobisodes (short mobile video episodes) using iPhones to capture video in unique ways, and iPad1's to edit and upload the mobisodes to YouTube. The five team mobisodes and student reflections on the project are available on the YouTube channel: http://www.youtube.com/user/ELVSS11#g/u. Using the iPhones students explored and made examples of filming techniques and positions that were unachievable via traditional film making using standard production-level digital cameras and crews. They also critiqued the advantages and limitations of the small screen format. This project not only explored an innovative use of mobile technology, but also enabled the course lecturer to reinvent the course's underlying pedagogy. The course was redesigned from a set of content-delivery lectures, to developing student-negotiated and student-generated team projects that were supported by the input of a range of mobile learning experts, both locally and internationally. Each face-to-face class session involved an overview of an aspect of mobile video production, and was followed by student-led discussions (enhanced with a live Twitter feed) around the development of their mobisode projects. Class notes and outcomes were negotiated with the students and made available on Google Docs. Remote guest lecturers from Wellington (NZ) and the UK (Salford University) were brought into the class via live Skype feeds, with interaction and questions enabled via both the live and asynchronous use of Twitter.

Situated Learning

The mobility and ubiquitous connectivity of smartphones allows them to be used within a wide variety of contexts – enabling student-generated learning contexts beyond the classroom, and enables lecturers to design learning experiences that bridge multiple contexts. Laurillard argues that "M-learning, being the digital support of adaptive, investigative, communicative, collaborative, and productive learning activities in remote locations, proposes a wide variety of environments in which the teacher can operate" (Laurillard, 2007, p. 172). Similarly, Herrington et al. (2009) argue that mlearning enables the use of new pedagogies that support authentic contexts in learning. This is illustrated by the development of the integration of mlearning linking theory and practice on site within the building technology course at Unitec.

During 2010 a building technology lecturer participated in the inaugural 2010 class of the Social Learning Technologies course developed and facilitated by the author (Cochrane & Narayan, 2011). The course was modeled on an intentional community of practice (Langelier, 2005), with the participants investigating the potential impact of the integration of mobile web 2.0 tools in education, based upon social learning theories. The participants were required to apply what they learnt and experienced to their own teaching practice. As a result one lecturer conceptualized and designed (using Google Sketchup) a portable 'eShed' or 'smartshed' that could be transported to the building sites where his students engaged in practical work experience, creating a direct link between theory and practice without the separation of theory lessons taking place in the context of a classroom off the building site. The eShed became a reification of the lecturer's reconceptualisation of teaching and learning based upon social constructivism and Laurillard's (2001, 2007) conversational framework. The concept was enhanced by leveraging the affordances of student-owned smartphones via the utilization of QR Codes for annotating building site components with rich media including YouTube video construction examples and Google sketchup building plan detail, and also the embedding of student blogs as live journals of their learning experiences on and off the building site including student captured photos and videos via their smartphones. Live streaming of mobile video via services such as Qik were also designed to allow participation by remote students, or live demonstrations across the building site streamed directly to the eShed smartboard, creating a virtual community of practice that links the physical community of practice. The eShed was given faculty approval in 2011 and constructed mid 2011. The final version of the eShed includes: an interactive smartboard, a video projector, internet connected PC, a wifi access point providing internet access across the entire building site, and storage of class sets of mobile devices such as iPod Touchs. The eShed will also allow students to view, interact and modify building plans on site via Google Sketchup, and present and discuss their course eportfolios to their lecturers and fellow students on site. Thus the eShed will become a focus for linking theory and practice, and enabling on site discussion, reflection, action, and 're-action'. An online presentation of the eShed development and sample video footage is available at http://prezi.com/ymotphudnegm/real-world-learning/.

Conclusion

The paper makes a case for the impact of mlearning to enable student-generated content and student-generated contexts in tertiary education. Five practical examples of the application of mlearning are drawn from the researcher's experience of implementing and evaluating over twenty-five mlearning projects between 2006 and 2011. Thus the paper illustrates what can be achieved by the creative and innovative planned pedagogical appropriation of the devices that our students are most likely to own – a cameraphone or similar mobile device.

Nicola Building Virtual Tour; Considering simulation in the equity of experience concept

Meg Colasante
College of Science, Engineering and Health
RMIT University

Examining equity of learner experiences across delivery modes is a contemporary issue, particularly in comparing onshore and offshore or local and distance experiences. This paper begins the journey of reviewing equivalence of learning experience for local and distance students in a vocational course in a Property Services learning program, just as this case joins a larger multiple-case study examining equivalence. It focuses on the potential of a simulation in providing equivalent ‘practical’ experience of conducting a building inspection. A simulation designed to help achieve this, the Nicola Building Virtual Tour, was trialed in a small cohort in the Property Services program, and a survey harnessing learner opinion of this tool received largely positive feedback, but also provide some guidance in how to proceed.

Keywords: Simulation; virtual tour; equivalence; property services; vocational tertiary sector.

Introduction

Equity of learner experience in onshore and offshore delivery modes is an issue of focus in several universities in Australia, particularly since the 2007 approval by the Ministerial Council on Education, Employment, Training and Youth Affairs for a national protocol directly related to this (MCEETYA, Oct 2007: protocol 14, p.2, in Palaskas et al 2010). At RMIT University, Melbourne, there has been intensive work on an evolving project focusing on equivalence between on and offshore student experiences (i.e.: local students compared to students studying from outside Australia) in like learning courses (subjects). This work has resulted in ‘a model for achieving equivalence and comparability in higher education courses offered ‘transnationally’ in the College of Business at RMIT (Gopal et al., 2010). The project has since extended in two project directions; the first into a university-wide implementation planning phase, and the second, a focus on how educational technologies can help achieve equivalence and comparability in learning experiences. The latter, in draft as ‘Harmonisation of onshore and offshore teaching supported by enterprise educational technology’ (Botterill, 2011), is under review by learning and teaching staff against the contexts of sample courses in both higher education and vocational (TAFE/college) tertiary sectors, using multiple-case study methodology. This concise paper highlights the commencement of reviewing one such targeted vocational case for review of equity of experience with supporting educational technology, in the Property Services learning program. In particular, it focuses on the use of a virtual tour designed to better support off-campus or distance learning by providing ‘access’ to a facility to enable virtual building inspection practice.

The Nicola Building Virtual Tour was integrated into the Property Services program in 2010 and evaluated by way of surveying students post integration. Focusing on this tool was in recognition that while content-rich learning might readily transfer via enterprise educational technology options (e.g., lectures or tutorials via Lectopia or Elluminate; see Botterill, 2011), practical and applied learning experiences require additional consideration. Online interactive activities are well established for learners to apply concepts and skills; helping to engage, motivate and enable practice to reinforce learning (e.g., JISC, 2004). However, it remains important to evaluate the quality of learning offered in growing online and global education markets as "High performance standards, commitments to practice, and ethical conduct legitimize virtual curricula and the environments in which learning takes place" (Carrier, 2010:28). The survey data comprised largely positive responses to the virtual tour as an activity and an alternative to physical building inspection. The minority negative responses were generally further illustrated by free form, qualitative survey responses, which were useful for tool improvement and for consideration of implementation issues across differing delivery modes.

The 'Property Services' case context

The Certificate IV in Property Services is delivered in several program offerings in the vocational sector of RMIT, to cater for a range of specific learner cohorts locally and interstate and is currently under analysis for offshore/international delivery. Each Property Services offering presents in a different blended learning mode to suit the learner cohort, including blends of in-class, workplace and online/distance learning, where in-class can be on-campus locally scheduled classes or interstate 'fly-in expert' intensive workshops. The broad program structure is made up of a mix of core plus cohort appropriate Units of Competency (training curricula/modules), which are 'chunked' together into several learning 'themes' for meaningful delivery. Several of these units require access to physical properties such as residential, commercial or public facilities. For example, the unit 'Plan and coordinate property and facility inspection' falls under the learning theme of 'Maintenance and Service in the Property Industry'. This theme is currently undergoing learning re-design and development, while the 'inspection' unit has been selected for review against principles of equivalence or 'harmonisation' across the various delivery cohorts.

The 'Harmonisation' or equivalence project

The 'harmonisation' project (Botteril, 2011) acknowledges that educational technologies are not used to the same advantage in offshore RMIT teaching courses compared to onshore. It recommends an increase in technology use in the support of elements of equivalence and comparability (Palaskas and Gopal, 2011, in Botterill, 2011). The project promotes the institute's current range of educational technologies but also includes the open-ended technology of 'eSimulations', or "virtual simulations … [that] allow students to demonstrate theory in practice in non-threatening or risk-free situations while ensuring active learning experiences" (Botterill, 2011:22), highlighting usefulness in situations of limited access to resources.

Nicola Building Virtual Tour / simulation

Traditionally, building inspections are conducted during scheduled on-campus (local) Property Services classes utilising an ageing building, under the supervision of teaching staff with follow-up debrief activities. For the Nicola Building tool, a similarly aged building was specially photographed for 'stitching' together into a virtual tour for online learning access. Additionally, the images were graphically altered to provide more interest areas for inspection (predominantly faults) under the guidance of a subject matter expert. Support resources such as an inspection report template and a how-to guide were designed and developed. Learner access to the tool and resources were then enabled via the institute's learning management system (Blackboard™).

Figure 1: Screen capture of Nicola Building Virtual Tour

The Nicola Building simulation is a web-based Virtual tour not unlike what property services personnel employed within the real estate industry are familiar with, with exceptions mainly related to purpose. An example of divergence is that most property tours aim to highlight advantages while a building inspection for learner critique needs a more realistic view; they need access to both faults and advantages to enable a realistic facility report to be produced. The Nicola Building comprises two floors, and allows the learner to navigate their own way through the building moving from area to area as they choose. Depending on the intended learning outcomes for each relevant course activity, the teacher sets instructions utilising the tour, predominantly for what type of inspection report is required but also for other learning purposes such as safety and risk analysis. The learning goal in the trial was to produce an inspection report detailing the current condition of a facility, emulating the standard required in the industry.

The Nicola Building Virtual Tour was trialed by the traineeship cohort of Property Services (Operations) students. The traineeship students attended weekly classes on-campus and benefitted from concurrent training in their various property services work environments. The students were mature-aged and had a range of workplace roles and industry experiences. Fifteen students out of a class of 24 completed a paper-based survey after using the virtual tour in their classroom activities. The survey comprised both quantitative and qualitative questions, including 11 five-point Likert scale questions seeking responses of ‘Strongly agree’ through to ‘Strongly disagree’, followed by six open-ended questions. The first open question asked for detail related to the responses given to the previous quantitative responses, and others sought to draw out both negative and positive aspects of learning with the simulation.

Findings

Generally, the students in the trial positively received the Nicola Building Virtual Tour, as reflected in Figure 2. An additional question posed in the negative: ‘I was very unsatisfied using Virtual Tour’, received only two responses out of 15 that indicated they were unsatisfied with the tool. Another question set, asking for opinions of the tool as a regular part of the course for future students, received predominantly positive responses.

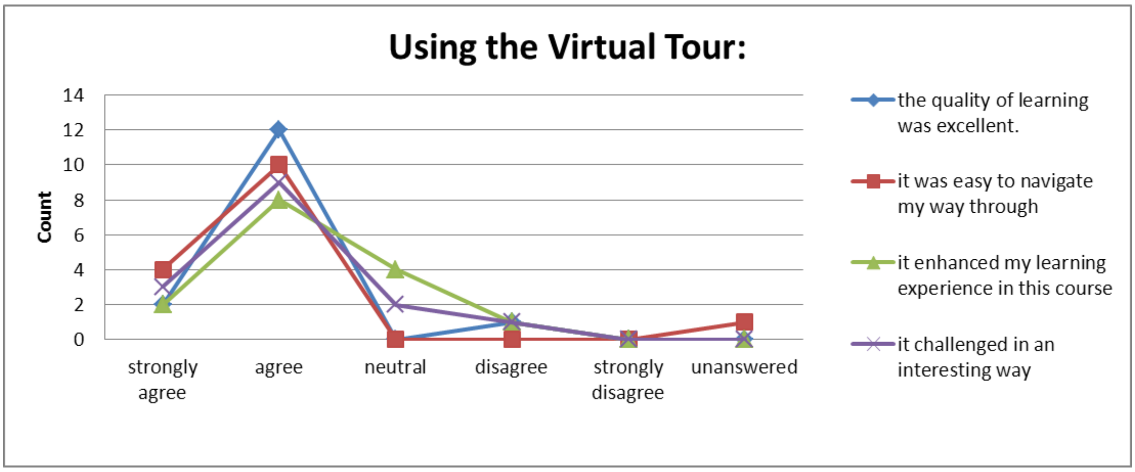

Figure 2: Learner perceptions of general learning value of the Virtual tour

However, the results were more mixed in key questions seeking to determine if the tour was a good replacement for a physical/actual building tour. Responses (see Figure 3) raised the question of why were up to 2 in 5 students either neutral or negative in that the tool was excellent for inspecting a facility? Some explanation of this was found in the qualitative responses discussed below.

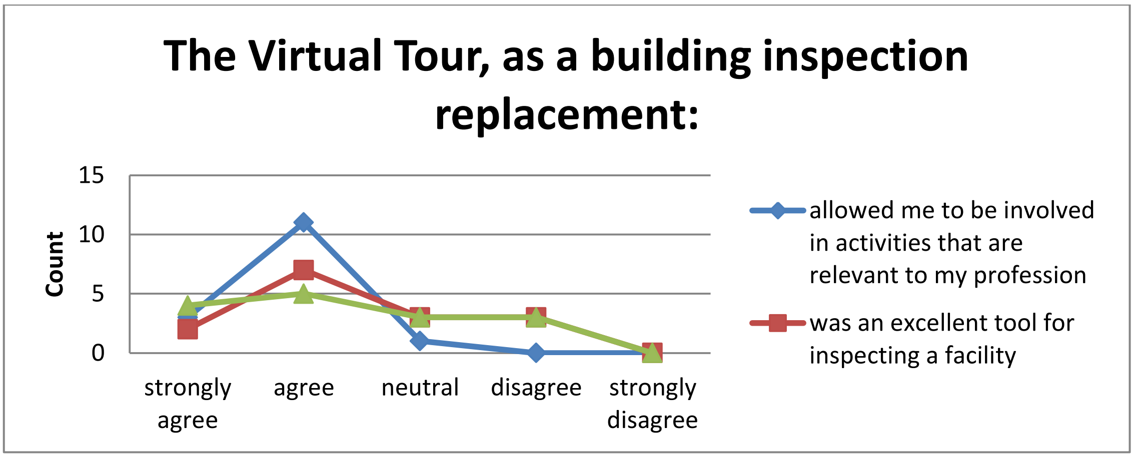

Figure 3: Learner perceptions of the Virtual tour for building inspection

The qualitative open-ended responses were themed into five main issues: technical problems, learning and teaching, and instructions/support materials, with all remaining in either positive or negative issues (not already coded into other themes). A number of issues raised were simply dealt with by tool and/or accompanying resource improvement, while others were illustrative for the focus of this paper.

Positive overall views were the most common feedback items, and included responses such as: "I thought it was excellent. A great learning tool & experience"; "Easy to use"; "Easy and quick access to facility inspection"; "Flexible & Freedom – not restricted to access"; "Alternate method for a building inspection remotely"; "Ease and the fact that it was quicker to have a look and take notes as opposed to the normal running around"; "Refer back to it if something is missed"; "The visual aide instead of referring to powerpoints or documents only".

The negative issues related primarily (and importantly to this paper) to a virtual tour not being as effective as a real tour, for example, "Not able to look in every nook & crannie [sic.] (detail)"; "I think you pick up more in the actual tour"; "Easier to detect faults when looking in real life". This seems to indicate that while the virtual inspection is useful in learning, it is likely to continue to be appropriate in combination with real-life/physical building inspections, regardless of the delivery cohort (on/offshore, etc.). That is, at an appropriate point in the course, a real inspection could be available via teacher-industry cooperation to allow the full benefit of the simulation to be realised. The tour could therefore provide preparation and/or repeated practice.

General learning and teaching issues were highlighted. Three students noted the need for some content direction before the tour, particularly if they hadn't been exposed to inspection tours before and needed orientation. For example, "for people who have not completed inspections before it is difficult to know what to comment on"; "I think there would be greater value in talking about different types of inspections. Eg. OHS. Property condition – life cycles & maintenance"; "Enable feedback on area's to inspect if not use[d] to this in role".

Discussion

Issues of equivalence and comparability of simulated practical learning versus alternate methods of learning are offered in the literature. For example, in a study involving learning electrical wiring by computer simulation (Liu and Su, 2011), it was found that students who used the simulations performed better than those accessing only lectures and demonstrations, and, compared to laboratories, simulations allow more time on task compared to set-up for actual experiments. The study also provided warnings, including that simulations may not provide the same level of irregularities as found in real-life scenarios, and that hints and supports should be available virtually instead of waiting for teacher feedback. This would apply to the Nicola Building Virtual Tour, in that the students who were perturbed by not having access to the same level of detail as an actual tour could be better supported by management of expectations of what can be achieved and offered feedback by direct teacher responses and/or access to a worked example to compare with own work (e.g., sample inspection report).

The learning and teaching issue of prior knowledge raised in the findings remains an important one for future issues of on and offshore or local and distance equivalence. Simply assuming adequate prior knowledge for such simulations is no substitute for basic learner needs analyses. In noting problems in learning from early computer-based simulations, Stead (1990) cited work by cognitive psychologist Ausubel (1978) to acknowledge simulations were of no value "to those with no prior knowledge of the topic … [as they] would be unable to interpret information from the simulation [as] meaningful" (p.107). Findings from the Nicola Building trial would indicate this is still the case. Other caution is found in Stead's work in relation to equivalence in learning experience, highlighting the need to embed the simulation in a complete learning activity, including the need for "time … to permit reflection and discussion" (p.116). Thus providing a reminder that simulations shouldn't be simply given to offshore/distance cohorts without adequate learning and teaching support structures in place.

Evaluation of alternative feedback mechanisms on student engagement with assessment feedback

Professor Stephen Colbran
University of New England

This study examined students' perceptions of the usefulness of assessment feedback provided by ReMarksPDF and provides a summary of positive and negative aspects of different types of feedback annotations. Students randomly received one of 7 different combinations of feedback. 74.9% of students found ReMarksPDF feedback better than that they have received in the past and 73.2% of students agreed or strongly agreed that other units should adopt the ReMarksPDF system. Students found the mark tally table, assessment rubric, spider chart, spider chart (with average), colour coding and smileys to be significantly valuable feedback in that order of preference. Females gave higher ratings than males on all feedback types, except spider charts, which were equally highly rated by males. Respondents indicated that ReMarksPDF feedback was easy to read and understand and that it was beneficial to have comments appear in a side column note.

Keywords: Assessment feedback, Electronic marking, ReMarksPDF, Electronic Assessment.

Introduction

Assessment drives student learning and effort (Kendle & Northcote, 2000) and in turn influences the direction and quality of student learning (Maclellan, 2004). Numerous literature reviews indicate that feedback is critical to improving the standard of student work and learning (Black & William1998a; Hattie 1999; Heinrich 2006, Huber & Mowbray 2011) and that both formative and summative assessment directly affect student engagement. The structure of assessment designs often includes formative feedback. Feedback, at its best is individual in focus, outlining strengths and weaknesses and avenues for self-improvement (Linn & Miller, 2005; Heinrich 2006). Electronic feedback management systems such as ReMarksPDF offer opportunities for improvement in assessment practice and outcomes for students, including:

4. E-submission, allocation, marking, moderation and assessment return via a learning management system
5. Extensive annotation and commentary features, including rubrics, stamps, electronic dashboards and charts
6. Links to electronic portfolios classified by learning outcomes or graduate attributes
7. Quality management including consistency, reporting, and self-reflection

The purpose of this research was to determine students' perceptions of the usefulness of alternative forms of feedback provided using ReMarksPDF, an advanced PDF annotator for Windows, Mac and Linux, developed with the assistance of the ALTC – see www.remarkspdf.com. ReMarksPDF is an enterprise system (Blackboard 9.1 and Moodle 2.1) enabling e-submission, allocation to markers, marking (text, audio and video comments, colour coding, smart charts, stamps etc), extensive moderation, and return of assessment to students and marks to gradebook.

Figure 1 depicts the three main types of feedback examined in this study - Spider Chart, Spider Chart (with average) and Smiley (Highly negative, Negative, Neutral, Positive, Highly positive). Refer Figure 1.

Figure 1: Spider chart, Spider chart (with average), Smiley scale

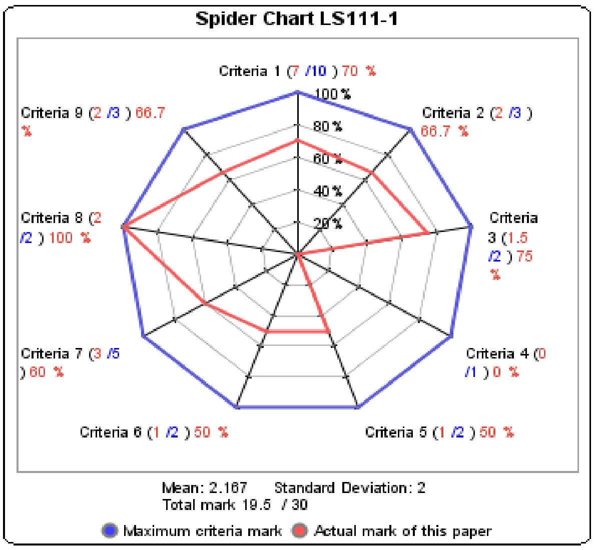
Method

A total of 154 (61 male, 93 female) Law students out of a single cohort of 210 students enrolled in LS111 Civil Procedure during Semester 2, 2010 at UNE voluntarily completed a survey on feedback received in relation to a draft Statement of Claim submitted in satisfaction of 30% of their grade. Each of three markers was randomly assigned 7 groups of 10 students who had randomly received one of seven distinct types of assessment feedback. Each group had a maximum of 30 participants. Refer Table 1. All assessment and requests for participation in the survey were returned at the same time.

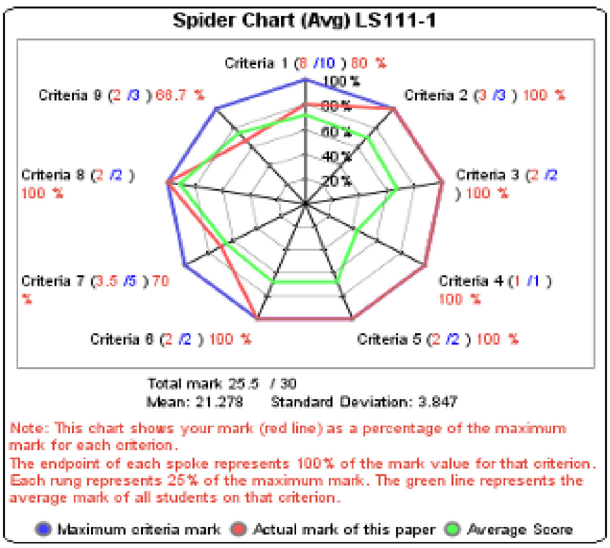
Table 1: Groups, Feedback type and Response rate

Groups	Feedback type	Male	Female	n	Response rate
Group 1	Spider chart	9	16	25	83.3%
Group 2	Spider chart (with average)	11	8	19	63.3%
Group 3	Smiley	9	12	21	70.0%
Group 4	Spider chart + Spider chart (with average)	8	13	21	70.0%
Group 5	Spider chart + Smiley	12	12	24	80.0%
Group 6	Spider chart (with average) + Smiley	6	13	19	63.3%
Group 7	Spider chart + Spider chart (with average) + Smiley	6	19	25	83.3%

All students were provided with additional feedback consisting of an assessment rubric, colour coding according to a colour key, a marking tally, and pre-prepared comments based on a marking guide. Marking was done electronically using ReMarksPDF <www.remarkspdf.com>. Figure 2 shows the ReMarksPDF interface in Mac OS X Lion together with the Moderation panel showing



er



the distribution of grades. An actual student paper is open, on the right, showing their Smiley rating, Average Spider Chart indicating achievement on each criterion, Mark Tally Table, Colour coding and Auto Text comments. A survey instrument, ethics approval HE10/165 was prepared and administered on-line using Qualtrics <www.qualitics.com> - see http://remarkspdf.com/research. The survey instrument was designed to elicit student responses to different types and combinations of annotations.

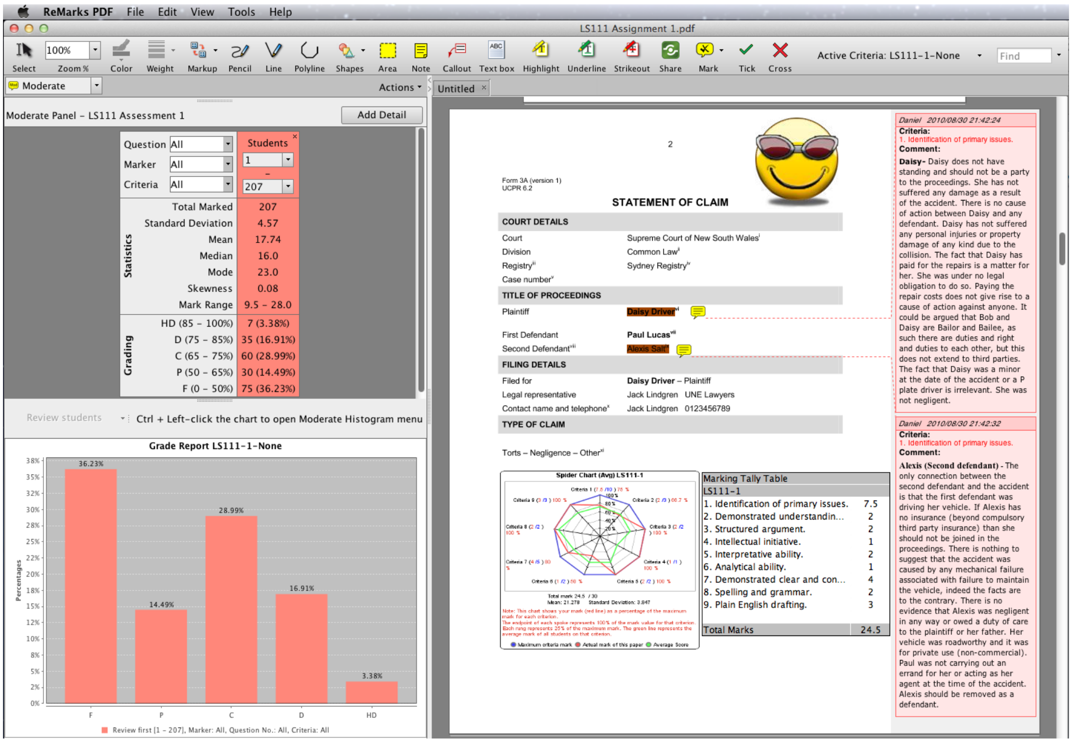


Figure 2: ReMarksPDF interface

Results

Students were asked to rate the overall value to them of the types of feedback annotations received. The results appear in Figure 3 and were significant at the 5% level (p = 0.000). A one-way ANOVA and post-hoc multiple comparisons did not reveal any association with equivalent full-time year, age or group.

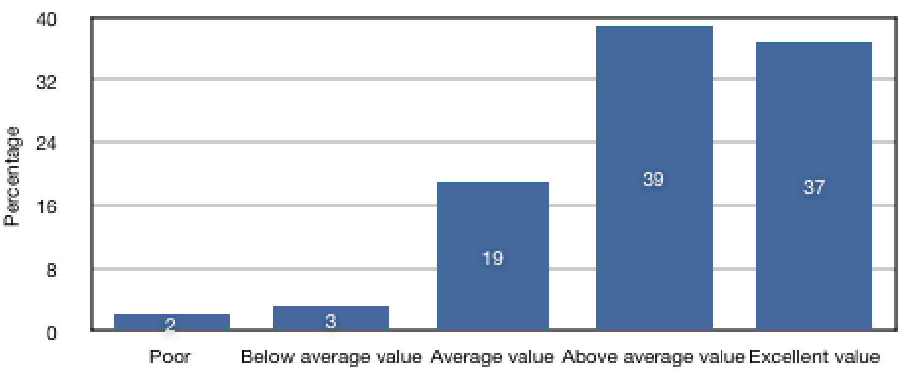

Figure 3: Overall value of Feedback

A t-test indicated females rated overall value more highly than males (p = 0.044). Neither mode nor attendance had any significant effect on the results.

Students were asked to rate the different types of annotations they received on a 5-point LIKERT scale from 1 Useless, 3 Neutral, through 5 Very Useful. The mean ratings in order of usefulness appear in Table 2.

Table 2: Annotation data

Annotation	n	1	2	3	4	5	Mean	*t*	*p**
Mark Tally Table	140	2 (1.4%)	6 (4.3%)	14 (10%)	52 (37.1%)	66 (47.1%)	4.24	16.257	0.000
Assessment rubric	141	5 (3.5%)	4 (2.8%)	20 (14.2%)	67 (47.5%)	43 (30.5%)	3.94	11.458	0.000
Spider Chart	82	3 (3.6%)	7 (8.5%)	12 (14.6%)	32 (39%)	28 (34.1%)	3.91	-3.97	0.000
Spider Chart with average	78	5 (6.4%)	8 (10.3%)	9 (11.5%)	26 (33.3%)	30 (38.5%)	3.87	-5.77	0.000
Colour coding	139	3 (2.2%)	15 (10.8%)	27 (19.4%)	53 (38.1%)	41 (29.5%)	3.82	8.611	0.000
Smiley	82	11 (13.4%)	14 (17.1%)	16 (19.5%)	26 (31.7%)	15 (18.3%)	3.24	-8.07	0.000

6. Sig. (2 tailed) One-Sample *t* test based on a neutral response of 3. **n** indicates the responses from students in all groups who received that type of annotation.

An independent samples *t*-test confirmed females rated annotations more useful than males at the 5% level for all variables except for spider charts. There was no association between age and responses. Part-time students rated the assessment rubric as more useful than full-time students at the 5% level ($p = 0.035$). There were no significant differences for on-campus or off-campus students. A one-way ANOVA and post-hoc multiple comparisons did not reveal any association with equivalent full-time year or age.

Students were also asked a series of questions on what they thought of ReMarksPDF based on a 5-point LIKERT scale from 1=Strongly disagree, 3=Neutral, through 5=Strongly agree. The results are shown in Table 3.

Table 3: Question data

Question	n	1	2	3	4	5	Mean	*t*	*p**
The ReMarks system provides better feedback than I have experienced in the past.	139	6 (4.3%)	7 (5%)	22 (15.8%)	49 (35.3%)	55 (39.6%)	4.01	11.06	0.000
Other units should adopt the ReMarks feedback system.	138	10 (7.3%)	7 (5.1%)	20 (14.5%)	42 (30.4%)	59 (42.8%)	3.96	8.88	0.000
ReMarks feedback is easy to read.	137	10 (7.3%)	7 (5.1%)	20 (14.6%)	42 (30.7%)	58 (42.3%)	3.96	8.77	0.000
It is beneficial to be able to view side column comments.	137	4 (2.9%)	4 (2.9%)	14 (10.2%)	43 (31.4%)	72 (52.6%)	4.28	14.20	0.000
ReMarks feedback is easy to understand.	138	9 (6.5%)	5 (3.6%)	21 (15.2%)	51 (37%)	52 (37.7%)	3.96	9.97	0.000

⅄ Sig. (2 tailed) One-Sample *t* test based on a neutral response of 3.

An independent samples *t* test did not reveal any gender differences at the 5% level, except for question 1, where females more strongly agreed than males. Part-time students rated 'ReMarksPDF feedback is easy to understand' higher than full-time students at the 5% level ($p = 0.028$). Off-campus students significantly rated 'ReMarksPDF feedback is easy to read' and 'ReMarks feedback is easy to understand' higher than on-campus students at the 5% level ($p = 0.019$, $p = 0.016$). A one-way ANOVA and post-hoc multiple comparisons did not reveal any association with equivalent full-time year or age.

Open-ended questions sought to elicit positive and negative aspects of ReMarksPDF and the types of feedback annotations. Selected results appear in Table 4.

Table 4: Annotation positive and negative aspects

Positive	Negative
ReMarksPDF	
• Avoid unnecessary delay of results and it is legible. • Clear and able to read the comments. • Being online saves paper. • Combination of graphs and annotation makes it easy to understand the feedback. • Brilliant! I have never received more cohesive and detailed results in any other subject. • Legible feedback. It shows that a lot of thought was put into the correction. Like the breakdown of the marks to the different areas so we I can see where to improve for next time. Its shows that the assignment was marked objectively rather than subjectively.	• Was a bit overwhelmed at first. Being a new system, I wasn't expecting it. Once I took a deep breath and started reading, was not so overpowering. • I do not have any negatives about any of the marking system. • Sometimes difficult to match the comments to the relevant area of the paper. • Marker's comment windows sometimes difficult to get open so that comments can be read. • When you print the document the comments are not completely visible. • None that I can think of. • Use of colour scheme a bit over the top.
Spider Chart	
5. You can visibly see where each mark is sitting against the maximum so you can work on weaknesses and see the strengths. 6. It provides a snapshot of my strengths and weaknesses. 7. Easy to understand, easily read.	• Nil. excellent way of seeing how marks were awarded. • Confusing to interpret and understand. • I am old and staid. I just do not like being confronted with new things...like learning to work a computer before I could consider enrolling at unit.
Spider Chart (with Average)	
• Found this very useful and would like to see other subjects adopt the same approach. • Excellent system. • It provides a clear illustration of the students strengths and weaknesses. • It was quick and easy to understand. • Good to compare against the average. • Excellent idea, highly useful, makes it easy to understand my position in relation to my class.	• Can be complicated to read, but I do not think there is a negative aspect. • The overall average is shown, but the average for each criteria spoke is not shown. This would be helpful. • Need a second degree to understand it. Don’t get carried away with academics, this is the real world out here.
Smiley	
• Its a visual cue as to how your assignment went e.g. happy sad in the middle. • Something different. • I smiled then went on to read the comments regarding my paper.	• If you get a frown it could be discouraging. • A sad face lowers a student's self esteem. • Don't really think it is needed. • Too open to interpretation. • Perhaps a scale of what level of smileyness.

Comment

While there were both positive and negative aspects to ReMarksPDF and the three types of annotations discussed, ReMarksPDF was nevertheless a valuable new tool for assessment feedback. 74.9% of students found ReMarksPDF provided better feedback than they had received in the past. 73.2% encouraged wider adoption of the tool. Students found the mark tally table, assessment rubric, spider chart, spider chart (with average), colour coding and smileys to be significantly valuable feedback in that order of preference. It would appear that quantitative annotation and classification schemes were perceived by students as more useful than more subjective schemes involving colours and depictions of emotions.

Females gave higher ratings than males on all feedback types, except spider charts, which were equally highly rated by males. Software such as ReMarksPDF offers the opportunity to use types of feedback, which would be otherwise impractical to manually implement - such as dashboard charts and auto comments. It is anticipated that e-marking software will have a positive affect on student engagement and learning outcomes by enabling markers to efficiently provide detailed individual feedback, outlining strengths and weaknesses of the student assessment submission and avenues for self-improvement.

ReMarksPDF – Advanced Electronic Assessment Feedback

Professor Stephen Colbran
Law School
University of New England

Michael Garner
Learning & Teaching Systems, Division of Information Services
Griffith University

ReMarksPDF is an ALTC project designed to significantly improve electronic assessment workflows in the tertiary sector and enhance student engagement. The project is concerned with summarizing the literature on e-assessment workflows, the policy implications for universities, relevance to TEQSA data collection, moderation and monitoring learning standards, new mechanisms for moderation within marking teams, and integration with Learning Management Systems. ReMarksPDF provides tools for timely feedback, embedding feedback throughout student assessment submissions, criterion-referenced assessment, and advanced moderation and quality assurance tools. The poster summarises the current state of development of the project and the free availability of this advanced cross-platform marking software for Australian academics. Case studies of ReMarksPDF Blackboard integration at Griffith University and ReMarksPDF Moodle 2.0 integration will be displayed. Technologically based methods of providing quality student feedback is an essential paradigm shift towards faster, simpler and more efficient assessment workflows for the benefit of both academics and students.

Keywords: Electronic Feedback, Electronic marking, ReMarksPDF, Electronic assessment

Introduction

Assessment drives student learning and effort (Kendle & Northcote, 2000) and in turn influences the direction and quality of student learning (Maclellan, 2004). Numerous literature reviews have revealed that feedback is critical to improving the standard of student work and learning (Black & William1998a; Hattie 1999; Heinrich 2006, Huber & Mowbray 2011) and that both formative and summative assessment directly affect student engagement. Assessment designs often include formative feedback aimed at enriching student engagement and understanding of the subject matter. Effective feedback should focus on the individual, outlining strengths and weaknesses and avenues for self-improvement (Linn & Miller, 2005; Heinrich 2006).

Timely feedback is essential for students to use feedback to improve later assessment submissions and focus on learning not marks (Fish & Lumadue 2011; Holmes & Papageorgiou, 2009; Ramsden, 2003). Students prefer feedback embedded throughout the body of their assessment submission (Wolsey, 2004) and the use of criterion-referenced assessment (O'Donovan, Price, & Rust, 2004).

Electronic feedback management systems, such as ReMarksPDF offer opportunities for improvement in assessment practice and outcomes for students and academics, including:

8. E-submission, allocation, marking, moderation and assessment return via a learning management system
9. Efficient electronic assessment workflows built on enterprise level system deployment
10. Extensive annotation and commentary features, including rubrics, audio, video, stamps, electronic dashboards and charts
11. Links to electronic portfolios classified by learning outcomes or graduate attributes
12. Quality management including consistency, reporting, and self-reflection

The ReMarksPDF Project

ReMarksPDF is a feedback management system, available free to Australian academics, designed to operate standalone or as part of an enterprise learning management system. The aim of the project is to significantly improve the quality, quantity and timeliness of assessment feedback whilst decreasing the workload and time commitment of academics associated with the marking of student assessment. ReMarksPDF provides rich media features such as auto text, sound and video comments, colour coding with assigned meanings, self-populating drag and drop graphs and charts, extensive moderation facilities (based on questions, marks, criterion, markers or combinations of these elements), style libraries, advanced rubrics and cover pages. The software is available in English, French, Modern Chinese and Arabic.

The intention is to improve student engagement with their studies through timely detailed feedback embedded throughout their assessment submissions, linked to criterion-referenced requirements.

Trials of the software are currently being undertaken at Griffith University, the University of Western Sydney and by numerous academics nationally and internationally.

Going live: Building academic capacity in blended learning using web-conferencing technologies

Roger Cook
Learning Designer
Queensland University of Technology

Dr Natasha Giardina
Learning Designer
Queensland University of Technology

This paper reports on a current initiative at Queensland University of Technology to provide timely, flexible and sustainable training and support to academic staff in blended learning and associated techno-pedagogies via a web-conferencing classroom and collaboration tool, Elluminate *Live!*. This technology was first introduced to QUT in 2008 as part of the university's ongoing commitment to meeting the learning needs of diverse student cohorts. The centralised Learning Design team, in collaboration with the university's department of eLearning Services, was given the task of providing training and support to academic staff in the effective use of the technology for teaching and learning, as part of the team's ongoing brief to support and enhance the provision of blended learning throughout the university. The resulting program, "Learning Design Live" (LDL) is informed by Rogers' theory of innovation and diffusion (2003) and structured according to Wilson's framework for faculty development (2007). This paper discusses the program's design and structure, considers the program's impact on academic capacity in blended learning within the institution, and reflects on future directions for the program and emerging insights into blended learning and participant engagement for both staff and students.

Keywords: blended learning, web-conferencing, academic capacity building, learning design

Program Overview

The QUT "Learning Design Live" (LDL) program aims to facilitate the strategic institutional goal of improving student learning outcomes by building academic capacity in teaching and learning. QUT's strategic plan explicitly recognises the diverse learning needs of its students, many of whom do not attend - or are not able to attend - formal classes, and states that the university "will seek to provide welcoming, challenging and collaborative environments and experiences in the classroom and beyond" (Queensland University of Technology 2011, p. 4). Moreover, part of QUT's "vision for the future" is specifically "to provide outstanding learning environments and programs that lead to excellent outcomes for graduates, enabling them to work in and guide a diverse and complex world characterised by increasing change" (p. 10).

One of the ways QUT seeks to meet these strategic goals is by employing and fostering blended learning in a range of forms, which are informed by the institution's blended learning policy and associated policies on approaches to learning and teaching and high quality teaching (*QUT Manual of Policies and Procedures* [*MOPP*], 2010). Blended learning may be understood as the combination of face-to-face teaching and learning with online teaching and learning "whereby both face-to-face and online learning are made better by the presence of each other" (Garrison & Vaughan, 2008, p.52). Sharpe (2006) argues that institutions implementing blended learning require "highly contextualised and specific rationales for their adoption of technology" for the implementation to be successful (p. 3). QUT defines blended learning in its own institutional context as "the designed integration of face to face, distance, and electronic approaches to enhance student learning" (*QUT MOPP* 2010, s6.3), which, when taken together with its definition of student learning needs, corresponds to the rationales of "flexibility of provision, supporting diversity, enhancing the campus experience [and] operating in a global environment" as outlined by Sharpe (2006, p. 2).

Building Academic Capacity

The implementation of blended learning and the associated use of educational technologies have the potential to increase access to education and flexibility of teaching, to enhance communication and collaboration, and to create rich learning environments (Miller, Martineau & Clark 2000; Birch & Sankey 2008; Lonn & Teasley 2009). However, building institutional academic capacity in these techno-pedagogies is an essential part of the implementation process, and a range of factors have the potential to influence the success of such capacity-building activities. Many of these factors relate to Rogers' (2003) perceived attributes of innovations: relative advantage, compatibility, complexity, trialability and observability. The research suggests that effective diffusion of innovation in the field of e-learning requires a synchronised fostering of innovation from a top-down policy and leadership perspective together with bottom-up innovation and change (Wilson 2007; Davis & Eales 2007; Cook, Holley & Andrew 2007; Stein, Shephard & Harris 2009). Researchers concur that good communication strategies for awareness-raising and dissemination are vital to the diffusion process (Rogers 2003; Davis & Eales 2007, Zellweger Moser 2007). Arguably, however, this communication should be discursive in form, rather than didactic, and should encourage input by stakeholders at every level and in every part of the process (Davis & Eales 2007; Stein et al. 2009).

One critical requirement for building academic capacity in blended learning is the provision of adequate support for staff, both technical and pedagogical (DeLone & McLean 2003; Zellweger Moser 2007). Ellis and Goodyear argue that "It is rare for an individual academic to have all the knowledge and experience needed to make the best choices among learning tasks, technologies and ways of organising students, and to make sure that these choices are aligned to the best effect" and advocate team collaborations of academics together with educational development and technology specialists to "embrace more complex approaches to educational design, and make use of appropriate design tools and methods" (2010, p. 118), and these are potential benefits which may accrue as a result of the program.

Web-conferencing is a key emerging blended learning tool with its own set of techno-pedagogies, as facilitated through a range of technologies such as Skype, Cisco WebEx, Adobe Connect, and Blackboard Collaborate (Elluminate *Live!* plus Wimba). QUT supports the Elluminate *Live!* tool for use in teaching and learning, which facilitates a range of learning activities with differing levels of synchronicity and interactivity according to Bower, Hedberg & Kuswara's framework of online pedagogies (2010, p. 182). These activities include synchronous and asynchronous lectures, interactive tutorials, face-to-face lectures streamed to external students and containing interactivities such as polling and back-channel chat, remote and interactive guest lectures, document collaboration, virtual meetings and audio-visual assessment feedback. Bower (2011) argues that while the use of web-conferencing systems in teaching and learning may potentially enhance active learning especially in distance learning contexts, the implementation of these tools is a complex process requiring technical mastery and the ability to solve problems in real time, consideration of the pedagogical affordances of the tools separately and in combination, and the careful design of the learning experience to use the most appropriate tools and modes to achieve the desired outcomes (pp. 63-4).

Program Design

The research on innovation, capacity-building and blended learning strategies have closely informed the design of QUT's Learning Design Live program, which is designed to build academic capacity across the university in the techno-pedagogical competencies associated with teaching and learning in technology-enhanced learning environments. In terms of Graham's four levels of blended learning and teaching granularity (2006), the program is informed (and has the potential to inform reflexively) the institutional-level of blended learning, but focuses mainly on building academic capacity in activity-level and subject-level blended learning, while also explicitly considering the implications and possibilities of implementing course-level blending.

The LDL program aims to achieve the following objectives:

1. Raising awareness of the Elluminate *Live!* tool and its pedagogical affordances for blended learning within the university, especially among academic staff.
2. Providing an ongoing program of professional development activities related to blended learning using the Elluminate *Live!* technology which are timely, reusable and targeted, and which staff can access synchronously and asynchronously.
3. Modelling good practice pedagogical exemplars of Elluminate *Live!* usage.
4. Communicating information about associated university support structures, such as resource banks, learning design assistance, Elluminate *Live!* training, IT Help Desk support and audio-visual support.
5. Using the Elluminate *Live!* platform to showcase academic experts, faculty projects and university initiatives related to blended learning.

The program was developed according to Rogers' theory of innovation (2003) and specifically in terms of Wilson's framework for faculty development (2007). The first dimension of this framework is communicating the relative advantage of the innovation specifically for teaching and learning, with Wilson suggesting showcasing and information sessions as possible strategies. This approach is fundamental to LDL as stated in the program's objectives, and is further enhanced by cross-promotion of the program at other university communities of practice, showcasing and information events.

The second dimension outlined by Wilson is demonstrating the compatibility of the innovation with current learning and teaching practices and faculty values. Wilson suggests that "It is useful to start with individual faculty's current perceptions about teaching and learning in relation to their current practice, before examining how use of the new technologies can alter these practices and their role as a teacher" (p. 125). LDL achieves this by identifying current and popular learning and teaching practices and introducing blended learning strategies which complement, extend, enhance or transform these practices in ways which encourage dialogic engagement and reflection by session participants. Similarly, the program responds to the institutional value placed on blended learning for student outcomes, particularly in terms of the diverse learning needs of students, as discussed above. LDL sessions regularly discuss issues of student engagement and strategies to meet students' learning needs through the use of educational technologies and blended learning. However, faculty values are often complex and moreover in a state of constant change, as the cultural and generational contexts of university teaching compete with institutional targets and pressures, strategic initiatives and workload pressures. This has the potential to impact on staff receptivity to innovation, especially in the case of blended learning strategies, and is an ongoing challenge with which the program grapples.

The third of Wilson's dimensions requires addressing the complexity of the learning innovation and workload issues involved in its adoption. For the main part, LDL is not a dedicated training program; however the program aims to address this dimension by introducing the key functionalities of the technologies discussed in each session, including but not limited to Elluminate *Live!*, modelling pedagogical strategies and cross-promoting learning design support and training events. Finally, by its interactive nature, LDL fulfils the "trialability" and "observability" dimensions of Wilson's framework, and indeed, these are perhaps the strongest attributes of the program. As Wilson notes, "Offering faculty development online engages faculty as learners in the online environment, experiencing first-hand the use of the innovation" and this encompasses "encouraging participation in activities where they are using the new technologies themselves" (p. 126). Moreover, using modelling and active engagement strategies in Elluminate *Live!* assists academic staff to develop the required technical mastery, problem-solving skills and pedagogies which Bower (2011) identifies as essential to the successful implementation of web-conferencing technologies.

The program began in February 2010 and runs as a weekly half-hour session during each academic semester. The program targets academic staff as well as professional staff supporting academics in learning and teaching.Wide dissemination of upcoming sessions and previous recordings is achieved in coordination with Assistant Deans of Teaching and Learning in each faculty through regular email communications and in-faculty promotion. The calendar of events and session resources are also communicated via a QUT Blackboard community site housing resources relating to aspects of learning design, emerging technologies and blended learning pedagogies; this site has 304 active members (206 academic staff and 134 professional staff). The sessions comprise a mix of learning designer-led sessions and academic-led showcases of projects, innovations and reflections on practice. Each session models good pedagogical practice and contains technical support information as well as links to further support for the Elluminate *Live!* tool and for pedagogical assistance.

Research Methodology

Data relating to the LDL program was collected in three ways:

1. All participants attending the live sessions were invited to complete a Blackboard survey after the completion of each session (see survey questions below).
2. Those who viewed session recordings had the opportunity to provide unstructured feedback via a Blackboard blog or email. Some email feedback was received and this was incorporated into the survey data.
3. The number of downloads of each session recording was obtained at the end of each semester from Elluminate's Session Administration System.

Survey Questions for Participants in Live Sessions

Participants were asked to identify their role and faculty affiliation and to indicate their overall level of satisfaction with the LDL session they attended by providing feedback on the following specific areas:

1. What were the best aspects of this session?
2. What aspects of this session would you change or add to?
3. Please provide any additional comments about the session.

The collated data was analysed using thematic coding in order to ascertain the effectiveness of the program (to build academic capacity in blended learning tools and techno-pedagogies), to inform further development of the program, and to shed light on the ways that QUT academics are engaging with the challenges, opportunities and issues raised by blended learning, particularly in reference to web-conferencing technologies.

Findings

Statistics of live session participants and recording downloads for sessions is shown in Table 1. All sessions were presented by one or more learning designers (from a team of 9 people including the manager) and sometimes co-presented with a variety of academic and professional staff.

The data reveals two important trends: significantly greater numbers of staff access the recordings than attend the live sessions; attendance levels in the live sessions have declined since Semester 1, 2010; and the number of recording downloads is greater for the earlier sessions, although this possibly reflects the cumulative effect of ongoing downloads over time.

Table 1. Summary of Learning Design Live Statistics (to 21/10/11)

Semester	Sessions	Co-presenters	Range of number of participants in a session	Total participants in all sessions	Total no. of recording downloads
1, 2010	14	2	4-37	165	500
2, 2010	12	12	3-13	109	347
1, 2011	12	6	1-9	50	266

All of the LDL topics presented are listed in Table 2, which shows that some topics have been repeated with a slightly different emphasis (e.g. topics about Elluminate *Live!*, Blackboard Tweaks and community sites).

The most popular sessions (for live and recorded sessions) were those related to the use of Elluminate *Live!*, specific Blackboard issues (e.g. site design, incorporating tweaks into a site and community sites) and particular educational technologies (e.g. PowerPoint, vodcasting and QUT's Open Web Lecture system). The least popular were those repeating past topics (e.g. "Active community sites: development and management") and some generalised topics (e.g. "Learning Design Q&A"). However, it is currently difficult to ascertain the trends in downloads for Semester 1, 2011 as download figures tend to increase over time. A final point to make is that the use of multiple presenters or co-presenters did not seem to influence the overall popularity of a session with respect to attendance or download numbers.

Table 2. Learning Design Live topics and statistics (to 07/07/11)

The numbers of Blackboard surveys completed after each session has decreased each semester from 30 to 13 to 11 for successive semesters. However, useful feedback has been obtained as summarised below.

LDL has received general positive feedback for both the live sessions and recordings:

- *It is great to hear of people using these tools in class and also how students interact with such classroom environments. This was a well paced, informative session with good opportunities to share knowledge and experiences.*
- *I like the choice of joining the session live, especially if I know I might have questions along the way, or viewing the recording at a time that I am available to.*
- *I'm hoping to keep engaging with these sessions (live or recorded!) as I am finding them very useful in terms of introducing new modalities for learning and ways to organise blackboard in more effective ways!*

Participants prefer sessions that are practical, informative, concise and relevant:

13. *I liked the actual practicality of it all.*
14. *This was good: I could follow step by step.*
15. *It was great and really helpful. Lots of useful and practical tips for making my Blackboard site schmicker. Thanks!*
7. *Good overview of the current projects. Links to the material available. Interactive nature, allowing feedback and info to be posted from all participants.*
8. *Very useful mechanism for keeping up with T&L developments.*

Sessions that provide insights into using Elluminate *Live!* received positive feedback:

- *Excellent! Can't wait to use this - it is going to be so helpful working with external students :)*
- *There is always something in Elluminate Live that I find useful and applicable to our teaching and learning contexts. Keep up the good work!*
- *Using Elluminate Live! for the first time and seeing how good it is. And the info was interesting despite the fact that I don't really need to use a lot of it. some more examples of new applications. Very good outline in limited time.*
- *I appreciate the opportunity to participate in the session- I learned a lot! This has really encouraged me to look into ways to use Elluminate in my teaching so thank you. It was also fun!*

Sessions that experienced technical difficulties or were seen to be too difficult, basic or inaccurate were unpopular:

4. *I have noted that a number of LATTE session recordings would be substantially improved by post-production editing, particularly where presenter(s) materials do not work, and/or there are delays or other glitches while the recording process continues.*
5. *It went too fast for me. Should address different skill levels. May be I need a one-to one training with this.*
6. *Too much on basics and not enough on advanced functions. I do not feel it met the objectives of the session.*
7. *I feel I knew more than the presenter covered.*

Conclusions

The most significant benefits of LDL for different stakeholders are listed here:

5. Participants: It has been worthwhile for staff to experience Elluminate *Live!* and other blended learning strategies from a student's perspective before implementing in their own teaching and to engage in cross-faculty discussions and teaching approaches. In particular, academic-led or co-presented sessions promote a diverse range of ideas and teaching approaches both about using Elluminate *Live!* and employing other educational technologies.

6. Learning Design Team: LDL has provided capacity building opportunities for team members since it draws on the strengths and interests of the team, fosters collaboration and has developed the team's skills and understanding of using Elluminate *Live!* for a variety of purposes. It has also helped the team to identify short and long term goals (that align with eLearning Services strategic goals) and helped to build an identity for the team at QUT.
7. Institution: findings from the LDL program have informed policy and guidelines related to blended learning and teaching and assisted in promoting learning and teaching approaches used by academics within and across faculties.

The LDL program is continuing to evolve but has not been without its challenges:

8. Scheduling sessions at appropriate times to maximise synchronous attendance has been only partially successful, given the competing commitments many academic and professional staff must manage.
9. The choice of topics requires constant dialogue with stakeholders but fostering such dialogue is challenging and does not necessarily result in a popular session.
10. We have needed to rethink what to present in the live sessions in view of the fact that most sessions will be viewed as recordings.
11. Technical problems within the session impact negatively on participant experience and potentially impact on staff willingness to adopt the demonstrated tools or strategies; prior testing is therefore of paramount importance.
12. It has been challenging to maintain a community of practice around LDL. Staff have not been as engaged in offering feedback or ideas for future sessions as expected and ways of encouraging this need to be further explored, including greater feedback to participants on survey results.

Reflections

The program has offered insights on the issue of engagement with blended learning. Most notably, it would appear that staff, especially academic staff, share many of the diverse learning needs and interests as their students: for example, they have a range of motivations and expectations of their professional development, they often have competing commitments which impact on their availability for synchronous learning, and they bring a wide variety of technical and pedagogic competencies to the learning activities. Participant feedback and attendance/download statistics indicate that the blended learning strategies employed in LDL have had success in supporting these diverse needs and interests, especially in terms of the different kinds of blended learning strategies covered, the variety of learning activities afforded, and the ability to create both synchronous and asynchronous experiences. However, while the program aims to foster a community of practice around blended learning, the participants themselves often want "just in time" resources rather than investing in ongoing dialogic interactions with colleagues, which is a challenge the program continues to grapple with from a professional development perspective, and also in terms of the implications for student engagement in blended learning.

The dominant trend of much higher rates of session downloads than live attendees brings into focus a key design challenge of web-conferencing and other forms of blended learning where both synchronous and asynchronous participation is possible: that is, to create learning experiences which include interactivities for live participation, yet also foster active learning for participants viewing the sessions asynchronously. As this is also a problem frequently raised by academic staff teaching via web-conferencing at QUT, future iterations of the program will aim to support and develop these important design skills and engage with the more fundamental question of whether the perceived primacy of synchronous learning is necessarily justified. This process will require further evaluation of the impact of LDL, especially in terms of student learning outcomes.

There remains the ongoing challenge of maintaining staff engagement in the program in the long term, which requires new strategies in terms of objectives, design and communication. Some planned future activities in this area of the program will include more face-to-face development and networking opportunities for participants, changing delivery modes to capitalise on physical spaces as an essential part of the blended learning experience, and a re-evaluation of the location and type of support resources provided to staff.

Exploring Medical Students' Use of Technology

Linda Corrin
Graduate School of Medicine
University of Wollongong

The use of Information and Communication Technologies (ICTs) are increasingly important in the delivery of medical education. Whilst the primary motivation for technology integration is to increase learning and teaching effectiveness, such decisions are sometimes based on assumptions of a high level of technological literacy of students entering higher education. Recent literature has challenged these assumptions instead presenting a more diverse picture of students' experience and skill with technology (Kennedy et. al., 2007, Oliver & Goerke, 2007; Margaryan, Littlejohn & Vojt, 2011). This paper presents the results of surveys conducted with new graduate medical students designed to measure access to and confidence with technology. This data has been used by the medical school to monitor the technological profile of each cohort of students in order to implement suitable support activities and to provide an empirical foundation to inform decisions around the implementation of new educational technologies in the curriculum.

Keywords: Medical education, Technology, Digital Natives, Net Generation

Introduction

As medical curricular become more innovative, incorporating a diverse array of learning and teaching activities delivered across campus, clinical and community environments, information and communication technologies are increasingly being used to support delivery. As integration of technology has increased it has become clear that more understanding of students' technology access and use is required to make sure technology is utilised effectively. By providing empirical evidence of students' experience, confidence and access to technology, reliance on the use of generalisations based on the supposed technological attributes of members of this generation of students can be reduced. Such generalisations have been used by some to call for radical change to education to incorporate higher levels of technology (Oblinger & Oblinger, 2005), however others caution that more evidence is needed before change should be considered (Helsper & Eynon, 2007, Bennett, Maton & Kervin, 2008). The discussion around the so-called "digital natives" (Prensky, 2001) or the "Net Generation" (Tapscott, 1998) claim that today's students have grown up surrounded by technology, and therefore would be comfortable with an increase in the use of technology to deliver education.

Studies that have emerged over the past few years have begun to challenge these assumptions and have demonstrated that a significant level of diversity exists in the technological aptitude of the current generation of students (Kennedy et. al., 2007, Oliver & Goerke, 2007; Margaryan, Littlejohn & Vojt, 2011). In terms of medical students, Dorup (2004) found that whilst access and use of technology was increasing over time, not all students wanted an increase use of technology in their studies. Dorup also stressed the importance of building in suitable technology support activities to address the varying levels of ICT literacy. McNulty et. al. (2002) found that medical students' personality has an impact on their use of technology accounting for some of the variation in adoption of technologies.

This paper explores the technology access, use and confidence of medical students entering a new graduate medical programme. Five years of data are presented which show that not all students demonstrate a high level of technology engagement and there is a significant variance in some technology-based activities. This data has been used by the medical school to inform the development of technology support activities and the implementation of new technology in the curriculum. The data provides valuable justification for choices around educational technology and is useful when exploring technological solutions to pedagogic problems.

Background to the medical school

Established in 2006, the Graduate School of Medicine (GSM) at the University of Wollongong offers a four-year graduate medical programme. A strong emphasis of the programme is the development of medical practitioners for regional, rural and remote Australia to help address the shortage of doctors in these areas. The curriculum is integrated and spiral in nature designed around 93 clinical presentations and four themes of learning outcomes: Medical Sciences, Clinical Competencies, Personal and Professional Development, and Research and Critical Analysis. Rather than discrete subjects on each medical discipline (ie. Paediatrics, pathology, etc.), the curriculum develops scientific and clinical knowledge through problem-based learning, body system blocks of teaching, and clinical experience. Students begin their first clinical placements at the end of the first six weeks of the programme and continue clinical placements throughout each of the four phases of the course. The first 18 months (Phase 1) of the course is primarily campus-based, but in each of the other phases the time on campus is minimal with most of the students' time being on clinical placement. In Phase 2 students undertake clinical specialty rotations in the five areas of Medicine, Surgery, Paediatrics, Maternal and Women's Health, and Mental Health. Phase 3 consists of a12 month longitudinal placement in a regional or rural area where students divide their time between general practice, hospital and community clinics. The fourth Phase involves a six week pre-Internship term (usually taken in NSW), a six-week selective term (usually taken somewhere in Australia), and a six-week elective term (can be taken anywhere in the world).

Due to the diverse nature of the curriculum and dispersed locations of the students for the majority of the programme, technology has been used extensively to deliver various elements of the programme. Course content is tagged and stored in a learning content management system (Equella) and delivered to student via a learning management system (Blackboard Vista). The structure of these two systems allows students to access and search all learning outlines and resources delivered to their cohort to date. Each learning activity has an associated outline stored in Equella which sets out the elements of the learning activity including learning outcomes, pre-readings, and associated resources (lecture notes, lecture audio, etc.). The learning activity outlines are also tagged with the associated clinical presentation (from the list of 93), body system, clinical competence, medical science, etc. The GSM also delivers material in the form of Guided Online Assessable Learning (GOALS) objects which are interactive activities that support other elements of the course.

Several tools in the learning management system are also utilized extensively throughout the programme including the quiz tool, assignment submission tool, discussion forums and calendar. The school also makes use of technologies in the classroom including audience response systems (clickers) and video conferencing. The medical degree is taught across two campuses in Phase 1, 6 locations in Phase 2, and across 10 locations in Phase 3, which means that a majority of learning sessions are video conferenced. Another piece of technology integral to the curriculum is the Clinical Log. The Clinical log is a web-based tool designed to allow students to record and reflect on their experiences with patients. The Clinical Log allows students to map their experiences back to the curriculum and looks for any gaps which may need addressing.

In order for students to engage with all of these technologies it is necessary for them to have a reasonable level of technology literacy. As the use of technology in the curriculum increases awareness of the support students may need to gain the necessary literacy has become an important consideration. Surveys such as the one carried out in this study hope to provide timely and relevant data to assist with planning support activities and implementing new technologies.

Methodology

A technology survey has been administered at the start of the year for each new cohort of students since 2007. The purpose of the survey is to profile students' access to and confidence with technology. This data is then used to determine technology support and training requirements for students and to inform new technological innovations in teaching and learning.

The survey has developed over the past five years. Consistent to each year are the demographic questions of age and gender, type of Internet connection, learning management system the students have used in their previous studies and their confidence levels (on a scale of 1 to 7) in relation to using the Internet, email, word processing software, presentation software and audiovisual equipment. In 2009 the survey was expanded to include additional demographics, access/ownership levels of communication devices, frequency of technology-based activities (i.e. online banking, gaming, etc.) and social networking engagement. The categories of technology use for which students were asked to indicate their confidence were also expanded to include more university-related activities such as accessing library resources online, participating in online discussion forums and using statistical software for research. Furthermore, in 2010 questions were added to ask students the operating systems they use on their personal computer. In 2011 questions were added to assist with the planned introduction of podcasting (i.e. identification of students' preferred podcasting software).

Results

The results of the technology surveys over the past five years have shown a steady increase in access to and confidence with technology; however at the same time demonstrate that there remains a variance in individual student's technology access and use. Figure 1 demonstrates that access or ownership of computers has seen an upward trend in students adopting the portable laptop option.

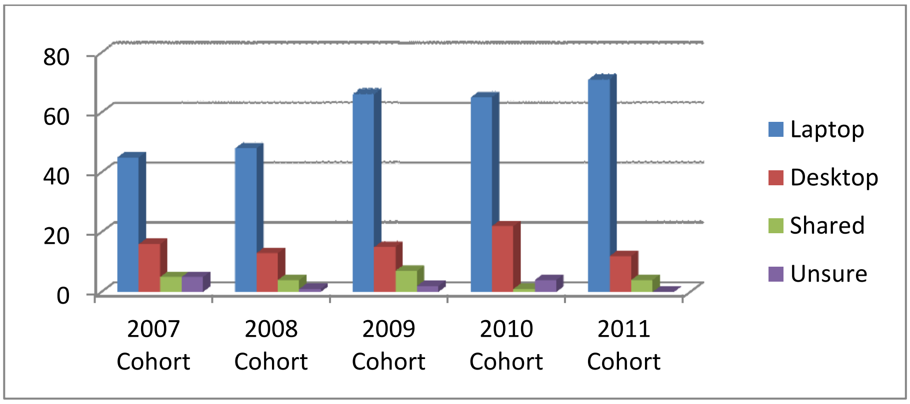

Figure 1: Computer Ownership (2007 – 2011)

Another area that impacts the delivery of the curriculum is the speed at which students can access learning materials. As online learning resources become more interactive and incorporate more audio and visual elements access to Broadband becomes critical. Figure 2 shows that Broadband Internet adoption has increased over the five years with virtually no students left on slower dialup connections.

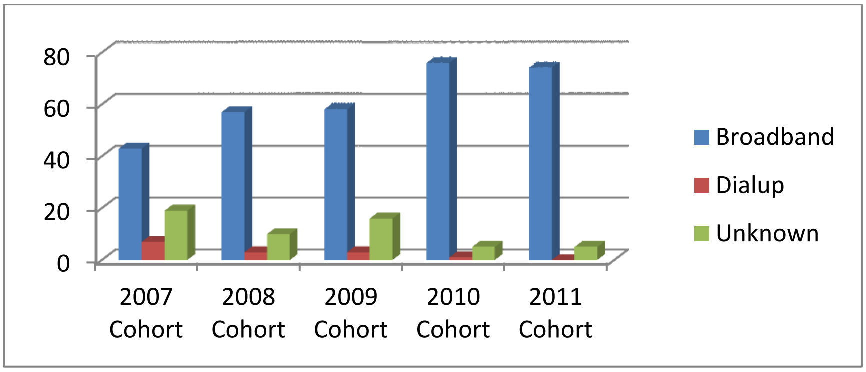

Figure 2: Internet Connection (2007 – 2011)

The rates of confidence with technology showed very little difference from year to year. The figure below shows the results for use of Internet, word processing software, spreadsheet software, presentation software and audio visual equipment as well as an overall rating for confidence with computer skills. Only results from years 2009 to 2011 are presented on this chart as the results for 2007 and 2008 were on a 10-point scale instead of 7. The low levels of confidence with audio-visual technologies are an example of an area that needs to be addressed with further support activities. As so much of the curriculum is delivered via this method, it is important that students are comfortable with its use and able to operate the equipment if required. As a result, video conferencing training sessions are now being run by the faculty's Educational Technology Officer.

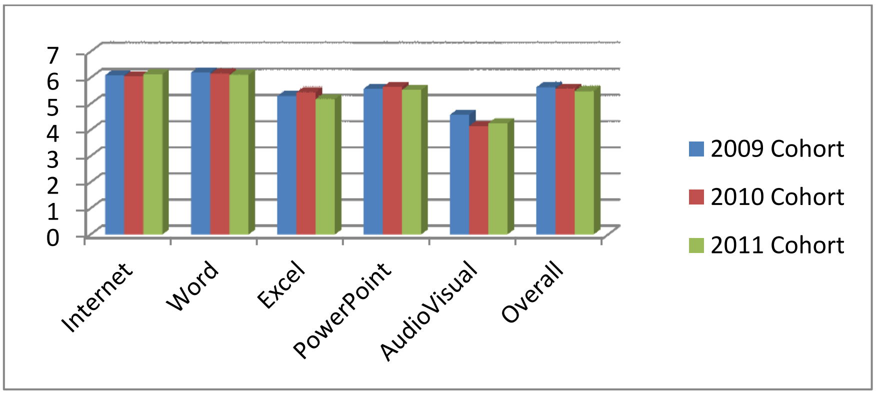

Figure 3: Confidence with technology (2009 – 2011)

Social networking is an area which has shown variance in student engagement. The surveys have shown that social networking has not been unanimously adopted by medical students with 10% of the 2009 cohort, 16% of the 2010 cohort and 11% of 2011 cohort students not accessing social networking at all. In the most recent cohort (2011), 67% of those students that use social networking sites access them daily, 23% weekly and 10% occasionally. These findings are consistent with recent studies which observed many differences in the way students use social software (Valtonen, Dillon, Kacklin & Vaisanen, 2011).

In relation to mobile devices, there have been a number of suggestions made by staff and students for the creation of an iPhone application for systems such as the Clinical Log. However, the mobile phone ownership statistics show that although all students had access to a mobile, only 25% of students owned an iPhone in 2010. Whilst this number grew to 38% in 2011 this still represents less than half of the students in the cohort.

Knowledge of these trends has prompted the Educational Technology team to explore other options for mobile application development including platform-independent options such as HTML5.

Conclusion

The wide variety of technologies incorporated into the medical curriculum creates many opportunities for the delivery of quality education. The use of regular surveying of students to gauge levels technology access and use has proven very useful to the GSM in determining how to maximise and support technology use in the delivery of the curriculum. Orientation to the educational technology elements of the courses is adapted each year based on the results of these surveys and specific student training has been introduced at certain points within the course (i.e. video conferencing training, orientation to the use of the Clinical Log, etc.). Whilst the levels of technology engagement are fairly high across the cohorts, variance still exists in relation to some technological activities (i.e. social networking) and confidence in relation to core delivery technologies (i.e. audio visual technologies). These factors need to be considered when new technologies are introduced and sufficient support resources need to be made available to those students who may need them. Surveying each new cohort will continue in the future with the surveys being adapted to include investigation of new trends and technologies (ie. tablets). In the future it is hoped that the surveys can be run more regularly (i.e. yearly) with each cohort to track and adapt to changes in technology adoption over the four years of the MBBS programme.

Scholarship, leadership and technology: a case study of embedding evidence-based practice

Dr Linda Creanor
Centre for Learning and Academic Development
Glasgow Caledonian University, UK

This case study describes how one university is addressing the challenge of embedding evidence–based practice in learning, teaching and technology by building on the concept of distributive leadership. Following its launch in 2008, the Caledonian Scholars and Associates initiative has firmly established itself as a key aspect of continuing professional development for learning and teaching within the institution, with technology playing a central role. The paper outlines how the initiative has benefitted from the experiences and findings of national and international developments and adapted them to the local context by supporting, encouraging and acknowledging evidence-based practice across the curriculum. It provides an overview of evaluation findings and concludes by outlining future plans to ensure sustainability.

Keywords: evidence-based practice; distributive leadership; embedding learning technology

Introduction

Raising the profile and status of innovative pedagogic practice in higher education can be problematic, due in no small part to the continuing pressure on academics to focus on career enhancement through disciplinary research. Whilst lip service may be paid to the central role of learning and teaching, the culture within institutions often systemically embeds the imbalance, as research, rather than excellent pedagogic practice, continues to attract higher status and remains a central tenet of academic promotion (Vardi & Quin, 2011) Against this background, an emphasis on scholarly approaches to learning and teaching, firmly grounded in evidence, is essential to enhance the standing of pedagogic practice and to increase opportunities for career progression through the learning and teaching route.

For those who pursue innovation through the application of technology, the task of gathering evidence to support career progression can be particularly daunting. Technology enhanced learning frequently stands accused of technological determinism with insufficient evidence or theoretical underpinning presented to support its claims of effectiveness in a learning and teaching context (Oliver, 2011; Creanor & Walker, 2010).

Hence the strategic implementation of evidence-based, technology enhanced practice linked to career progression within the disciplines is perceived as a challenging goal which requires explicit encouragement and support through institutional recognition and influential leadership.

Evidence-based practice can be interpreted in many ways and from a range of perspectives. Originating in the field of medicine, the concept has been widely adopted in education to ensure that pedagogic practice is effectively informed by the findings of high quality educational research (Biesta, 2007). It has often been linked to scholarship in learning and teaching (Boyer, 1990) which Prosser describes as '*evidence based critical reflection on practice to improve practice*' (2008:2). Whereas educational research can be highly theoretical, innovative scholarly activity, underpinned by action research, is firmly rooted in day to day learning and teaching activities (Mills, 2000; Reason & Bradbury, 2001).

The value of evidence-based approaches to the learner experience is undisputed (Jenkins, 2009), however institutional culture, disciplinary context, lack of acknowledgement and recognition can have a significant impact on staff engagement in continuing professional development (CPD) relating to scholarly activity, including technology enhanced learning. Innovative pedagogic practice is often equated with technology enhancement, even though it is recognised that technology can be employed equally to reinforce a traditional, transmission-mode pedagogy as to encourage forward-looking, student-centred approaches (Conole et al, 2004; Beetham & Sharpe, 2007). Tensions continue to exist between pedagogical and technological drivers, resulting in an ongoing struggle to maintain a scholarly focus against a backdrop of constant change and relentless technological advances (Watson, 2001). It is crucial therefore that innovation in learning and teaching is informed by scholarship and a sound evidence base, and promoted by persuasive opinion leaders, if it is to play a truly effective role in the education of 21st century learners.

The aim of this paper is to highlight some of the challenges faced in combining evidence-based approaches with learning technology, influential leadership and career progression by focusing on the experiences of one UK university over a three year period. Firstly, it will outline the background and rationale for a strategic CPD initiative designed to address these issues, informed by relevant national and international developments. It will go on to describe the implementation, outcomes and findings to date, before reflecting on the impact of such an approach and making recommendations for future development to ensure sustainability.

Influencing models and frameworks

Innovation as a concept is problematic within higher education with varied foci encompassing local, often individualised, developments in learning and teaching alongside more managerial and business-oriented institutional and political strategies (Hockings, 2005; Findlow, 2008; Smith, 2011). The relatively short history of learning technology in this context mirrors the variation in conceptual understanding and implementation, with strategies and policies veering between top down and bottom up developments with a similarly diverse range of outcomes.

Large-scale initiatives

In recent times for example, considerable amounts of UK government funding were disbursed by the Higher Education Funding Council for England (HEFCE) to establish 74 Centres of Excellence in Learning and Teaching (CETLs) from 2005-2010, each with a particular pedagogic focus. These centres, many of which incorporated technology enhanced approaches, were locally hosted by the successful bidders but had a sector-wide remit. The dual aims for this initiative were, *'…to reward excellent teaching practice and to further invest* *in that practice so that CETLs funding delivered substantial benefits to students, teachers and institutions'*[4].

In a parallel development in Scotland, the Scottish Funding Council (SFC) invested £6 million in a series of 6 transformational e-learning projects involving both higher and further education partnerships which addressed topics such as assessment and feedback, blended learning and pedagogically-driven approaches to embedding technology in the curriculum[5]. The aim was to effect transformational change in the culture and attitudes of institutions to the integration of e-learning within mainstream learning and teaching.

Whilst success in embedding innovation and evidence based-practice is clearly evidenced by sections of these strategic initiatives (Anderson et al, 2008; VLL Final Report, 2010), an interim evaluation of the impact of the CETLs noted that,

> The tradition of deliberate strategies to change and enhance learning and teaching in higher education in the UK has a relatively short history. Traditionally, its legitimacy among numbers of academics has been uncertain. Central or cross-disciplinary standards, approaches, suggestions and development have run up against the canon of concerns traditionally held by academics. So, academics do not appreciate a heavy central steer on practices that have been very much the local preserve. (Saunders et al, 2008:9)

These findings suggest that despite top-level encouragement and substantial resource, local ownership, empowerment and individual agency remain key influencers of engagement and impact in encouraging creative, evidence-based learning and teaching practice. Without a real sense of long-term commitment to the projects, continuation and embedding beyond the initial funding period is difficult to achieve. (Gunn, 2010a; Bates & Sangra, 2003).

The individual perspective

In contrast to these large scale initiatives, empowering and developing the potential of individual academics is the focus of the Professional Standards Framework for Teaching and Supporting Learning in Higher Education in the UK (UKPSF). Developed by the Higher Education Academy (HEA) in collaboration with the sector, the framework identifies a series of levels and criteria against which an academic's professional development in the scholarship and leadership of learning and teaching can be gauged (HEA, 2006). The framework can be contextualised at a local level, indeed institutions are actively encouraged to do so, and it links to accreditation as an Associate, Fellow or Senior Fellow of the HEA. Although not, as yet, a universally compulsory requirement, an increasing number of UK institutions require new academic staff to attain fellowship of the HEA at an early stage, either by undertaking an accredited programme of study or through a direct application based on experience. The framework is used by institutions to inform their postgraduate certificate programmes in learning and teaching and to shape CPD activities. The UKPSF is currently under review following a sector-wide consultation and while 'the use of appropriate learning technologies' is currently a stated requirement of core knowledge, there is a call for this to be strengthened in the revised version given the increasingly central role of technology enhanced learning in HE[6].

Internationally, the Australian Faculty Scholars Network has also attracted significant interest. Supported by the Australian Learning and Teaching Council (ALTC), it has extended its impact from the initial pilot institutions to a wider group of participating universities. The original aim of the project was to assess the validity of a leadership development capacity framework for teaching and learning (Parrish & Lefoe, 2008). This approach also focuses on individuals and is underpinned by the concept of distributive leadership (Bennett et al, 2003; Knight & Trowler, 2001) which is described by Lefoe et al (2007) as,

[4] http://www.hefce.ac.uk/learning/tinits/cetl/
[5] http://www.sfc.ac.uk/effective_institutions/eLearning/elearning_transformational_change.aspx
[6] http://www.heacademy.ac.uk/ukpsf

> ... a distribution of power within the sociocultural context of universities, and a sharing of knowledge, of practice and reflection through collegiality. (2007:5)

Originally conceived as a way of preparing future leaders in learning and teaching for a rapidly evolving higher education system, this model promotes the development of leadership skills amongst staff who do not necessarily have a formally recognised leadership role in a hierarchical sense. The model has been used successfully to take forward key technology enhanced learning priorities including e-assessment, feedback and online distance learning (Lefoe, 2010; Keppell et al, 2010), with participating staff rewarded with small amounts of funding, partial relief from teaching duties and support through the network of faculty scholars. One outcome of this initiative has been a distributive leadership development framework which, like the UKPSF, can be adapted for a local context. In addition, it was found that participants gained confidence in their own ability to act as leaders and to influence colleagues and senior managers in taking forward key learning and teaching innovations.

> With distributive leadership, those people who may not sit in hierarchical positions of leadership have an opportunity to lead both upwards and sideways among their colleagues and through this mechanism have a real opportunity to influence others and more importantly influence those with power that comes with hierarchical positions of leadership. (Parrish & Lefoe, 2008: 2)

Influenced by, and building on, these examples, the following case study outlines how such models and frameworks have influenced the approach of one UK institution which sought to attain a similar strategic impact through the empowerment of individuals, the embedding of technology enhanced learning and the encouragement of evidence-based practice across all disciplinary areas.

Case study: Caledonian Scholars and Associates

Glasgow Caledonian University (GCU) is a modern, campus-based Scottish institution with almost 17,000 students studying in its three academic schools in the areas of business and society, health and life sciences, and engineering and the built environment. With a significant widening participation agenda, it places a strong emphasis on learning, teaching and the student experience. Nevertheless, promoting recognition for excellence in learning and teaching and encouraging engagement in continuing professional development (CPD) in a meaningful way have been challenging goals, particularly in the fast-moving field of learning technology. Whilst undertaking the University's postgraduate certificate in learning and teaching for higher education (PgC LTHE) programme is expected of all new staff, participation in ongoing CPD for learning and teaching beyond this stage is generally optional and unrewarded. As a result, the University sought to address these inter-linked challenges in an informed way, building on experiences in the sector both nationally and internationally.

Inspired by the successful Faculty Scholars Network in Australia and informed by the HEA UK Professional Standards Framework, the Caledonian Scholars and Associates initiative was launched in summer 2008. It is underpinned by the distributive leadership model outlined above which recognises and encourages localised ownership of innovation and change. The initiative aims to support the implementation of GCU's CPD framework for learning and teaching, which reflects the key priorities of the University's Learning, Teaching and Assessment Strategy and is itself closely mapped to the HEA Professional Standards Framework.

The aims of the Caledonian Scholars and Associates initiative are to,

- provide opportunities for new and experienced staff to maintain continuing engagement with scholarly approaches to learning and teaching throughout their careers.
- enhance learning and teaching practice and the quality of the student experience
- recognise individual endeavour and address a number of promotion criteria through the learning and teaching route
- actively promote innovation in learning and teaching to benefit students, departments and academic Schools

- enable lecturers and staff who support student learning to gain University recognition for commitment to, and investment in, scholarship in learning and teaching.

Technology enhanced learning is integral to GCU's Learning, Teaching and Assessment Strategy (LTAS), the CPD framework and the Caledonian Scholars and Associates initiative. A blended approach has been adopted in which the best of traditional classroom-based teaching is enhanced and enriched, rather than replaced, by the most appropriate use of technology (Bonk et al, 2006). The aspiration is to,

> ...provide a high quality, inclusive and flexible learning and teaching environment which makes the best use of technology enhanced learning, creating a bold, innovative and distinctive approach. (GCU LTAS, 2008)

The Caledonian Scholars and Associates initiative aims to address the twin priorities of enhancing scholarly activity in learning and teaching and developing a more consistent, evidence-based approach to technology enhanced learning.

Implementation

The initiative was launched and facilitated by the Caledonian Academy[7], a central department with responsibility for educational development, blended learning, scholarship and research. Initially two calls were issued each year for Scholar and Associate applications with 7 or 8 awarded successfully at each round, in order to ensure the establishment of a critical mass of activity across the University. This has now been achieved and the call for applications has been moved to an annual basis. All applications must be aligned with the University LTAS and School/Departmental priorities, approved by deans and relevant senior staff as appropriate, and local mentors identified. Applications are peer reviewed by international experts, with final decisions on acceptance made by the pro vice chancellor for learning and teaching based on their recommendations. The criteria for Caledonian Scholars and Associates are aligned with the evidence required for career progression through the learning and teaching route and are explicitly identified in promotion documentation.

A relatively small amount of University funding has been made available for Caledonian Scholars (£2k over two years) and as an additional incentive, workload remission of up to 5 hours per week can be negotiated with School senior management. The number of Scholars accepted at each call is normally limited to a maximum of 7 or 8 due to the level of funding and time resource available. Successful Scholars are expected to be experienced staff who can evidence the following attributes and experience:

- A proven ability to provide leadership and influence peers in the area of learning and teaching, and/or enhancing the student experience
- Be recognised as an opinion leader within their School/Central Department on issues related to learning and teaching
- A desire to engage with a distributive leadership model to contribute to the University's continuing professional development in learning and teaching
- An ability to interpret and identify areas for improving learning and teaching practice in line with the University and/or School/Central Department current LTAS priorities.
- An understanding of the pedagogy of adult learning, and knowledge of available and emerging teaching and learning methods and assessment practices
- A proven record of achievement in educational design, teaching, learning and assessment strategy development, educational technology and/or curriculum development.

Extending the original Australian Faculty Scholars model, a new role of Caledonian Associate was also created in order to encourage less experienced staff who had an interest in becoming more involved in scholarly activity

[7] Following an internal restructure, leadership of the initiative has shifted to the new Centre for Learning and Academic Development

but who perhaps lacked the confidence to undertake an in-depth, two year action research project. Caledonian Associates do not receive funding, but they are entitled to negotiate workload remission of up to 3 hours per week and access ongoing support from the Caledonian Academy team as well as the wider community of Scholars and Associates.

Initially, applications were invited from individuals with a teaching or student-engaged role. This has now evolved to include colleagues working together as joint Scholars or in small teams of Scholars and Associates. The projects undertaken normally use an action research methodology and are linked to the distributive leadership approach. To date there have been 38 projects involving 38 Scholars and 16 Associates spread across all discipline areas, focusing on topics such as assessment, employability, induction and internationalisation. Re-usable learning objects in health, online induction in biology, virtual worlds in cyberpsychology, blogs and wikis in media journalism and online communication in law are just a few examples of projects to date. Although not a requirement for application, technology enhanced learning is strongly encouraged and features in all but a handful of projects. Indeed it seems that by not insisting on a technology focus, the growth of interest in innovation through technology appears to have been nurtured, with several of the Scholars and Associates adapting their projects to include technology following encouragement from other Scholars, colleagues and their students.

In addition to monthly meetings, the growing network of Caledonian Scholars and Associates is supported by an online community where information and resources can be shared and regular blog updates posted. Information on relevant conferences, events and funding calls is made available, and participants are encouraged to bid for additional small grant funding to help ensure the sustainability of their projects. The emphasis has remained strongly on the principles of distributive leadership throughout, with Caledonian Scholars and Associates gradually gaining confidence in their roles as influential change agents and opinion leaders.

Evaluating the impact

Two reviews of the initiative have now taken place. The first was conducted in 2009 at the end of the first year of operation by an external, international reviewer in order to ensure a level of objectivity. Data were gathered from in-depth interviews with participants, with the analysis also drawing upon the reviewer's experience of evaluating the Australian Faculty Scholars network.

Feedback was highly positive, with obvious support for the opportunities presented by the initiative.

> [We have] a huge amount of praise for the project. We've really appreciated all the support…we've been encouraged to look for dissemination opportunities and to use the networks to build capacity.

The report concluded that,

> The Scholars and Associates Program has proved beneficial to participants in a variety of ways in the initial phase. The Scholars were keen to talk about and reflect on their experience, and many useful suggestions were offered for future Program activities. Further value could be realized by harnessing the creative ideas of those involved. Encouraging their leadership as co-creators of future iterations of the Program would be a true reflection of the distributive leadership concept in action. (Gunn, 2010b:7)

The second evaluation was conducted internally the following year, mainly through focus groups with participants and discussions with a range of stakeholders, including the external reviewers who continually provided valuable insights and suggestions to inform the initiative as it evolved. Again, feedback was positive, although a number of challenges were also acknowledged. The findings highlighted the following issues:

Benefits:

- The distributive leadership model which underpins the initiative was seen as relevant and valuable.
- The competitive application process and the involvement of external experts in the reviewing process was welcomed as it helped to confer credibility and status to the initiative
- The 'two tier' system of Scholars and Associates was considered useful as it gave less experienced staff the opportunity to engage with evidence-based practice and action research at an early stage in their careers

Challenges:

- Participation in the initiative can be influenced by the extent to which informal CPD is encouraged and supported in Schools and Departments.
- Variance in approach is evident in the way Schools and Departments address the recommendation for workload remission for Scholars and Associates.
- The role of the School/Departmental mentor is not always clear

A number of changes have already been made in response to these two evaluations including a move towards more strategically focused calls for applications, acceptance of team applications and encouragement for new Scholars and Associates to build on and extend the work of others. School level support issues are also in the process of being addressed as part of a university-wide restructuring exercise.

The initiative has succeeded in gaining participation from staff in all 6 Schools and Learner Support with a particularly high level of engagement from health and life sciences disciplines (figure 1). It was highlighted during a recent Quality Assurance Agency institutional review of the University as a valuable case study and an authentic example of the distributive leadership approach in action.

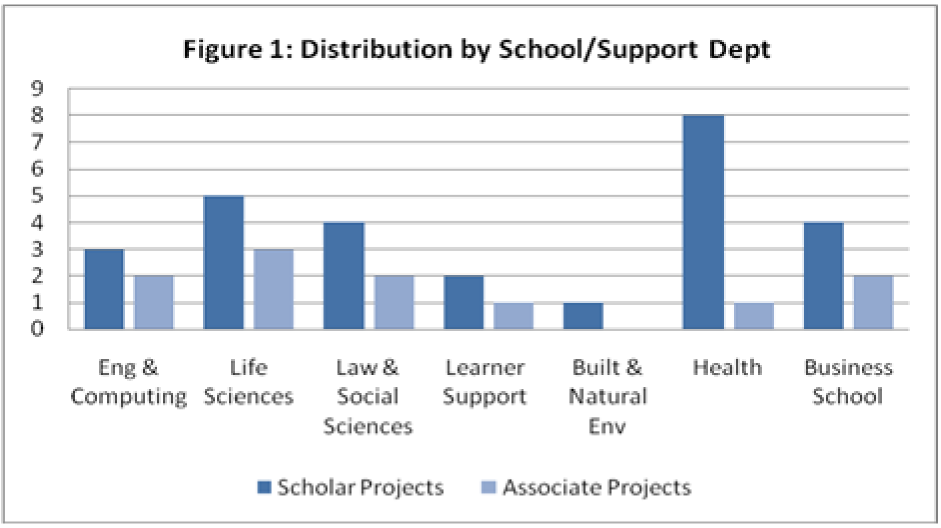

Figure 1: Distribution of projects by School/Support Department

Outcomes

Caledonian Scholars and Associates are required to submit interim and final reports incorporating literature reviews, methodology and outcomes. Findings to date indicate that projects have generally been effective in enhancing the student experience, and valuable recommendations to inform continuing research, scholarly activity and improved practice within modules and programmes have been proposed. In addition, a significant number of national and international conference presentations have been made and papers published in peer-reviewed journals, thus raising the scholarly profile of the individuals concerned and the reputation of learning and teaching at the University. Several Scholars and Associates have been successful in gaining additional small grant funding to extend their projects, both externally through the HEA subject centres and internally through the locally available funding streams.

A key aspect of the Caledonian Scholars and Associates initiative is its alignment with career progression for academics through the learning and teaching route. Several applications for promotion by Scholars and Associates have been successful in the last 2 years, including 3 to senior lecturer and 1 to professor in the most recent (2010/11) promotion round. In addition, a small proportion of Scholars are aligning their projects with doctoral studies. A significant number of Scholars and Associates are either previous graduates of the postgraduate certificate in learning and teaching or current students, demonstrating a clear alignment with progression through the CPD framework. A Caledonian Scholar was the winner of the recently launched (2011) Principal's Award for Teaching, and received particular commendation from the Principal for the creative use of a range of learning technologies. Overall, there is growing evidence of closer links between research, scholarship and academic practice, and a University-wide recognition of their value.

In addition, significant advances are being made in shifting the culture from a technically driven agenda to a more scholarly appraisal of the potential of technology enhanced learning. Literature reviews, action research and a greater awareness of latest thinking in the field are leading to thoughtful, evidence-based approaches which benefit students and teachers alike. Robust approaches to research methodology and data analysis ensure the development of informed and reflective pedagogical practice.

This is evidenced in a variety of ways. One project which focused on the creation of reusable learning objects (RLOs) in health went beyond the original aims by developing a collaborative model for the development of RLOs which can be adapted for use in different disciplinary contexts, and which is attracting interest at a national level through conference presentations. Similarly, a project which focused on induction in the biological and biomedical sciences has drawn on the literature and experiences elsewhere to develop a series of online resources and interactive communication tools for new students which will have an impact beyond the original discipline area. An unexpected by-product has been the involvement of students in developing a series of 'help' videos for the University's virtual learning environment which will be made available to all new students in the coming academic year. A number of the Scholars have also become members of the University's Blended Learning Implementation Group and are actively influencing the development of blended learning across the institution.

Future Development

As the Caledonian Scholar and Associate initiative approaches the end of its third year of operation, consideration is being given to its future evolution. Crucially, there is a need to create continuing opportunities for building capacity in scholarly activity and distributive leadership beyond the completion of Scholar and Associate projects to ensure sustainability (Gunn, 2010a). Whilst it is clear that the distributive leadership model is relevant and effective, it is also evident that given the limited time available for Scholars and Associates to implement their projects during the academic year, leadership activities often only become truly effective on completion of the action research projects. To encourage continuing engagement, a clear pathway for ongoing development is required which builds leadership capacity in learning and teaching while simultaneously strengthening links with personal career development through the learning and teaching route. This is also central to the more advanced stages of the HEA Professional Standards Framework.

The University is now developing a Senior Scholar role specifically aimed at those participants who have successfully completed their Scholar projects or who have demonstrated leadership in advanced learning and teaching activity through a range of other CPD activities. Details have yet to be finalised, but Senior Scholars will have an ongoing remit for embedding innovation in learning and teaching, to further enhance the culture of scholarship in learning and teaching across GCU in line with strategic objectives and continue to build strategic leadership capacity in learning and teaching through cascading their expertise to colleagues .

Conclusion

It is recognised that effecting transformational, cultural and attitudinal change takes time and sustained effort (Garrison, 2011). The university-wide impact of the Caledonian Scholars and Associates initiative is only now becoming increasingly visible following its launch three years ago. During that time, there has been a gradual shift from localised project outcomes to a wider understanding and acceptance of the potential of the distributive leadership model as a means of systematically embedding and rewarding evidence-based practice across the institution. Technology enhanced learning has undoubtedly gained ground as a mainstream learning and teaching activity, underpinned by a growing evidence base and promoted by committed opinion leaders and change agents. Whilst the initiative is facilitated centrally, ownership of projects remain with the participants, their departments and schools, bearing out findings from previous technology-focused transformational change projects that local 'buy-in' is an essential factor in ensuring longer term sustainability(Nicol, 2009; Mayes et al, 2009). The effort expended by Caledonian Scholars and Associates has been acknowledged by peers and by University management, and in several cases, rewarded through promotion, additional funding, student-led teaching awards and an enhanced external profile.

The initiative has not been without its challenges however, primarily with regard to time commitment and internal structural changes. Nevertheless, the ongoing commitment of senior management within the institution to support and expand the initiative is itself evidence of its success to date, as is the fact that this remains a competitive process, providing a valuable stepping stone in scholarly activity for less experienced staff and a means for experienced staff to raise their profile further and improve their prospects for career advancement.

University priorities will inform the future focus and development of the initiative, but the active involvement of staff at all levels within the institution as the living embodiment of distributive leadership principles should ensure an ongoing commitment to scholarly pedagogic practice, evidence-based technology enhanced learning and a high quality student experience.

Bridging the gap – engaging distance education students in a virtual world

Rachel Crease, Bob Pymm & Lyn Hay
Charles Sturt University

Following a review of the provision of courses in the School of Information Studies (SIS) program at Charles Sturt University, academics in the school worked with learning and teaching services to design and implement a variety of teaching and learning activities in the online environment in order to address the challenges of distance education (DE). These challenges included high student attrition, lack of motivation, a sense of isolation and a need for greater and improved communication. A new model of teaching was developed with subject provision now fully online, utilising a range of social networking software, with the aim of creating a more engaging and sustaining learning environment to help overcome the isolation often noted by DE students. This paper outlines the outcome of the course review and reports in particular on one aspect, the development of the SIS Learning Centre in Second Life, where students and teachers meet to engage in new and innovative learning and assessment activities designed specifically to encourage greater communication and connectivity between DE students.

Keywords: LIS education, e-learning, distance education, Second Life

Background

The School of Information Studies (SIS) at Charles Sturt University is the largest provider of degree level education for the library profession in Australia, including teacher librarianship, and graduates around half of all the undergraduate and postgraduate Library and Information Science (LIS) students in Australia (Heazlewood, Pymm & Sanders 2006). The success of CSU's LIS programs has enabled the School of Information Studies to build a relatively large faculty, covering the full range of librarianship specialisations, offering nearly 100 subjects across both undergraduate and postgraduate programs. It was from this position of strength that the School approached a faculty restructure in 2008 that significantly altered its lines of reporting and accountability. This restructure provided the opportunity and incentive to review the existing curriculum of the School, with a view to expanding its offerings, improving the distance education (DE) student experience, reducing student attrition and further cementing its predominance in the Australian LIS education market place.

Distance education: facing the challenges

Since 1989, the School of Information Studies LIS programs have been offered in distance mode only. This suits the School's student profile of largely mature-age students, often with family and work commitments, and fits with the University's commitment to regional education. Distance education, of course, entails a number of challenges for lecturer and student. The challenges that need to be overcome include communication difficulties, lack of student motivation, high drop out from courses, provision of support at a distance and a sense of isolation or lack of student community. For instance, Moody (2004) notes that problems such as the mode of delivery, difficulties in establishing a learning community, and a loss of personal contact diminish the value of distance learning and contribute to high attrition rates. Student feedback over many years both within CSU and in the literature more generally (Yildiz & Chang, 2003; Zhao et al, 2005; Beldarrain, 2006; Keppell, Au & Chan, 2006; Garrison & Vaughan, 2008) suggest that building connections and engagement with lecturers and students are important factors in ensuring a positive student experience when studying off-campus.

The School has consistently sought to meet the challenges of distance education by adopting a range of approaches that will effectively engage the distance learner. That it has been successful at this is demonstrated through the success of the courses in a highly competitive field where over the last 30 years a significant number of LIS schools have closed worldwide(see for instance, Barron, 1991; Saracevic 1994; Willard & Wilson 2004; Ocholla & Bothma, 2007; Partridge, Yates, Hughes & Henninger 2010). It has managed this by responding quickly and effectively to the changing environment within which the library and information professions exist and by maintaining close links with the professions it serves. In order to maintain its leading position in what is a rapidly changing field, it has been essential to ensure course materials and teaching strategies have been regularly reviewed and evaluated. The latest course review in 2008 recommended that the courses and their subjects move to a fully online learning environment, in order to provide the platform for exploiting the affordances provided by increased use of educational technology.

This recommendation was adopted and, during the period 2009/2010, 28 new subjects were created and 25 subjects were reviewed, updated and enhanced to run fully in the online environment. To support this work, the school invested in the services of a full-time educational designer, who worked with the curriculum renewal team on course and resource design. The revised courses were launched at the end of 2009 and the results of their first year in operation are now being assessed. One highly positive result has been that for 2010 and 2011, enrolments at both undergraduate and postgraduate levels have risen considerably – for the first year of offering the revised programs, by 15 per cent at the undergraduate level and 36 per cent at postgraduate level.

Central to the new online model is a student-centred curriculum that enables active and collaborative learning. The subject materials consist of a set of learning modules for each subject, with integrated online activities and resources. The modules are accessed through the subject portal, CSU Interact (Sakai), thus ensuring a consistent and familiar online learning environment for students across subjects. The subject outline, interactive discussion forum and other tools for communication, assignment submission, evaluation and web content are accessed through the same portal.

One of the major reasons for adopting an online model was to address two of the key issues associated with distance education – the amount of reading required and the isolation and lack of a communal student experience. In this new learning approach, student development is fostered by providing an environment that exploits contemporary methods of communication, information seeking and knowledge building through the use of social networking technologies. The success of this approach has been confirmed through the positive student evaluations received for those subjects that most strongly engage with the new model, for example, those subjects exploring technology integration in organisations, social networking and digital preservation. As one student in the digital preservation subject noted,

> 'The *Second Life* component of the subject was highly beneficial, especially for the opportunity to interact with fellow students and academic staff beyond the forum and chat room.'

For some students the technology is challenging at first, particularly in those subjects integrating the use of synchronous learning environments such as *Second Life* (Hay & Pymm, 2011). However, the networks and support enabled by the technology provide an enriched learning environment where they share, build and create knowledge with other students as well as faculty. In effect the technology creates an environment where inquiry and learning can take place more effectively and with more enthusiasm than one in which students study in isolation from others. For many, of course, the a range of communication and collaborative technologies are already part of their everyday communication, social and work life and the online learning environment provided as part of their CSU studies becomes an extension of their experience.

Engaging students in learning

The move to online provision of its courses presented SIS with the opportunity to develop a range of coherent and imaginative resources, designed to engage students and foster deep learning. Embedded across all courses are activities designed to suit many learning styles including online readings, short lectures via podcast and video, screen capture demonstrations, online tutorials and activities from a range of sources, including state and national libraries and so on.

The dynamic online learning model adopted by SIS lends itself particularly well to contributions from guest lecturers – academics or professional experts. Inclusion of lectures and tutorials for instance can be spontaneous and opportunist, where previously they had to be planned well in advance and delivered to students with their mail package on video or CDROM. As in the 'real' world, lectures can be recorded in the virtual world and made readily available so that students with different study patterns, or from different time zones, can access them at times convenient to themselves. It also enables experts from around the world to provide high-level lectures, share their knowledge and experience and participate in discussions which would be impossible in any other way. Given the School's strong links with industry, this more ad-hoc approach allows ready participation from leaders in our field at times that suit them.

Thus the expansion of students' knowledge building is facilitated by the new model which affords far greater opportunities to provide up to date and targeted (just in time) resources. Lecturers and students identify and source new resources as they are required and can provide links, resource lists, sometimes in a wiki, or using a social bookmarking tool such as Delicious or Diigo. Lecturers also respond to students with feedback and examples, using audio, screen capture technology or voice-over slide presentations, and uploading them to the online learning environment. Positive student feedback for these revised subjects has been demonstrated by increased response rates to student evaluation surveys – for 2010 across all subjects these averaged over 40 per cent compared to around 33 per cent in 2008 – with large numbers of targeted free text comments commenting positively on this new approach.

> 'LOVED the variety of formats information was presented in. The mini lectures and weekly chat sessions were sooo helpful' (Student feedback).
>
> 'The inclusion of YouTube videos and weekly lecturer podcasts was wonderful' (Student feedback).

Early in 2009 a number of focus groups were undertaken, involving practitioners, employers, relevant professional organisations and other academics to assist in determining future directions for the course. Flowing from this was strong endorsement for the use of social networking platforms and other relevant Web 2.0 applications in order to try to personalise and improve the distance students' experience of online study, as previously cited in the 'Distance education: facing the challenges' section of this paper. .Thus funding was provided to enable all subjects to be redeveloped, with many of these redesigned to make the most of the opportunities offered by the online world and social networking technologies. Thus consideration was given to the use of blogs, wikis, Facebook, Linked In, Skype, Delicious, Twitter, Flickr, YouTube, Etherpad, SlideShare, TokBox, Amazon Cloud Computing and *Second Life* (Hider, Kennan, Hay et al, 2010).

Learning and teaching in *Second Life*

For this last application, *Second Life*, funding was also provided for the development of a CSU presence in this virtual world in order to exploit the potential for DE teaching offered by such an environment. It was anticipated that the *Second Life* CSU-SIS Learning Centre (as illustrated in Figure 1) built in the second half of 2009, would provide an immersive synchronous 3D learning environment offering the opportunity to further develop student interaction and provide space for new and innovative teaching and assessment activities (Hay & McGregor, 2010; Hay, McGregor & Wallis, 2009).

Figure 1: CSU-SIS Learning Centre (ground level) in Second Life

Second Life is a three dimensional virtual world created by Linden Labs in 2003 which can effectively mirror the 'real' world. Users can join this world by creating a virtual presence via an avatar, or by developing space in the form of an island, a building or even a classroom. Within the *Second Life* environment avatars can talk to each other using text chat and voice (VoIP), and interact with each other using movement, gestures and sound. This environment provides distance education students with an opportunity to meet and participate in discussions, debates and excursions, complete simulations and role-play activities, be involved in virtual tours and quests, and listen to real-time lectures and experience interactions with experts as virtual guest lecturers (Gregory, Willems, Wood, et al, 2011; Gregory, Lee, Ellis, et al, 2010).

Warburton (2009) identified a number of affordances that *Second Life* offers, two of which are of particular interest in the SIS project: extended or rich interactions, and community presence (p.421). A synchronous virtual learning space could help students overcome the isolation factor, develop collaborative skills, and experience creative opportunities, all of which are expected to promote greater engagement and learning.

In order to prepare students for the learning tasks and activities they will encounter in *Second Life*, lecturers provide training sessions in the CSU-SIS Learning Centre. A standard training kit has been developed as part of the Learning Centre design to ensure all lecturers and students are provided with the same training and guidance (no matter what the subject). This helps reduce the preparation for staff in providing training sessions, and allows individual students to revisit the instructional slides and learn how to customise their avatar at their leisure.

Undergraduate and postgraduate social networking subjects are offered across three teaching sessions per year. These subjects require students to complete a number of immersive learning activities as part of the curriculum, with some of these being offered in *Second Life*. Students are encouraged to attend online discussion sessions hosted by faculty and guest speakers; join a range of professional and educator groups; attend professional development activities; visit a range of libraries, university campuses, professional and education spaces; and meet with their faculty for individual consultation regarding project design/management and assessment task requirements. All students are required to maintain an online learning journal as part of the final assessment task to demonstrate evidence of their immersive learning experiences throughout the session.

In order to evaluate the success or otherwise of the student and staff experience in *Second Life*, after one year's experience in its use a formal investigation was undertaken. Three broad questions were determined:

- How did faculty feel about the *Second Life* experience?
- How did students feel about the *Second Life* experience?
- Based on student and academic feedback, what recommendations can be made to improve student and staff experiences, and learning outcomes in *Second Life*?

As a case study, the researchers set out to gather a range of quantitative and qualitative data via end-of-session subject surveys; dialogue captured on subject forums, and SL chat logs; and interviews with subject coordinators and other teaching staff. In total, around 70 students were involved via the surveys and the forum/chat sessions.

Feedback from some students who have not previously experienced a 3D virtual environment highlight the concern that it 'takes quite a lot of time' to become familiar with the *Second Life* client, and as a DE learner, if one cannot dedicate the time required to 'play around with it, then you really … use it on a fairly superficial level'. From a student experience perspective, this highlights the need for educators to ensure the use of a virtual world is carefully considered and integrated part of a subject, rather than merely using it as an 'add on'. Overall, students agreed that the benefits of being connected and 'sharing' the same 'space' are worth the effort within the social networking and preservation subjects at CSU.

Students often compare their *Second Life* experience with those on CSU web forums (which is the principle asynchronous tool used for discussion in most SIS subjects), with the latter paling in comparison, 'you really don't get that intimate sort of learning experience'. The desire to receive one-on-one guidance with faculty or in a small group is also powerful motivator for DE students to 'visit' a 3D virtual campus.

The research team concluded that as a result of their experiences in *Second Life*, they are convinced that it offers a powerful tool to improve the DE experience for all students. The technology is mature enough, most students in developed countries have access to sufficient bandwidth, and growing familiarity with Web 2.0 type tools means that, for many students, it is becoming less of an unfamiliar experience. For staff, there is a significant time commitment required to establish the initial activities but, with growing familiarity and use, this time commitment will fall and the benefits in the shape of improved pedagogies and learning outcomes seems to us clear. At the School of Information Studies, it is considered a commitment well worth making.

Conclusion

Issues relating to engagement with DE students and developing their concept of a learning community have been well documented. Today, the opportunities exist to design subjects and courses in such a way as they can make considerable inroads into alleviating these drawbacks. One such learning environment to assist in this is *Second Life* where the creation of a virtual classroom has proven to be highly successful in engaging students and improving their levels of interaction, and indeed their whole learning experience. Trialled across four subjects, its success has led to a wider take-up among staff and it will be interesting to follow through with further studies as students generally become more familiar with connecting in a 3D virtual world.

Unresolved issues about 'authentic' online learning: Interpretations, assumptions and challenges

Associate Professor Barney Dalgarno
Charles Sturt University

Associate Professor Gregor E. Kennedy
University of Melbourne

Dr Helen Farley
University of Southern Queensland

Mr Mark J.W. Lee
Charles Sturt University

Abstract and Symposium Plan

The focus of the symposium will be a critical exploration and examination of the notion of 'authentic' learning, leading to a discussion of implications and consequences for the design of online learning resources and environments. The symposium will begin with a 5-10 minute overview presented by Barney Dalgarno, in which he will outline a framework containing three specific interpretations of 'authentic' learning, as a precursor to a 5-10 minute presentation by each of the other panel members.

Gregor Kennedy will argue that the concept of authentic learning, although typically operationalised by presenting students with online approximations of 'real-world' tasks and activities designed to promote certain kinds of cognitive processing, reasoning and understanding, often involves the use of media-rich 'skins' as a prelude to the main educational task. Gregor will specifically critique the use of these media skins.

Helen Farley will discuss the potential of 3D virtual worlds as sites for authentic learning, arguing that despite the fanfare, significant shortcomings need to be addressed in order to reliably harness that potential. Helen will examine limitations of virtual worlds including their lack of haptic feedback, inappropriate sensory feedback, and difficulties associated with movement mediated through a keyboard and mouse.

Mark J.W. Lee will discuss authentic learning in open and distance education, arguing that many learners are situated in professional environments offering highly meaningful contexts for learning yet educators often favour fictional scenarios and artificial simulations. Mark will maintain that, in striving to promote learning that is meaningful and relevant to students in their professional lives, the notion of 'creating' an authentic

environment is something of a contradiction in terms.

Finally, **Barney Dalgarno** will draw together these ideas, relating them back to the framework introduced at the outset, before opening the symposium to the floor for 30 minutes of questions, comments and debate.

University of Southern Queensland

Anecdotal evidence suggests that despite recognising the potential benefits of 3D immersive virtual worlds for learning and teaching, many academic staff have chosen not to adopt them, due in large part to the complex array of technical and policy hurdles that must be negotiated in order to make use of such resources within higher education institutions. This paper presents selected results from the questionnaire phase of an Australia and New Zealand-wide scoping study of the use of 3D immersive virtual worlds in higher education. The particular focus in the paper is on findings from the questionnaire about support provided within institutions, technical and other barriers encountered by those considering adoption, and whether and how these were overcome.

Keywords: 3D immersive virtual world, *Second Life*, institutional support, technical issues

Introduction

3D immersive virtual worlds such as *Second Life, Active Worlds* and *OpenSim* have garnered considerable attention and interest in recent years, with many higher educators seeing great potential for supporting and enhancing learning and teaching. In line with this growing attention and interest, studies of uptake and usage of these environments in higher education institutions have yielded evidence of steady growth (see, for example, Dalgarno, Lee, Carlson, Gregory & Tynan, 2010, 2011; Kirriemuir, 2007a, 2009c, 2010b). In spite of this, anecdotal evidence and evidence from the literature suggests academic staff who have used virtual worlds in their teaching have done so despite being met with numerous technical barriers and, in some cases, policy barriers within their institutions. It may therefore be reasonable to assume that there are many other staff who have intended or planned to use the technology in light of its potential learning benefits, but have not done so because of these barriers.

This paper reports on selected data collected from a sector-wide questionnaire administered as part of a scoping study on the use of virtual worlds in higher education in Australia and New Zealand, which is being undertaken by researchers at Charles Sturt University and the University of New England with support from the Distance Education Hub (DEHub at http://www.dehub.edu.au/) consortium. Earlier publications from this project (Dalgarno et al., 2010, 2011; Lee, Dalgarno, Gregory, Carlson & Tynan, 2011) have reported on the range of discipline areas in which respondents have used virtual worlds and the types of virtual world-based learning activities they have designed for their students to undertake. In the present paper, the particular emphasis is on the aspects of the questionnaire data relating to institutional support, barriers encountered and ways in which these have been mitigated or overcome. It is hoped that the findings and insights presented here will be of value to academic staff considering introducing such environments into their teaching by helping them become aware of some of the issues they may face at an early stage in their planning.

Background

The following definition of a '3D immersive virtual world' (hereafter referred to as a virtual world) has been adopted for the present study's purposes:

> a computer-based, simulated environment in which users are able to immerse themselves, and within which they are able to, through their avatars (computer-based representations of themselves or alternative selves), experience, manipulate, interact with and/or create virtual objects and places that are graphically depicted in three dimensions. The objects and places within a virtual world may be modelled according to those in the real world or may be fantasy based. Most current virtual world applications allow for multiple users and include facilities that enable users to communicate and interact with one another within the virtual environment. (Lee, 2010, p. 2)

In 2007, the New Media Consortium's *Horizon Report* (NMC and EDUCAUSE Learning Initiative, 2007) singled out virtual worlds as one of the emerging areas likely to impact higher education within a two to three-year timeframe. The inaugural edition of the Australia–New Zealand version of the *Horizon Report*, which was released in the following year (Johnson, Levine & Smith, 2008), named 'virtual worlds & other immersive digital environments' as technologies to watch with a time-to-adoption of one year or less. The number of virtual worlds in existence is ever on the rise, with numbers predicted by some to exceed 900 by the year 2013 (Mitham, 2008), but Linden Labs' *Second Life* is widely acknowledged as the most popular platform in higher education. Cummings (2010) estimates that approximately 750 institutions operate their own islands in *Second Life*, which does not take into account those that own smaller parcels of virtual land.

Recognising the clear increase in interest in and usage of virtual worlds in higher education and the specific prominence of *Second Life*, Warburton (2009) cautions that the pedagogical promise and value of this new technological environment must be appropriately weighed against the barriers to managing and using it for learning and teaching. He outlines eight broad issue areas that represent barriers relating to the use of *Second Life*, based on a survey of Internet newsgroups, blogs and extant literature:

15. *Technical issues*, including bandwidth, hardware, firewalls, downtime and lag as well as usage problems such as navigation, object creation and avatar manipulation.
16. *Identity issues* faced by users as they grapple with the fluidity and playfulness inherent in identity construction in the virtual world.
17. *Cultural issues* such as the difficulty of finding, developing a sense of belonging to and becoming an active participant of an in-world community, as well as the need to become comfortable and familiar with the codes, norms and etiquette rules of the virtual world.

18. *Collaboration issues* that have to do with the challenges in cooperation and co-construction within a virtual world, and the minimal social networking tools and functions available.
19. *Time issues* and the associated workload impositions on educators in not only mastering the technology but also designing and implementing learning activities and resources that make use of the technology in pedagogically sound ways.
20. *Economic issues*, including the cost of purchasing land, uploading images and textures, buying in-world objects/tools, and employing skilled people to perform building and scripting tasks.
21. *Standards issues*, specifically the lack of open standards and interoperability between virtual world platforms, which limits educators' and institutions' ability to transfer resources between platforms.
22. *Scaffolding persistence and social discovery issues*, the former of which arise from the fact that although the virtual world itself is persistent, persistence for avatars only exists when their users are online, and the latter of which are due to the limited functionality of the in-world profiles associated with each avatar as compared with egocentric social networking services on the Web such as *Facebook* and *LinkedIn*.

Building on the widespread interest and acknowledged potential of virtual worlds, a number of sector-wide and cross-sector reports on their use in education have been published in Europe and North America, but the DEHub virtual worlds scoping study is the first of its kind focusing on the Australasian region. The overseas reports are optimistic about the opportunities and potential offered by the technology, but also highlight a number of challenges and barriers that exist. For example, one of the earliest of these reported on the results of a May 2007 survey run by the NMC (2007) in the United States to collect information on the activities, attitudes and interests of educators in *Second Life*. Of the 209 respondents, 113 (54%) claimed they were involved in an education-related activity in *Second Life*. The respondents to the NMC survey were also asked to describe their most positive and negative experiences in *Second Life*. The positive experiences described related predominantly to the richness of in-world interactions and the opportunities for meeting new people and to expand social and professional networks, in addition to the generosity of the in-world community in offering assistance. Respondents most frequently cited issues of a technical nature, including the steep learning curve required to master the software, as being among the most negative aspects of their experiences.

In the same year the NMC survey was carried out, the US-based EDUCAUSE Center for Applied Research released a research bulletin on *Second Life* in education, drawing on extant literature as well as on interviews with various North American educators and innovators in the area (Kelton, 2007). The diverse examples of virtual world use in higher education showcased in the bulletin demonstrate some of the many applications that are possible. Nevertheless, the author warns that "[h]istory has proven that higher education incurs real risk when entering into a close alliance with a for-profit company when consistency for academic purposes is such an important issue" (Kelton, 2007, p. 9), and discusses a number of obstacles to broad-scale adoption of the technology. He echoes the NMC survey respondents' comments about technical problems and the complexity of using the *Second Life* software, and moreover observes that "[b]ecause those involved with Second Life appear to be having fun, some have come to question it as a serious teaching, learning, or research tool" (p. 8). In a later article Kelton (2008) expands on this discussion, classifying the challenges into four major categories:

- *Perceptual:* This includes challenges caused by the misconception that virtual worlds are all games, as well as other negative ideas about the use of virtual worlds in education that are perpetuated by the mass media.
- *Technical:* While technical issues relating to bandwidth, processing and memory will be overcome with time, two major technical hurdles needing to be addressed at this time, according to Kelton, are the lack of tools for facilitating truly collaborative interactions between users in real time and the lack of interoperability between the different virtual world platforms.
- *Operational:* The three main issues in this category are the need to learn how to use the tool, the occurrence of server downtime and the existence of legal age restrictions.
- *Pedagogical:* This category relates to the educational value and assessment of the technology as well as the intellectual property and ownership issues involved.

The UK Joint Information Systems Committee (JISC) scoping report on 'serious virtual worlds' (de Freitas, 2008) also identified a number of opportunities and challenges facing their use for educational purposes. It named creating more engaging, personalised and student-centred learning experiences, especially for hard-to-reach and unmotivated learner groups as well as those studying at a distance, as a particular area of opportunity, along with providing support for learners with disabilities or mobility issues to help reduce the need for them to travel. Other opportunities suggested by that report include empowering learners to construct their own spaces, content and activities, facilitating cross-disciplinary collaborative research and learning initiatives, as well as mixing or 'blending' virtual and real spaces and experiences. Some of the challenges identified by the JISC report include accessibility and the need for broadband connectivity, the development of open standards, and the provision of support for practitioners in the form of guidelines, case studies and implementation models.

Also in the UK, John Kirriemuir has conducted a number of 'snapshot' surveys sponsored by the Eduserv Foundation examining the uptake and use of virtual worlds in British universities and colleges, the findings of which are documented in a series of rolling reports. Eight reports in the series have been produced thus far (Kirriemuir, 2007a, 2007b, 2008a, 2008b, 2009a, 2009b, 2009c, 2010b) – the first four were funded by Eduserv as individual investigative projects, and the rest were published under the auspices of Virtual World Watch. The eight snapshot reports successively display an upward trend in the numbers of academics and universities that are using virtual worlds, so that by the time of writing the Winter 2009 report (Kirriemuir, 2009c), evidence had been found of the technology being used to some degree at all but one university in the country. The first few of the snapshots in the series pointed to problems in terms of the negative reactions staff using virtual worlds were receiving from their colleagues and peers, but the later snapshots indicated that the situation in this regard was slowly improving over time. Workload levels, funding, resources and support appear to be persistent complaints, as do technical issues, causing the need for staff to put in large amounts of their personal time in order to sustain their projects and efforts in this area. Kirriemuir (2010a) expounds on his findings in relation to technical support in an article published in a special issue of the journal *Educational Research*. Drawing on qualitative data gathered from the first six snapshot surveys, he lists four categories under which comments from respondents about technical issues fell: 'updating the Second Life viewer', 'technical capability' (i.e. hardware, software, network), 'port, firewall and proxy issues' and 'lack of knowledge of virtual world use in education' (on the part of IT support departments). Based on the survey data as well as informal correspondence from academics, he details a number of recommendations in the way of possible solutions to the technical obstructions and limitations, arranged under the headings of 'IT awareness of virtual worlds in teaching and learning', 'national minimum standards for IT innovation support', 'flexibility of high-end IT provision in universities' and 'greater production of support materials and software by Linden Labs'. According to Kirriemuir (2009c), where institutions have managed to overcome institutional technical barriers and support issues, substantive virtual world developments have taken place.

Evidently, despite the substantial interest in virtual worlds among academic staff and the growing body of examples and success stories of the use of such environments in higher education learning and teaching, the international studies reviewed above show that a number of important issues and challenges are frequently encountered. To some extent these issues are similar to those identified in studies of early adoption of other technologies for learning and teaching in higher education. For example, Samarawickrema and Stacey (2007), in a study of adoption of learning management systems (LMSs), found that academic time, technology problems and funding limitations all impacted upon successful adoption. Similarly, in a review of studies spaning five decades in the school education sector, Leggett and Persichitte (1998) pinpoint time, expertise, access, resources and support as key implementation obstacles.

The aim of this paper is to report specifically on the issues faced by academic staff in Australia and New Zealand when integrating virtual world technology into their teaching.

The study

In early 2010, supported by funding from DEHub, the authors began a comprehensive scoping study of the use of virtual worlds for higher education learning and teaching in Australia and New Zealand (see Dalgarno et al., 2010). This scoping study, which will conclude in 2011, involves a systematic review of current and planned applications at institutions across the two target countries, with the goal of capturing and understanding how virtual worlds are being used across universities and disciplines. The present paper reports on a portion of the data acquired from an online questionnaire completed by 117 Australian and New Zealand higher education staff in June-August 2010 as part of the scoping study.

The questionnaire was developed using an iterative process, including pilot testing by 10 respondents prior to the creation of the final version. *SurveyMonkey* (http://www.surveymonkey.com/) was used as a delivery platform for the questionnaire, and it included questions grouped into the following sections: demographic data; views and beliefs about the potential of virtual worlds for learning and teaching; summary information about subjects/units in which virtual worlds had been used; detailed information about a single subject/unit in which virtual worlds were used; and success factors and barriers to the use of virtual worlds in learning and teaching. The present paper draws on the questionnaire items concerning respondents' experiences as they pertain to institutional support and problems encountered, in addition to those soliciting respondents' advice and recommendations for the future. As well as approaching individuals directly via email to request their participation, the questionnaire was made available through various electronic mailing lists/listservs and web-based communities. As an incentive, those completing the questionnaire were able to opt to be placed in a draw for a chance to win their choice of either an 8GB iPod Touch or $250AUD paid as Linden Dollars (the currency used in *Second Life*).

Following on from the questionnaire phase of the scoping study, interviews are currently being conducted with up to 30 people from the questionnaire respondent list in order to allow more in-depth information and insights to be obtained. These interviews are semi-structured and approximately 60 minutes in duration. A cross section of participants from a range of institutions, including academics from various discipline groups, educational designers/developers and IT support staff, are being interviewed. The results from the interviews will be reported in future publications.

Findings

Respondents

The 117 respondents to the questionnaire included 59 males, 56 females and 2 who did not specify their gender. There were 9 respondents in the 26-35 years age range, 40 in the 36-45 years age range, 46 in the 46-55 years age range, 19 in the 56-65 years age range, and 1 in the over 65 years age range, with 2 who did not specify. Of the 117 respondents, 89 were academic/teaching staff, 9 were educational designers/developers, 6 were learning and teaching management staff, 7 were research students or other research staff, and 6 did not specify their job roles. The respondents included 82 from Australia and 35 from New Zealand. 62 of the respondents indicated they had actually used virtual worlds in their teaching, and this group identified 125 discrete subjects/units in which they had done so. These 62 respondents were asked to complete a section of the questionnaire in which they were invited to provide more detailed information about one particular implementation of virtual worlds in their teaching.

Summary of platforms used and support provided

As part of the more detailed information provided about a single implementation of virtual worlds, the majority of participants (49 or 79%) indicated that they had used *Second Life* as the platform, with *Active Worlds* (4 or 6.5%) being the next most commonly used platform, followed by *OpenSim* (2 or 3.2%) and *There.com* (1 or 1.6%). Respondents were also asked whether a virtual world, island or space was developed specifically for the purposes of the subject/unit, and if so, they were asked to provide details. 31 respondents indicated that they had developed a world or space specifically for the subject, while 25 indicated that they had not. An analysis of the additional details provided revealed that 13 of the respondents had purchased new land or space, 12 used an existing space with 7 of these indicating that they had developed new environmental features within it, and 3 rented or borrowed a space, with one of these indicating that they had developed new environmental features. Most of the Australian participants who used an existing island or space indicated that their institution owned it, while a number of New Zealand respondents indicated that they used land provided by the SLENZ group (see http://slenz.wordpress.com/).

Respondents were asked whether they had drawn on the support of other staff within their institution, and if so were asked to give details. 31 respondents specified that they had drawn on such support, while 25 specified that they had not. In providing details about who provided the support, 16 listed IT support staff, 9 listed educational designers, 6 listed academic colleagues, 3 listed casual staff or students, 2 listed project officers and 1 listed library staff. Respondents also listed 10 categories of support provided. Consistent with the fact that the most frequently cited support role was IT support, almost all of the categories of support related to IT aspects of the work rather than pedagogical aspects. Specifically, 9 mentioned the solving of connectivity or firewall issues, suggesting that many university networks do not readily allow the use of virtual worlds. Additionally, 8 mentioned that they had received support with the development of the environment, which perhaps illustrates that developing environmental features within a virtual world is still not something that most academics can be expected to do themselves. Other categories of IT-related support included support with installing and configuring software (5 responses) and the provision of ongoing technical support (4 responses). Non-IT categories of support that were identified included the running of workshops for staff or students (3 responses) and pedagogical support (1 response).

Respondents were asked whether they had obtained dedicated funding to support their implementation and/or use of virtual worlds in the subject/unit, and if so were asked to provide details. 30 respondents indicated that they had received funding, while 26 indicated that they had not. The funding sources described were categorised according to whether they were research (5 responses), learning and teaching (13) or not specified (7), and whether they were internal within the institution (11), external (3) or not specified (11). The most commonly described grant source was internal learning and teaching grant funding (8 responses). The fact that more than half of the respondents had relied on some sort of funding beyond the normal funding allocated for teaching implies that the use of virtual worlds is still at the early-adoption stage. If and when it becomes more mainstream and grows into a standard component of the university teacher's technology toolkit, it is conceivable that the need for separate, dedicated funding and support will fade.

Limitations identified and problems encountered

Respondents who described a particular implementation of virtual worlds were asked to describe the main problems and stumbling blocks that impeded their efforts. In addition to this, all participants were asked to list up to five general limitations/disadvantages of virtual worlds for university learning and teaching, the three most significant barriers and the three most critical success factors in the implementation and use of virtual worlds in university learning and teaching. There was considerable overlap in the answers to these four questions, so they were coded using a common set of categories. 26 categories were identified and these were then clustered into 7 higher-level categories: technology (see Table 1), support, funding and time (see Table 2), usability and familiarity (see Table 3), equity and ethical issues (see Table 4), inherent limitations of virtual worlds (see Table 5), acceptance of virtual worlds (see Table 6), and management and planning (see Table 7).

The most frequently mentioned problems were those under the broad category of technology. As shown in Table 1, the main technological problems identified were lack of sufficient bandwidth, firewall issues, hardware requirements and audio problems. In alluding to bandwidth as an issue, most did not specify whether the problems were at the student's or the institution's end, but it appears from the wording used (e.g. "broadband issues") that they meant home rather than university Internet bandwidth. A number talked about poor performance as an issue, which was in some instances put down to the bandwidth and in others to the computer hardware used on campus. An additional technological problem reported in several instances was difficulties in getting in-world audio communication to work. More general technological problems represented in the data included reliability of student Internet access and problems with students getting the virtual world software to work on their computers off campus.

Table 1: Technological problems, limitations and success factors

Category	Number of mentions as a limitation	Number of mentions as a barrier	Number of mentions as a success factor	Number of mentions in relation to a particular subject
Bandwidth	47	19	6	14
e.g. *"limited to people with broadband Internet"* *"connecting from home always presents the user with problems in our regional area"*				
Firewalls and other IT policy issues	34	31	18	10
e.g. *"campus IT infrastructure limitations (bandwidth, security firewalls, etc)"* *"firewalled at the University so all work by the respondent done at home after hours"*				
Hardware requirements	25	11	8	6

e.g. *"availability of computers with the necessary system requirements whether they be university or the students' own computers"* *"some students did not have the technology to enable them to enter Second Life which is why it could not be compulsory"*				
Audio problems	2	0	2	4
e.g. *"initial problems with voice for some students"* *"there were technical issues of trying to get students to talk (in real time) to each other (voice and text)"*				
General technology requirements or problems	32	18	10	9
e.g. *"some students weren't able to get their software to run on their computer"* *"challenges in configuration of applications on desktops"*				

Table 2 lists issues associated with lack of support, funding or time to devote to the activity. A distinct message here is that successful implementation of virtual worlds requires management and IT support together with additional funding, coupled with substantial time commitment from the lecturer. It is not clear from the responses the degree to which the availability of land through the SLENZ group was helpful to New Zealand participants in getting started with the use of virtual worlds in their teaching, but one might expect that it may have at least partially reduced the funding needed at the initial stages.

Table 2: Support, funding and time related problems, limitations and success factors

Category	Number of mentions as a limitation	Number of mentions as a barrier	Number of mentions as a success factor	Number of mentions in relation to a particular subject
Time commitment	25	23	17	5
e.g. *"commitment and enthusiasm of lecturer for that mode of pedagogy"* "[lack of] *time to devote to project"*				
Cost and funding	19	26	12	4
e.g. *"cost to students and institutions (Internet charges, land rentals, etc)"* *"lack of resources to keep application current and well supported in a teaching context"*				
Management support	5	7	11	0
e.g. *"support from intuitional management/ IT department on board – i.e. the infrastructure issues"*				
Resources – general	0	0	6	0
e.g. *"sufficient resources to build something worthwhile"*				
Support – general	16	16	32	4
e.g. *"support across the university from academic and general (IT support) staff"* *"lack of understanding/help from IT support"*				

Table 3 lists the problems identified that were linked to staff or student ability to use the relevant software. Some referred to students' IT skills as the major problem, while others cited their own learning curve or the lack of familiarity of their academic peers as an issue. Still others laid blame on the software's usability.

Table 3: Usability and familiarity problems, limitations and success factors

Category	Number of mentions as a limitation	Number of mentions as a barrier	Number of mentions as a success factor	Number of mentions in relation to a particular subject
Student user familiarity and learning curve	24	7	5	8
e.g. *"getting students au fait with the mechanics of the 3D world, how to move around ..."* *"students slow to acquire requisite control of the technology and interface"*				
Academic user familiarity and learning curve	12	13	8	3
e.g. *"many lecture*[r]*s are still new to us*[ing the] *3D environment"* *"colleagues are generally 'scared' of learning to use SL* [Second Life]*"*				
General user familiarity and usability of software	13	7	8	8
e.g. *"complex software that is difficult to learn"* *"challenges with setup and the proficiency learning curve / intuitiveness"*				

Table 4 summarises responses relating to ethical or equity issues. These included inappropriate behaviour by students and others in the virtual world, the problems of obtaining institutional clearance to use virtual worlds in teaching, and the difficulty of ensuring all students had access.

Table 4: Equity related and ethical problems, limitations and success factors

Category	Number of mentions as a limitation	Number of mentions as a barrier	Number of mentions as a success factor	Number of mentions in relation to a particular subject
Ethical issues	23	3	1	1
e.g. *"possible griefing by rogue users"* *"supporting unsocial character development"* *"getting ethical clearance to use a 'social networking' tool with students"*				
Equity issues	3	3	0	0
e.g. *"access and equity – financial and age restraints"*				

Table 5 summarises responses identifying inherent limitations of virtual worlds as tools for learning and teaching. Issues highlighted included problems with communicating through an anonymous avatar and limits in non-verbal communication in a virtual world, a lack of clarity about the actual learning benefits of virtual worlds, limits in the authenticity or fidelity of visual simulations in a virtual world, and the potential for students to be distracted by the game-like appearance of a virtual world or by irrelevant objects and avatars within the world.

Table 5: Inherent limitations of virtual worlds and associated problems, limitations and success factors

Category	Number of mentions as a limitation	Number of mentions as a barrier	Number of mentions as a success factor	Number of mentions in relation to a particular subject
Limitations of communication mode	18	1	1	0
e.g. *"not being able to identify people outside of the avatar appearance"* *"interaction is very much through an interface, face-to-face behaviour and practices could be lost"*				
Need for clarity of learning benefits	9	8	16	0
e.g. *"needs to provide opportunity not possible in other methods"*				
Limits in the authenticity of the representation	4	0	0	0
e.g. *"possible missing of steps in real world process unless the virtual experiment is set absolutely accurately"*				
Student distraction by virtual world or game like appearance	6	0	0	0
e.g. *"technology can distract from learning"*				

Table 6 lists problems associated with student or academic acceptance of the potential value of virtual worlds for learning and teaching. A recurring issue here seemed to be the fact that students and other staff often did not initially see in-world learning activities as something to be taken seriously.

Table 6: Acceptance of virtual worlds and associated problems, limitations and success factors

Category	Number of mentions as a limitation	Number of mentions as a barrier	Number of mentions as a success factor	Number of mentions in relation to a particular subject
Student acceptance	15	7	9	8
e.g. *"student reluctance to use the technology"* *"students were concerned about the validity – saw it more as fun than as a learning tool"* *"students thought it was weird and decided against it"*				
Academic staff acceptance	11	6	13	1
e.g. *"when it is not valued by current assessment, students and staff do not usually value it"* *"general scepticism of other faculty"*				
General acceptance	8	17	6	2
e.g. *"bad press of VWs – although dropping off",* *"resistance to a new paradigm concerning teaching and learning"*				

Table 7 summarises responses in which management and planning issues are highlighted. The need for careful and considered planning in terms of the design of both the environment and the learning activities was heavily represented in the questionnaire data. Difficulty in organising for students and staff to be able to synchronise given their diverse locations, time zones and commitments was another recurring problem identified. Many respondents stressed the importance of opportunities for professional development and for sharing and collaboration between teaching staff involved in the use of virtual worlds.

Table 7: Management and planning associated problems, limitations and success factors

Category	Number of mentions as a limitation	Number of mentions as a barrier	Number of mentions as a success factor	Number of mentions in relation to a particular subject
Planning for learning (content, outcomes, timelines)	12	1	32	0
e.g. "[need for] *clear purpose and goals in the implementation*"				
Design and development of the environment	10	0	7	0
e.g. *"creation of useful, repeatable simulations can be difficult"*				
People synchronisation issues	6	2	0	0
e.g. *"time zone differences can make synchronous participation challenging"*				
Continuity as subject is revised and/or teaching staff changed	0	3	0	0
e.g. *"the way courses are passed from lecturer to lecturer inhibits continuity"*				
Need for workshops, meetings, training	0	0	6	0
e.g. *"professional development of staff that includes pedagogical changes and task modification needed to maximise new learning opportunities in 3D"*				
Need to collaborate with others	0	0	5	0
e.g. *"good support from educational community and good contacts with relevant people"*				

Solutions offered

Respondents describing a particular implementation of virtual worlds in university teaching were asked what they had done or planned to do to overcome these problems. All respondents were also asked what additional advice and/or recommendations they had for other university colleagues contemplating the use of virtual worlds for learning and teaching. Responses to these two questions were coded using a common set of categories and the results are summarised in Table 8. Interestingly, although the vast majority of the problems identified (see tables above) were technology related, the most frequently mentioned recommendations had to do with professional development (primarily suggesting that the more professional development undertaken by the lecturer, the better), followed by recommendations related to learning design (a common theme here being that the use of virtual worlds requires a clear pedagogical purpose). There were, however, a number of recommendations related to the virtual world platform (often suggesting a move away from *Second Life* to other platforms), IT support (especially the need to obtain approval to bypass or 'punch through' the firewall) and computer laboratory infrastructure. The value of research, scholarship and networking were also underscored, along with the need for ongoing time commitment and for thorough planning.

Table 8: Recommendations and advice

Category of recommendation	Number of times mentioned in relation to overcoming problems in a particular subject	Number of times mentioned as additional advice or recommendation
Professional development	11	6
e.g. *"I will continue to learn as much as possible myself so as to enable me to reduce my reliance on technical assistance"* *"Attend classes, meetings, events and explore in the virtual world to learn from others and don't limit this to universities"*		
Learning design	6	8
e.g. *"Continue to develop lesson designs, tools, the environment and the bots to the point where they overcome the ... challenges and enable the learner experience of interacting with the environment"* *"Has to be a purpose for the learning other than simply being in SL* [Second Life]*"* *"We used machinimas to overcome the problems we encountered during the design stage"*		
Technology infrastructure	8	1
e.g. *"Put in a case for a new lab with equipment designed to facilitate SL* [Second Life] *teaching";* *"Provide open access to labs were students can practice and play in SL* [Second Life]*"*		
Virtual world platform	8	0
e.g. *"Moved to an open source platform (Project Wonderland) so we could work with Java and not pay a third party for ... land"* *"moved to OpenSim on a LAN to avoid dealing with Linden Labs"*		
IT support	5	3
e.g. *"Made submissions to ICT regarding access – firewalls are supposedly coming down* [next year]*"* *"collaborative approach to dealing with the politics of getting it through the damn firewall"*		
Research, scholarship and evaluation	5	3
e.g. *"More focused research to explore the factors effecting 'intuitiveness' as it pertains to Second Life and medical education"* *"One current 3D MUVE project has benefited from the experiences of the earlier encounters and this has resulted in design elements helping to facilitate student engagement"* *"Read what others have done in this field"*		
Networking	3	5
e.g. *"I networked with other people using Second Life in education, in particular the New Media Consortium"* *"network and connect with the 'experts' and mentors who are already using VWs in education"*		
Policy and support	2	6
e.g. *"Attempted to explain to the gatekeepers that if innovation is desired then gates must be opened and barriers removed"* *"Give yourself time and get support"*		
Time and commitment	2	5

e.g. *"It takes time to get on top of the virtual world and its capabilities but once you have reached a sufficient level of familiarity the potential for creating engaging and effective learning experiences is boundless"* *"Also be prepared to commit substantial time to the effort, but have fun in doing so"*		
Planning	0	3
e.g. *"Make sure that resource requirements (R&D, support, hardware, software) for a proposed system are detailed and costed in advance"* *"Plan everything. Have a Plan B, and a Plan C, and a Plan D"*		

Discussion and conclusion

This paper has provided a summary of the experiences and perspectives of 117 respondents to a questionnaire relating to the use of virtual worlds for higher education learning and teaching in Australia and New Zealand. In particular, the paper has summarised the platforms used, the problems and limitations encountered and the solutions to these problems offered by the respondents. Many of the problems and limitations identified by respondents – including 'time commitment' and 'support' – are reminiscent of those that have emerged from other university technology-adoption studies (e.g. Wilson et al., 2000; Kilmon & Fagan, 2007; Samarawickrema & Stacey, 2007), while others relate more specifically to the use of virtual worlds – for instance, 'limits in the authenticity of the representation' and 'student distraction by virtual world or game-like appearance'.

As with earlier studies and reports from other countries (see, for example, Warburton, 2009; Kelton, 2007, 2008), the most frequently reported problems in the present study were technological in nature, with bandwidth and firewall issues along with hardware requirements to use the client software being the most commonly raised. Another issue identified by many respondents related to the learning curve students and academic staff are confronted with as they attempt to become adept at using the software; this mirrors findings from the NMC (2007) survey. Evidence from other studies suggests that these technical and usability challenges will gradually be overcome, and research and development initiatives around the world are yielding useful, evidence-based resources such as practical guides and handbooks to assist academic staff in their use of virtual worlds in their teaching (see, for example, de Freitas & Rebolledo-Mendez 2008; Savin-Baden, 2010). Nevertheless, it is apparent that from a technical perspective, online learning and teaching cannot be undertaken as seamlessly in a virtual world as it can when using other more established technologies provided within institutional LMSs.

The theme of institutional support was also prominent in the questionnaire responses, including both the need for management support and provision of resources as well as the need for ongoing technological support. A related issue that emerged was the need for funding for virtual environment development and additional time allocation for teaching staff. These issues were also emphasised by Warburton (2009), as well as by Kirriemuir (2010a) in his article on UK university and college technical support for *Second Life* developers and users and in his various snapshot reports. It is important to additionally note that the questionnaire was administered during 2010, prior to the decision by Linden Labs to remove educational discounts on the purchase and rental of land in *Second Life* (Linden, 2010). Consequently, it is likely that cost issues are even more pronounced for higher educators now than they were at the time when the data were collected.

Similar to the findings of Kelton (2007, 2008), an additional problem commonly reported by the questionnaire respondents in the present study was a lack of acceptance by staff and students of virtual worlds as legitimate or 'serious' learning tools. This had implications for a number of respondents, as manifested in a lack of 'buy in' on the part of students and other academic staff. Like Warburton (2009), who described problems with students being unfamiliar with the behavioural norms of virtual worlds, a number of respondents identified anti-social in-world behaviour as a concern. These types of problems are likely to remain while the use of virtual worlds is an activity undertaken only by a small proportion of the population, but could be expected to diminish as usage becomes more mainstream. Bowers, Ragas and Neely (2009), in a study of post-secondary instructors' adoption of virtual worlds, found that 80% of respondents were in either the first ('innovators') or second ('early adopters') stage of Rogers' (2003) five stages of technology adoption. Findings from Kirriemuir's UK-based snapshot reports (see, for example, Kirriemuir, 2007b, 2010b) imply that there are specific issues faced by these early-stage adopters.

Solutions and recommendations for the future offered by respondents included the need for professional development, clear planning from both a technological and pedagogical perspective, and networking with other educators with experience in the use of the technology. It is prudent to note that despite the emphasis in this paper on the negative aspects of respondents' experiences, elsewhere in the questionnaire, they were asked about the degree to which a series of possible learning benefits actually occurred during the implementations of virtual worlds they described. Their responses to these questions were highly favourable – for example, 93% of respondents expressed agreement with the statement "the use of 3D immersive virtual worlds was motivating and engaging for students", 84% agreed with the statement "the use of 3D immersive virtual worlds led to more effective collaborative learning", and 87% agreed that "the use of 3D immersive virtual worlds allowed learners to learn through experiences in context". There is evidence to suggest that many of the problems and obstacles respondents faced were to a large extent surmounted, and from their perspective, valuable student learning can and in fact did occur.

Leveraging technology for engaging learning design

Ashwini K Datt

University of Auckland

Trudi J Aspden
School of Pharmacy
University of Auckland

Web 2.0 tools alone do not teach or result in effective or meaningful learning. A review of literature on evolving learning designs based on the tenets of Pedagogy 2.0 (Lee & McLoughlin, 2010) highlights four contributing elements of design for socio-constructivist learning environments: authenticity, motivation, scaffolding and skills development. This paper details an innovative learning design for the integration of technology to provide flexible access and encourage engagement while facilitating the development of knowledge management skills in an undergraduate course. A combination of technologies and strategies were used to encourage students to sufficiently engage in the assessment tasks. These were: course website for information provision, WebQuest for scaffolded instructions, wiki for collaboration and social bookmarking for sharing and reviewing references. The evaluation of the learning design was generally positive with students reporting increased 'tech savvyness'. However, a significant challenge was facilitation of equitable and synergistic group work which is central to socio-constructivist learning designs. Future iterations of the design will focus on this aspect in addition to encouraging student engagement with the Web 2.0 tools that were underutilized this time.

Keywords: Web 2.0, Pedagogy 2.0, digital literacy, learning design, personal knowledge management, WebQuest

Introduction

Technology integrated teaching is always a challenge, even more so when teaching first year courses. Assumptions are made about the digital literacy and technical skills possessed by students. The notion of them being 'digital natives' (Prensky, 2001), or the 'net generation' (Oblinger & Oblinger, 2005; Tapscott, 1998) assumes that they are skilled at using and adapting technologies for educational use. However, educational researchers are increasingly discovering that these 'digital natives' or the 'net generation' possess technical skills to utilize technology for social interactions and networking but not for educational gain (Cigognini, Pettenati & Edirisingha, 2010; Kennedy et al., 2007; Narayan & Baglow, 2010).

The current and potential use of social software in tertiary education has been well documented (Bates, 2010; Bower, Hedberg & Kuswara, 2009; March, 2007; Lee & McLoughlin, 2010). The literature predominantly describes a socio-constructivist perspective that promotes greater learner control of the learning environment, making learning in the Web 2.0 world more social and collaborative. In the socio-constructivist pedagogy, actively engaged students learn by sharing information through participation in collaborative and cooperative activities (Sthapornnanon, Sakulbumrungsil, Theeraroungchaisri & Watcharadamrongkun, 2009). Group work is a major strategy used to facilitate such sharing of information. It also enables co-construction of knowledge and understanding that capitalizes on the peer-peer interactions and productive elements of the dialogic and constructionist pedagogies as well (see Figure 1).

Web 2.0 tools alone do not teach or result in effective or meaningful learning. "[T]here must be particular purpose or rationale for their use, and teacher support and guidance…are still…essential" (Bates, 2010, p29). Contemporary educationalists agree that technological development in parallel with evolving pedagogies optimize the opportunities afforded by Web 2.0 (Bower et al., 2009). The evolving pedagogy, framed as Pedagogy 2.0 (Lee & McLoughlin, 2010) shifts focus from knowledge acquisition to knowledge transformation (creation and building) in authentic, motivating and well scaffolded learning environments that still maintain strong connections to curricula.

Pedagogy 2.0, while enabling "new pathways to learning with peers" (McLoughlin & Lee, 2010, p59), gives prominence to the "cultivation of digital competencies in ways that allow learners to develop their critical thinking, knowledge building and creative skills" (p60). Consistent with this is the increased emphasis being placed on embedding academic literacies (including digital and information literacy) into the curriculum (Gunn, Herne & Sibthorpe, 2010) to enable learners to take full advantage of Web 2.0 technologies by developing their skills and abilities to search, retrieve, analyse, evaluate, organize, create and share information (Bates, 2010; Cigognini et al., 2010; McLoughlin & Lee, 2010).

According to Lee and McLoughlin (2010), teaching and learning with tools that are otherwise used in social contexts requires teachers to "demonstrate its relevance and to adopt innovative approaches that take advantage of the unique capabilities and affordances of these tools". Alam & McLoughlin (2010) go as far as saying that as educators it is our "moral and ethical obligation to … maintain a participatory and inclusive attitude in pedagogy and in learning environment design." This re-affirms our belief that the success of technology integrated teaching does not solely depend on the affordances of technology but more so, on the influences of the target audience's ability to access, review, use, and manage information. How do we make the best possible use of Web 2.0 technologies to meet our needs and student demands for technology integration while taking into consideration their varying levels of skills (Ryberg, Dirckinck-Holmfeld & Jones, 2010) and digital literacy?

Focus

Web based technologies such as podcasts, online lectures, online discussions, and more recently Web 2.0 applications are increasingly being used by schools of pharmacy to provide effective learning opportunities for pharmacy students (DiVall, 2008; Estus, 2010; Miller, 2009; Swu-Jane, 2007; Sthapornnanon et al., 2009).This paper details an innovative learning design for the integration of technology to provide flexible access and encourage engagement while facilitating the development of knowledge management skills in a group assignment of an introductory pharmacy course.

Definitions

For the purposes of this paper:

- Web 2.0 applications are social software that allow multiple users to collaborate via sophisticated, interactive interfaces to develop micro content that is usually openly available (Alexander, 2006 cited in Bower et. al, 2009).
- Pedagogy 2.0 is the "conceptualization of teaching that is focused on participation in communities and networks for learning, personalization of learning tasks and production of ideas and knowledge" (McLoughlin & Lee, 2010, p 68).
- Scaffolding is the conceptual framework for learning support that enables students to perform better than they would otherwise do in the absence of any type of support (Cho & Jonassen, 2002 cited in March, 2007; McLoughlin, 2002).

The context

The School of Pharmacy at The University of Auckland recruits students from throughout New Zealand. Many students leave Auckland during university breaks, whilst others have work or family commitments to contend with. This year, the 99 students enrolled in P101: Pharmacy Practice I had five weeks to complete the group assignment. Two of these weeks fell in the university break and two were where some students had a heavy academic workload. Therefore, the assignment was re-designed to incorporate an appropriate blend of technologies that allowed students to access and complete this assignment flexibly and removed the need for them to meet face to face with other group members or to visit the campus library in person to search for information. The components of the assignment and respective assessment details are presented and described in the Table 1.

Table 1: Components of P101 assignment

Component and format	Requirements	Assessment details
e-poster (developed using Microsoft PowerPoint template based on an exemplar provided).	Students were randomly assigned into groups and asked to collaboratively design an e-poster on a given topic. In this case, the topic was the social implications of a chronic disease.	Group mark. The assessment rubric covering content, references and overall design was available to every group member.
Oral presentation of the e-poster (free use of props and different presentation tools).	Students, in their respective groups, present their e-poster to the class.	Group mark. The focus of the assessment was on the depth and breadth of research reflected by the quality of the presentation and the group's ability to answer questions from the class.
One page written summary of work (print out).	A referenced summary of the e-poster, representing the group's findings is handed in at the oral presentation session.	Group mark. The focus was on properly crediting and referencing all the literature used in the e-poster.
Three web references with justification for their usefulness (shared electronically).	Individual students are required to share three web references that they found useful in retrieving information for the e-poster. They are encouraged not to duplicate website references already shared by their classmates.	Individual mark. Marks were allocated based on the quality (judged by the criteria discussed in the lecture) of the websites submitted.

Design of an integrated assignment

Learning design considerations

A review of literature on evolving learning designs based on the tenets of Pedagogy 2.0 (Lee & McLoughlin, 2010) highlights four contributing elements of design for socio-constructivist learning environments: authenticity (Alam & McLoughlin, 2010; Cigognini et al., 2010) , motivation (March, 2007), scaffolding (Bates, 2010; Brack & Van Damme, 2010; Collis, 1998; March, 2007; Ryberg et al., 2010; Sthapornnanon et al., 2009) and skills development (Alam & McLoughlin, 2010; Bower et al, 2009; Cigognini et al., 2010; Gunn et al., 2010). It is important to note that all these elements were identified and taken into consideration for our specific learning design as P101 is an introductory course where, for most students, this was the first time they had experienced the educational use of Web 2.0 in their degree programme. Hence, capitalizing on the evidence base, the use of Web 2.0 tools was authentic, purpose driven, well scaffolded and linked to assessment while attempting to develop students' digital literacy and knowledge management skills for life-long learning opportunities.

The aims of the learning design were:

23. To provide flexible access to resources and tools to enable students to complete individual and group components of the assignment off campus.
24. To enable the teacher to monitor student collaborations in group tasks and manage assessment better.
25. To enable students to develop personal knowledge management (PKM) skills in Web 2.0 that they can use in the Bachelor of Pharmacy programme and beyond.

Figure 1 visualizes the learning design concept, which was a combination of approaches suggested by Bower et al. (2009), Dave (2009), McLoughlin & Lee (2010), McLoughlin (2002) and represented in an adaptation of the PKM skills model (Cigognini et al., 2010). Core to our learning design was the idea that 'technology is a mediator of pedagogy and content' (Alexander, 2006 cited in Bower et al., 2009). The types of thinking and processes that students needed to engage in to complete their course requirements was paramount in identifying the appropriate blend of technologies. The position of technology in the periphery of the design is testament to the fact that technology does not drive learning but it does have affordances that can be built on to provide better learning experiences. In addition to this, technologies are rapidly changing hence the broken line. Knowledge and skills are at the core of the learning design. In this case, technology enabled us to provide flexible access to the course content ensuring equity in access and facilitated the development of digital literacy, group culture and PKM skills. The latter was possible through linkages to the course assessment that provided some degree of motivation for students to engage sufficiently.

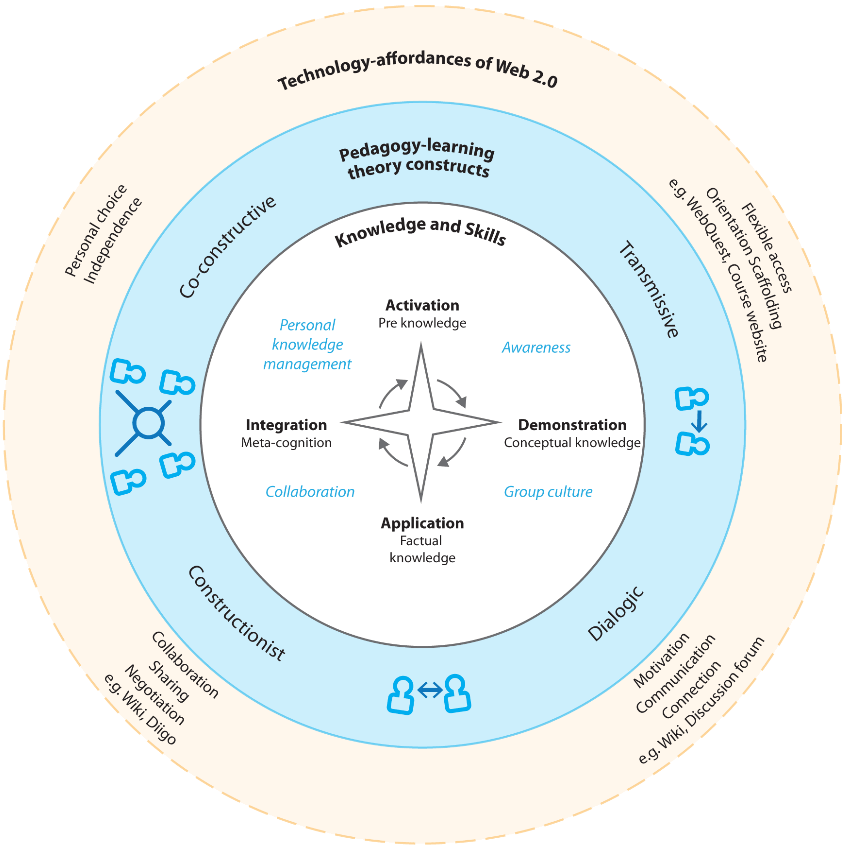

Figure 1: Learning design of P101 integrated assignment

Affordances of Web 2.0

As defined previously, Web 2.0 refers to social software. The myriad of Web 2.0 applications available (see http://www.go2web20.net/) add to the complexity of matching the affordances of each with its usefulness in education. Common applications that have been widely used in educational contexts are blogs, wikis, social bookmarking and social networking. Meaningful use of these tools can vary from mere provision of information (flexible access, orientation) and guiding learning processes (scaffolding) to encouraging motivation, enabling connections and PKM. The particular function is largely dependent on the context in which these tools are used. It is suggested that a 'suite of tools' is better than a particular technology in learning designs to ensure learners have a choice to "engage in meaningful tasks" (Alam & McLoughlin, 2010). The type of tasks and thinking processes students engage in are far more important than the type of technology (Alexander, 2006 cited in Bower et al., 2010). With due consideration to this, we used a number of tools in our learning design as described in Figure 1.

Pedagogy for Web 2.0 learning design

Ways of interacting to engage in knowledge building processes is an important element of online pedagogy (Bower et al., 2009). Web 2.0 learning designs are usually situated in the socio-constructivist approach. However, as educators document their Web 2.0 learning designs, it is becoming obvious that there still is a place for transmissive, dialogic and constructionist approaches. Many students need the 'structure and guidance' (Bates, 2010) that can be offered via the transmissive approach. A particular example from our learning design is the provision of information on the course website including detailed descriptions of each tool and 'how to' guides. Though transmission is considered a low order thinking process, it is still relevant in 'cognitive apprenticeship' (Collins, Brown & Holum, 1991, cited in Bower et al., 2009) where the expert imparts knowledge and models thought processes.

Dialogic and constructionist approaches are centered on discourse between peers in a learning environment that encourages and motivates students to engage in meaningful dialogue; a core requisite for collaborative learning. These can be built on to produce a co-constructive pedagogy where learners are expected to engage in higher order thinking processes and develop the ability to manage information and take control of their learning while sufficiently engaging in collaborative group work. Our learning design, as it was for beginner skills and content, did not aim to proceed to the highest level of PKM.

Knowledge and skills
As mentioned before, Web 2.0 learning designs have increased focus on developing skills such as knowledge management and information literacy to enable learners to take full advantage of these learning environments (Cigognini et al., 2010). According to Cigognini et al. (2010), PKM is a 'multifaceted set of abilities and processes' that an individual undertakes to gain and share knowledge. This hinges on 'digital competency' when the learning environment is Web 2.0 based. Since our design was for an introductory course, every attempt was made to facilitate the development of PKM skills. The development of such skills takes time, however, the process begins in a close structured environment such as that provided in the design of the P101 technology integrated assignment tasks.

Selection of technologies-finding an appropriate blend

Information and structure through the course website
The course website was designed and developed using an in house interactive web development tool called CourseBuilder (http://www.cad.auckland.ac.nz/index.php?p=coursebuilder). It complements the features and capabilities of the Learning Management System, therefore enabling us to make optimal use of both systems. The website provided all the information required to complete the assignment e.g. timetable, deadlines, group allocations and extensive stepwise instructions on how to use the e-tools provided.

Scaffolded inquiry through a WebQuest
The assignment itself was presented as a WebQuest (Dodge, 1997) which contained detailed information to allow successful completion of the assignment. The WebQuest strategy was proposed by Berni Dodge and Tom March in 1995 to develop engaging web-based tasks that elicit higher order thinking through guided inquiry (Starr, 2005). Rather than force-fit an earlier approach, we adapted the revised version of WebQuest that "highlights its benefit to both students and teachers as a framework for leveraging achievement and maximizing authentic learning" in a Web 2.0 world (March, 2007).

In order to create an authentic experience that was contextualized, students, in their randomly assigned groups, were allocated a chronic disease and asked to produce a promotional e-poster for a fictional charity trying to elicit donations from the public. All information presented had to be sourced from the internet and general criteria were set about the scope and format of the e-poster (see Table 1). E-posters were accompanied by an oral presentation to peers, and at the end of the assignment, students voted for the groups that they felt elicited in them a desire to make a monetary donation. Tasks included listening to a recorded lecture, accessing and extracting information from websites providing guidance on team work, and voluntary tasks and quizzes related to searching, retrieving, and appraising medical and health information sourced from the internet. Some educators perceive the inherent structure of the WebQuest to be limiting (Barbour, Rieber, Thomas & Rauscher, 2009) but as indicated by Bates (2010), we wanted to provide a structure and sufficient guidance to motivate students to engage in the learning process. 'Transformation scaffolds' form the core of every WebQuest and can encourage student motivation and facilitate advanced thinking with appropriate integration of enriched learning resources (March, 2007). According to March (2007), technology can provide its 'disintermediating effect' that can help learners prime their own intrinsic motivation.

Collaborative learning through a group wiki
A wiki (PbWiki) was provided for each of the groups, which consisted of four or five randomly allocated students. The use of wikis in socio-constructivist environments involving group work is well documented (Cain & Fox, 2009; Collis, 1998; Miller, Bookstaver & Norris, 2009; Collins, Huber & Groom, 2010; Brack & Van Damme, 2010; Bower et al., 2009) and according to Dabbagh & Reo (2010, p14) wikis "epitomize the social constructivist idea that knowledge derives from social interactions, since it is a social software tool that makes it easy for multiple users to create and edit web pages collaboratively."

The wiki enabled flexible access and multiple options for group collaboration. Though we set up wikis for every group and encouraged them to use this collaborative tool, the onus was on the groups to put this into effective practice as no marks were allocated for using the wiki. The usefulness of such a collaborative technology is dependent on many variables (see results and discussion).

Networking, knowledge construction and sharing through social bookmarking
A social bookmarking site (Diigo) was used for students to submit individual contributions to a shared bank of web resources. The networking nature of this tool enabled students to share their web references and provide feedback on other students' submissions. A requirement of this task was to avoid duplication of references already submitted by other students on the network. This added an element of competition, intended to motivate students to realize the full potential of social bookmarking which according to Bower et al. (2009), can range from the promotion of recall, identification and exchange of factual information to facilitating discourse.

Student perception of learning design for technology integration

All students in this cohort successfully completed the assignment. However, in order to evaluate the learning design for technology integration from the students' perspective, their opinions of the assignment were sought via an anonymous online survey and a focus group facilitated by the lead author. The online survey was adapted from the one published by Burchum et al. (2007). It consisted predominantly of questions presented in a 5 point Likert scale format but also included questions requiring ranking and free text responses. The focus group was intended to gather more considered and detailed opinions on the process of completing the assignment and the perceived usefulness of the technology integration into the assignment. Participation in both activities was voluntary and in order to facilitate the candid opinions of the participating students, the identities of those who participated in the focus group were kept confidential and not revealed to the School of Pharmacy staff member involved in this project.

Results and discussion

Online survey
Fifty four students out of 99 completed the survey; therefore, a response rate of 54.5% was achieved. An encouraging 67% of the responding students enjoyed the assignment. Table 2 provides a summary of the responses in relation to specific strategies and tools used.

Table 2: Summary of evaluation

Strategies and tools	**Students' perception**
Scaffolded inquiry into an authentic task - WebQuest	77.8% agreed that the WebQuest added value to the assignment. 87% thought the WebQuest tasks assisted them in learning to distinguish between reputable/authoritative websites from other less reliable ones. 51.9% agreed that the WebQuest contained enough information to complete the assignment without any further instructions from the teacher.
Collaborative learning - wiki (PbWiki)	Wiki was ranked the most useful and enjoyable and 68.5% would be confident to use them in future assignments. However, 44.4% of students were unsure if the wiki promoted effective student-student collaboration.
Networking, knowledge construction and sharing – social bookmarking (Diigo)	Diigo was voted the least enjoyable but the second most useful of the tools. 48.1% do not intend to keep using and adding to the social bookmarks created during the assignment while 42.6% were undecided.
Knowledge and skills development (digital literacy measured as 'tech savvyness', group work, knowledge management) – use of various etools in assessed tasks	51.9% agreed that the assignment tasks helped them develop transferable technical skills. Figure 2 illustrates the change in 'tech savvyness' before and after completion of the assignment. 75% of students thought that the assignment developed their ability to work effectively in a team and 63.5% thought that their team worked well together. However, free text reponses indicate that managing the group work was also a challenging aspect of the assignment for some students.

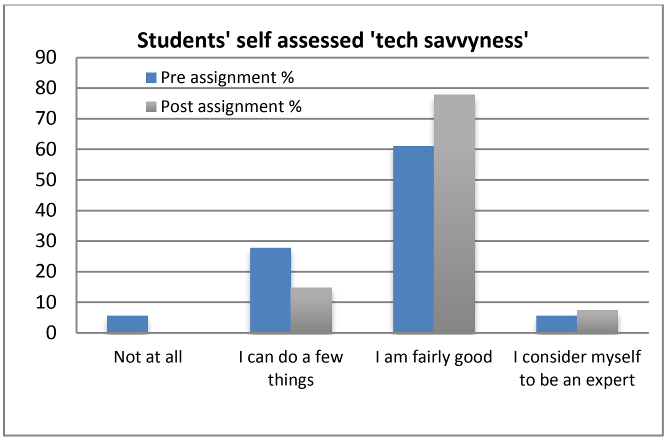

Figure 2: Self assessed student 'tech savvyness'

Focus groups and open ended responses

Focus group responses re-affirmed the findings of the online survey. The assignment as a whole was well received but some students expressed dissatisfaction with aspects of the group work involved. As many groups failed to negotiate roles and get the work done equitably some students thought that it was unfair to award marks predominantly based on group produced work. This is consistent with what Brack & Van Damme (2010) reported as group progression from collaborative to cooperative over the course of the group task.

Motivation was also another important factor with most students complaining about the lack of commitment shown by some group members. The idea of introducing a reward system for those taking the initiative was also suggested so individuals are held accountable for their part in the group task. Two student quotes given below illustrate contrasting views on group work.

> "group work sucks. I ended up doing heaps of ours while others did very little. It just doesn't seem fair. And i know that the idea is to work together, BUT if your members are not responding to email after email after email, then what else are you suppose to do? Fail or do it all. It puts studious students under too much stress and gives slackers a free ride." (P101 student)

> "…thank you for giving us the opportunity to know our team members better! I felt that this assignment was a great way to promote team-bonding!" (P101 student)

It was also clear from student comments in the evaluation that though majority of the assessment tasks required them to collaborate in groups, their individual experiences were quite varied. The perceived usefulness and the extent of use of the Web 2.0 tools were dependent to some degree on students' digital literacy and technical skills. Though attempts were made to facilitate the development of such skills to influence the extent of use, not all the tools were utilized to their maximum potential. The difference in 'tech savvyness' (see Figure 2) is evidenced in the following comments:

> "We only had to use basic programmes for this assignment so I did not really learn anything too extravagantly new." (P101 student)

> "I would definitely use Diigo now as a good bookmarking source rather than adding a whole bunch of websites to my Favourites tab on my browser…" (P101 student)

Contributing elements of design for socio-constructivist learning environments revisited

Authentic learning

The use of a WebQuest enabled students to engage in an authentic learning experience that Cigognini et al. (2010) advocate is the basis for developing digital literacy and knowledge management skills. The graduate profile for the Auckland School of Pharmacy includes the ability to be able to communicate effectively in writing and orally, apply critical thinking and structured problem solving techniques, and utilise technology effectively to acquire, organise and present health-related information. In addition BPharm graduates are expected to be able to work both independently and in teams, both as a leader and a member. Successful completion of the WebQuest to develop the e-poster provided the opportunity for students to develop, apply and demonstrate aspects of all these skills. Boud et al (1999) suggested that students articulating their emerging understanding of an area can deepen their own grasp of the subject. The oral presentations associated with this assignment involved peer teaching and were well received by students, indeed some students suggested making the oral presentations longer to enable them to fully articulate what they had learnt.

Motivation
Collis (1998), Alam & McLoughlin (2010) and Brack & Van Damme (2010) all mention aspects of motivation as influencing the success of group tasks using collaborative tools like wikis. In P101, wikis were provided as a tool to help students collaborate and complete their assignment flexibly but the use of the collaborative wiki was not compulsory. Student satisfaction with using this tool depended on their experience of group work. Frustration arose due to the asynchronous nature of the wiki because motivated team members found that it was difficult to communicate with and manage the contributions of less motivated group members. Though the task was designed to be 'motivating in itself' as Collis (1998) suggested, sufficient engagement from students depended on how their groups utilized the wiki as the onus was on them to be active in the inquiry process (Alam & McLoughlin, 2010).

Facebook groups were set up spontaneously by several student groups, and texting and e-mail was also used as an alternative to the wikis. Students found the use of these methods more effective than the wiki for communication, coordination and management of data collection and assimilation tasks required to create the e-poster. However these alternative methods of completing the assignment did not allow the teacher to monitor individual contributions and group progress in this instance.

Scaffolding
This concept is widely publicized in all aspects of Web 2.0 use in educational contexts as a result of researchers questioning the assumption that 'digital natives' possess sufficient digital skills to learn effectively in technology integrated environments. Sufficient scaffolding through strong links to curricula is suggested by Ryberg et al. (2010) for young people who might not come to university equipped with digital literacies.
As indicated in Table 2, the majority of students found the WebQuest activity to be valuable for their completion of the assignment. This aspect of the assignment was also the most structured with scaffolding being the very justification of its existence (March, 2007).

McLoughlin (2002) presents various categories of scaffolds, of which, orientation (communication of expectations), coaching (learner support via software help), task support, expert regulation (sharing exemplars), conceptual and procedural scaffolding were all implemented in various ways in this integrated assignment. However feedback from the student evaluation indicated that the assignment instructions concentrated predominantly on the e-tools and knowledge required to complete the assignment, which improved the equitable nature of the assignment but neglected to equally scaffold the team work aspects of the assignment. To improve this aspect of the assignment the next iteration of the learning design will incorporate the soft and hard scaffolds of face to face orientation and instructions for group work respectively (Brack & Van Damme, 2010). We intend to cover aspects of team work including roles, work allocation and communication strategies in a workshop and introduce a team building exercise at the start of the assignment. A requirement for group and individual progress reports will also promote accountability and encourage participation of all group members. This will also allow the teacher to monitor and manage any issues that occur and also allow individual student marks to accurately reflect their contribution to the assignment.

Skills development
Perhaps the best indication of students' developing knowledge management skills was the use of the social bookmarking tool (Diigo). The individual task involving Diigo, was worth a small percentage of the marks available for this assignment, and was completed by almost all of the class (98%). However evaluation of the assignment revealed that whilst some students used the class Diigo resource bank extensively to find material for their poster slides, some students did not realise the full potential of social bookmarking and used Diigo only to upload their websites to be eligible for their marks, without participating in and benefitting from the social aspect of this tool. In the next iteration of the assignment more time will be spent encouraging students to use this tool to its full potential by explaining the benefits of using this tool both for the assignment and throughout their degree programme and professional lives. Penalties for posting a web page already submitted will also be imposed. This will require a greater degree of engagement on the part of the student and may change their current perception that clearly indicates superficial level of engagement.

"Social bookmarking was done only because it was compulsory. It could have helped me if I was

> trying to collect as much information as possible but my aim was to complete the assignment, and therefore researched only information I needed…" (P101 student)

As mentioned before, PKM skills take time to develop and it may be that students need more exposure to the use of social bookmarking to fully appreciate its relevance and usefulness.

Design plans for future iteration

In addition to what has already been mentioned, the next iteration of the course will focus on facilitating effective group work and promoting student engagement with the aspects of Web 2.0 tools that were underutilized this time. Perhaps a social networking tool such as Facebook may be used for collaborative work based on its communication features. As reported by Dabbagh & Reo (2010), there are three levels of social software use: level 1 is personal information management, level 2 is basic interaction and sharing and level 3 is social networking. The use of wikis and social bookmarking by P101 students in this assignment did not progress to the highest level of networking, as envisaged in the learning design but this might improve with the use of an actual social-networking tool for the purpose of collaboration.

Estus (2010) demonstrated the positive impact of using Facebook in an academic context with American pharmacy students. Creating private Facebook groups which all groups are required to use would enable the group work aspect of this assignment to be monitored and is an avenue that we intend to explore in future. We believe that the minimal use of the tools may have been because of the students' lack of appreciation of the potential and possibilities around knowledge management enabled by these tools, in particular, collaborative learning.

Conclusion

This paper details an innovative learning design for the integration of technology to achieve flexibility in access and encourage engagement while facilitating the development of knowledge management skills in an introductory pharmacy course assignment. The results of the evaluation of the first iteration of the design are encouraging. All students successfully completed the assignment and some did develop skills as evidenced by the change in 'tech savvyness'. However, the intentions of the design did not fully eventuate in student actions for active development of PKM skills. The lessons learnt from the first iteration will be used to inform the learning design of future iterations.

Database of Research on Distance Education

Lance Deveson
Library & Information Manager
Australian Council for Educational Research

The Distance Education Research Database is an invaluable resource for anyone with a stake in the distance and online education industry. It will keep you up to date with the latest thinking in distance and online education around the world, allow you to examine a treasure trove of research relevant to your professional development and provide a solid basis for your future studies. The Poster session will demonstrate the database , its features and practical uses.

Keywords: Higher Education, International Students, Transnational Education, Distance Education, Blended Learning, Online Education

Database of Research on Distance Education

The Distance Education Research Database is an invaluable resource for anyone with a stake in the distance and online education industry. The DEHub research database contains details of over 7200 books, articles, conference papers and reports on various aspects of distance education and distance learning from publishers in Australia and overseas. Material in the database is drawn from the Australian Education Index, produced by Cunningham Library at ACER, with additional material sourced from a variety of international organisations and publishers

The database is managed by the Australian Council for Educational Research (ACER) for the Distance Education Hub, a research consortium between the University of New England (UNE), Charles Sturt University (CSU), Central Queensland University (CQUniversity), the University of Southern Queensland (USQ) and Massey University.

The database is available via the DEHub website: http://www.dehub.edu.au/

Database features

- Relevance – all articles related to distance or online education
- Currency of information – 20% of articles published in last 3 years and database is updated monthly
- Accuracy – articles selected and indexed by qualified librarians

- Searchable by keyword, title, subject, author, organisation, date or country
- Useful links to over 30 journals and newsletters on distance or online education
- Links to relevant organisations, publishers and websites
- Free access via the DEHub website

Journals indexed in the Database include

Embedding an ePortfolio system at a programmatic level

Stuart Dinmore, Ben Kehrwald & George Bradford
Learning and Teaching Unit – University of South Australia

This paper outlines the ePortfolio implementation process at the University of South Australia. The eP system, powered by the open-source ePortfolio Mahara, is one element of an integrated suite of technology enhanced tools for teaching and learning at the University and will be available to all students and staff from the second half of 2011. This ePortfolio system has been chosen because of its flexibility and its capacity to be the venue for many complex tasks.

We have sought to conduct the implementation of the eP, for teaching and learning purposes, at a programmatic level across the institution. We recognise that for a system like this to operate optimally it needs to be integrated within a program of study at every year level and that piecemeal approaches to using ePortfolios, while of some value, do not ultimately allow the full potential of portfolio learning styles to flourish. This paper reports on the work-in-progress of our ePortfolio implementation.

Keywords: ePortfolio, programmatic implementation, learnonline, Mahara, academic development.

learn**online**

After an extensive examination and feasibility process, featuring a great deal of commitment from and collaboration between, the various stakeholders within the institution, it was decided in 2010 that the University of South Australia would adopt Mahara, the open-source ePortfolio. This system is currently being rolled out institution-wide and will be available to all students and staff during the second half of 2011. The University's Learning and Teaching Unit is entrusted with the effective implementation of the software, for the use of academic staff, across the institution and this paper will outline some of the academic development processes for embedding the eP across the divisions of the University.

The University's, fully integrated, learn**online** system includes a Learning Management System, a virtual classroom, a lecture recording system and an ePortfolio. All of these elements are being introduced over a two year period. This paper will discuss one facet of the current implementation process and that is the embedding of the ePortfolio (eP) at a programmatic level. Thus this paper is a case study of the early planning and implementation process as we look to roll-out eP's across entire programs of study. We are a large university with four divisions and there is intense interest from among our staff for an eportfolio.

Before a discussion of the training and development profile we are adopting it's useful to outline the main ideas underpinning our approach to the design and implementation process. The key elements of which are:

1. A recognition, as noted in the supplementary report of the Australian ePortfolio Project (Hallam et al, 2010), that 'the extent of ePortfolio (eP) practice has moved away from their use mainly in single units of study towards more programmatic implementation in undergraduate student learning'. We recognise and strongly recommend that for an eP to be most effective, a whole-of-program approach is desirable.

2. That based on the conclusions of Clark and Neumann's (2009) study on ePortfolio implementation which stated that, 'use of these ePortfolio tools to support teaching, learning and professional development is complex and requires considered pedagogical planning and preparation if they are to be usefully appropriated' our approach is extremely thorough and preparation needs to be completed well prior to the commencement of the program.

3. That we strongly encourage the development of a consultative and collaborative environment to work in, the importance of which is highlighted by Gathercoal et al (2002) and Lambert and Corrin (2007), in their discussions of ePortfolio implementation.

4. That during the program mapping, development and design phases of the process, a strong rationale for the use of an eP is developed in accordance with the stated aims of the courses involved and the program within which they operate. As Stefani, Mason and Pegler (2007, p. 45) point out, 'the overarching issue is the pedagogical principles underpinning the rationale for implementing ePortfolios in to the curriculum'.

5. That, where possible, the implementation be part of a broader impetus around the integration or development of technology enhanced learning and that this aim is commensurate with financial support from the institution for the program who undertakes the implementation. This kind of support helps with the issue of academic staff buy-in and the workload pressure that development work like this can bring.

These five elements form the basis for our approach to the implementation process, a process which begins with academic staff involved completing six hours of basic technical training. This includes four hours of computer lab based instruction and two hours of self-study. At the completion of this all staff in a particular program will have a working ePortfolio of their own, including their individual profile, membership of various groups/networks related to their program and a working knowledge of how to create and disseminate various fully functioning views/pages. These artefacts can contain a wide range of multimedia (both embedded and externally sourced) and elements like blogs/journals, forums and the creation of forms for recording professional competencies. They will then move through a four month period of development working closely with academic developers to design, develop and implement materials to support their courses. These materials will become part of academics' individual ePortfolios but they are also able to use them as artefacts to scaffold future course development should they choose.

Before the mapping, design and construction phases of the implementation could commence, an ePortfolio implementation pack was created to be used throughout the entire implementation process. This toolkit enables academic developers to work with academic staff from any given program in a coherent way and ensures that there is some consistency around the development of rationales for eP usage. The tool kit contains a blank program template, which is essentially a spreadsheet in to which every course from a program can be added and its elements examined and compared. It also includes a pre-populated template, or matrix, by way of an exemplar. There is also a grid of eP pedagogies aligned with tasks and desired outcomes, a short paper outlining the basis of our approach and a list of criteria for both course and program level implementation. These tools are a key element in the development of a rationale for implementation and lead to a familiarisation and alignment with eP pedagogies for the academic staff involved from the outset.

The tool kit also contains a series of proforma exemplars outlining the various pedagogical possibilities with eP use to be used during the eportfolio design phase of the implementation. This involved the development of specific materials for the purpose of each broad assessment type. The artefacts created for this objective contain the following exemplars and are embedded as copyable views within our ePortfolio system – reflective practice – presentation of evidence – professional competencies – mobile content – using multimedia – self and peer review – group work/collaboration – eP's and WEB 2.0. This allows them to be easily accessed and disseminated among academic teaching staff and can help to provide guidance for teaching staff that choose to use the eportfolio system without undergoing training or a systematic ePortfolio implementation:

Table 1: Phases of the four month ePortfolio implementation process

Confirmation of course elements. *1. Course and staffing details* *2. Assessment details* *3. Professional Competencies* *4. Rationale for implementation*	Course structures (including assessment and course outcomes) will be designed to incorporate eP's and these designs will be aligned with factors established in the mapping phase.		Individual course groups will develop materials/resource/artefacts to be implemented in their courses in the following study period.	Materials and processes developed in the previous phases will be implemented into course and program structures in readiness for upcoming study periods.	
Familiarisation and alignment with eP pedagogical possibilities.	Begin development of ePortfolio communication strategy for students of particular program.		Begin to generate and validate the learning resources.	There will be a comprehensive peer and self-assessment period at the conclusion of this phase with the wider program team with analysis of both the process and the implementation itself.	
Using list of criteria, courses will be assessed for suitability for eP implementation.					

Program Mapping

Program mapping is the evaluation of the selected program to ascertain appropriate courses for an eP implementation. The goal of the process is to create a map/matrix of potential eP usage throughout a program. Before the process of program mapping can begin a sufficient level of consultation with key stakeholders (program directors, course co-ordinators and all program teaching staff) must occur. During this period it is essential to for academic staff to share documentation about the structure of their particular program, and plans for development or alteration in coming years. This should include information about assessment, course outcomes and graduate qualities. This allows for the program template to be partially populated prior to the start of the mapping sessions.

The time commitments for this phase of the process are (2-4 hours for the program team, including those who may not be involved in ongoing development) and 3 hours per person, plus academic developer and program director liaison. This process promotes a shared understanding and ownership of eP development and gives a holistic view of how an eP will be a fully integrated part of both a staff members and student's experience. This process is also an essential part of building the overall justification for a student to use an eP in the first place. Academic staff will need to communicate the potential benefits for students throughout the course of their program, whether they are used for assessed or non-assessed activities, for professional networking or interprofessional communication. Indeed, student awareness of career planning, which generally takes place outside the domain of the course structure but is an essential element of a student's overall experiences can be a crucial element in eP adoption. As McCowan, Harper and Hauville (2005) noted in their discussion of the eP implementation at QUT, 'when the career-related benefits were discussed and its role as an organising and selection preparation tool were understood, students adopted it wholeheartedly'.

In this mapping phase courses are added to the template by way of a grid that separates the study periods. To this are added the following aspects of each course:
• Course and staffing details
• Assessment details
• Professional competencies (if applicable)
• Rationale for implementation

Individual courses are then assessed by program academic staff and academic developers using the following criteria. The teams analyse whether in courses;
- students work with rich media
- there are professional competencies associated with credentialing
- students generate artefacts regularly
- reflective practice is a feature of student activity
- there are practical components to the program which can be supported with eP use
- the course has a career planning focus
- the course is part of a series that develops over the three or four year course of a program
- has group work
- requires students to organise activities autonomously
- there is already an eP element to other courses within any given study period

When all the above factors are taken in to consideration a rationale for implementation or not is developed and the template generates a complete list of courses that will use eP including their assessment profiles, desired course outcomes and the teaching staff involved. Results from the early stages of program mapping indicate that between 40-50% of courses actually decide to implement the eP.

Course and ePortfolio Design

The list of courses is then used to organise a training schedule for specific groups of staff and to eliminate others. The groups become course based and academic development begins with small groups of staff to begin the design phase of the process. The rationales developed for the implementation in the program mapping phase are now used to inform the initial design process. In conjunction with the ePortfolio exemplars mentioned above these rationales are used as a foundation to design course/ program specific resources. Thus it is essential that course structures be designed to incorporate eP's and that these designs be aligned with reasoning established in the program mapping phase.

The time commitment for academic developers and course teams to do design and development work requires 1 hour meetings held fortnightly and this means that staff would commit 8-10 hours per person. This involves a 50/50 split between consultation/discussion/planning with an academic developer which could be considered situated work to link program plans to individual course planning, staff development, materials design and development and private study. This time will be used for working our processes for use of ePs associated with particular learning activities and/or assessment pieces. The course designs are stored in the eP as work-in-progress artefacts, thus there will necessarily be some overlap with the following resource and content creation phase, where the artefacts become fully realised. When all the individual course teams have their designs for implementation completed, the final phase of this section of the process is a peer review session involving the entire program team, including program directors and all relevant teaching staff.

Resource and Content Construction

Based on the work done in the design phase and on the feedback received during the peer review phase the academic staff now begin the 'hands on' work of materials development: writing, creating eP artefacts and views. The goal of this phase will be to have completed the construction of their materials and support resources for the following study period.

This phase is will consist of individual/small group work on development estimated to take 10-25 hours of individual work, depending on how course teams divide the labour. It is estimated that roughly 20 hours individual work per person will be required. The figure will decrease for larger course teams who can divide the labour between them and individuals who are involved in development for multiple courses as they will learn from experience and work more quickly or staff who have experience with ePortfolios. It will increase for staff who teach individually (bearing the entire development load for a course), have specialised uses of the system in mind which require extra development time or need extra support. The time will vary according to the degree of integration (e.g. one or two tasks vs. several ePortfolio tasks) within a course and the extent to which staff are experienced with the technology.

Implementation

In the final phase, materials developed in the previous phases will be implemented in to course and program structures in readiness for upcoming study periods. A crucial element of this phase is the completion of a coordinated communication strategy across the program to ensure student awareness of the eP system and an integrated help resource on the University's website. Courses that have implemented the eP will continue this process at the commencement of the next period with the aims of the strategy being built in to course structures and course help resources. Once the materials and artefacts have been created and embedded in the eP system there will be an evaluation of both the process and the resources created by the process. At the end of every programmatic implementation there will be a coordinated period of self and peer assessment undertaken within the eP system itself and a focus group with academic staff. Staff will also provide feedback on the process and an evaluation of the design effectiveness using a customised survey instrument.

Conclusion

The ultimate goal of this process of staff development and programmatic implementation is that it becomes integrated with the academic development of all the other elements of the learn**online** project to achieve a focussed, cohesive whole. This approach will help leverage our integrated systems to promote deep learning and improvements in teaching and learning for all staff and students across our institution.

Learning new technology tools in pre-service teacher education: A model for instructional approach

Shanti Divaharan
Nanyang Technological University,
Singapore

The purpose of this qualitative study is to propose a model of instructional approach for pre-service teacher education in the area of learning a new technology tool. Through the instructional approach, it is hoped that pre-service teachers will become confident in integrating the technology tool which they have learnt, to enhance teaching and learning in the classroom. The study involved 30 Post-Graduate Diploma in Education (Physical Education) pre-service teachers and 59 Post-Graduate Diploma in Education (Secondary) pre-service teachers who were attending a core Information and Communication Technology (ICT) course in the year 2010. An instructional approach was designed for the implementation of video sports games for the 30 Physical Education (PE) pre-service teachers and for the implementation of Interactive White Board (IWB) for the 59 Post-Graduate Diploma in Education (Secondary) (PGDE Sec) pre-service teachers. During the course, the pre-service teachers were introduced to Video Sports Games and Interactive White Boards through an instructional approach that comprised of self-paced team exploration of the tools, peer sharing and critique, team exploration of various lesson plans culminating in lesson ideas/plans designed as a team. Based on data collected through observations, reflections and artifacts submitted by the teams, this study proposes a refined instructional approach to be adopted at the pre-service teacher education level for effective learning of the technology tool. The findings revealed that immersion time with the tool, team learning, peer sharing and critique were significant components which enhanced the pre-service teachers' learning experience. The study explores the significant role of the tutor and pre-service teachers and proposes an enhancement of the current instructional approach.

Keywords: Teacher Education, learning technology tool, instructional approach

Background

A number of studies have reported that the large amount of investment in technology integration in education did not reap the desired results. Concerns were raised that the potential for ICT to change how teachers teach and how students learn had not been fully realized (Bate, 2010; Meredyth, Russell, Blackwood, Thomas, & Wise, 1999). Other studies reported that although technology integration has taken place, teachers were not making effective use of ICT for teaching purposes (OECD, 2001; Venezky & Davis, 2002; Voogt, 2008; Wray, 2009; Zhao & Cziko, 2001,).

The intention of this qualitative study is to propose a model of instructional approach for pre-service teacher education in the area of learning a new technology tool. Through the instructional approach, it is hoped that pre-service teachers will become confident in integrating the technology tool which they have learnt, to enhance teaching and learning in the classroom.

Research on teacher learning of technology tools

One of the key factors that had a considerable influence on the teachers' decision to integrate technology was availability of time. Dias (1999) identified lack of time as a barrier to integration. Time in the study encompassed the opportunity to learn, to plan and to collaborate with other teachers. Lack of time was also cited by Wang and Chan (1995) who conducted a study among 130 Singapore secondary school teachers. The findings revealed that teachers' perception of lack of time hindered technology integration. Ertmer (1999) and Manternach-Wigans (1999) also claimed that teachers' perception of lack of time for them to learn and integrate technology into the classroom is a contributing factor that inhibited technology integration.

Dawson and Heinecke (2004) reiterated that teachers' lack of time to explore technology use and fragmented schedules in school contribute to technology being integrated as an add-on tool. The data collected for this study spanned over a seven month period with over eighty hours of classroom observations and interviews with key personnel and teachers in the school as well as document analysis. The explanation given by teachers in the study was that they did not have time to plan for effective technology-based lessons and that they needed time to fit technology in their lessons. In addition, the teachers felt that they did not have time to immerse in the use of the technology to enable them to have the knowledge and technology skills to plan.

Jaber and Moore (1999) and Martin (2000) indicated in their findings that teachers need to be given time to plan and to integrate technology into the curriculum in order to achieve substantial effective integration. Further, teachers should be given time to plan and implement within the school year and to share their successes and obstacles with their peers so as to learn from each other (Wetzel, 2001).

From the findings presented by the different studies, it can be inferred that the teachers wanted time to immerse themselves in technology use so that they would be competent and comfortable users of technology. In addition, teachers wanted time set aside for them to plan and reflect on technology integrated lessons. The teachers also wanted time set aside for sharing of technology resources and strategies. They wanted time to collaborate with each other and to attend relevant professional development that would provide them with knowledge of appropriate technology integration strategies.

Professional Development

Teachers were seen rooted in the traditional instructional form and hence they were not making the necessary effort to integrate technology to create innovative learning experiences for their students (Demetriadis et al., 2003). It is difficult to integrate technology into the traditional classroom practices and hence technology integration has been relatively ineffective (Jules Van Belle & Soetaert, 2001). Results of some studies showed that teachers were not making effective use of technology in their lessons (OECD, 2001; Pedretti, Mayer-Smith, & Woodrow, 1999; Zhao & Cziko, 2001). Some reasons for the dissatisfying results of technology integration could be attributed to teachers' attitude towards computer use (Demetriadis et al., 2003) as well as improper instructional reforms based on improper pedagogical beliefs (Selwyn, Dawes, & Mercer, 2001). Teachers needed knowledge of appropriate technology integration strategies and ICT skills to effectively integrate technology into their lessons to optimize the benefits for their students' learning (Pierson, 2001; Shuldman, 2004). Teachers' professional development needs to focus on both technology skills training as well as appropriate technology integration strategies in the curriculum. Braak (2001) suggested that to overcome the lack of translation of technology competency and comfort level into strategies for applying technology effectively, there was a need to expose teachers to good practices during in-service training. The focus of these training should be to get teachers familiarized with technology, on the use of technology as well as the value of technology as a pedagogical tool.

Some studies reported that effective use of computers is dependent on the teachers' technology skills as well as their intention of technology use (Albalat & Tarrago, 1995; Hodgson, 1995; Venezky, 2004). Relevant professional development can take the form of observing colleagues, learning from each other, observation of each others' technology integrated lessons, as well as to provide opportunities for teachers to share and collaborate with each other (Blase & Blase, 1999; Flanagan & Jacobsen, 2003; Jacobsen, 2001, 2002; Prain & Hand, 2003). Divaharan and Lim (2010) suggest that teachers' technology integration practices can be improved through exchanges among colleagues, attending conferences as well as observing each others classroom practices. Teachers need knowledge of appropriate technology integration strategies and technology skills to integrate technology in ways that optimize the benefits for their students' learning (Pierson, 2001; Shuldman, 2004; Divaharan & Lim, 2010). Teachers' professional development needs to focus on both technology skills training as well as appropriate technology integration strategies in the curriculum.

In précis, it can be deduced from the findings presented from the literature review that there are some key factors that influence teachers learning of a new technology tool and to translate that learning into planning for effective lessons. These factors identified are availability of time, access and relevant professional development.

Most of these studies have focused on the professional development of in-service teachers. There is a need to examine how pre-service teachers' learning should be designed so that they know how to effectively design technology integrated lessons for their students. Pre-service teachers are relatively unfamiliar with teaching practices. The methods for teaching them about pedagogical uses of the technology tools could differ from that for in-service teachers. There is substantial evidence that faculty modelling of technology use is a particularly successful strategy for pre-service teachers' technology integration training (Divaharan & Koh, 2010; Strudler & Wetzel, 1999; Beyerbach, Walsh & Vannatta, 2001; Pope, Hare and Howard, 2002; Brush, Glazewiski, Rutowiski, Berg, Stromfors, Stock and Stutton, 2003). Handler (1993) found that those who frequently saw computers being used in their pre-service methods course felt better-prepared to use the computer as an instructional tool. When tutor modelling is followed by opportunities for them to practice and apply technology tools in the design of lessons, it increased their self-reported confidence level for utilizing these technologies in the classroom (Pope et al., 2002).

A comparison of both in-service and pre-service professional development methods reveals that the technical skills need to be addressed. During in-service teacher professional development, exposing teachers to possible pedagogical approaches seems to enable them to plan and conduct effective technology integrated lessons. In pre-service training, however, there seems to be a need to adopt tutor modelling of the tool so as to allow for pre-service teachers to experience the tool before they are comfortable with designing technology integrated lessons.

The research questions that governed the study are:

1. What are the factors that facilitate pre-service teachers to learn a new technology tool?
2. How pre-service teachers learn a new technology tool introduced in the course?
3. What instructional approach should be adopted to facilitate the learning of a new technology tool for pre-service teachers?

Method

Course context

The study was conducted with 30 PGDE (PE) pre-service teachers and 59 PGDE (Sec) pre-service teachers who were attending a 12-week core ICT course. This ICT course is a core module that trains them in pedagogical skills associated with technology integration in their subject area. Pre-service teachers were taught the theories and principles of technology integration during the first four weeks. The next eight weeks were devoted to the learning of specific technology tools which focused on the pedagogical use of these tools. As tutorial groups were formed by subject specialization, tutors and pre-service teachers in each tutorial group jointly selected two to three specific technology tools that were pertinent to the group. Examples of specific technology tools available for selection were the Interactive White Board (IWB), concept mapping, video sports games, webquests, and Web 2.0 tools such as wikis and blogs. This study was conducted across a four week period where pre-service teachers were learning how to use Video Sports Games and IWB. The learning of each specific technology tool spanned across four two-hour lessons, once a week.

This study was conducted during the July 2010 semester where video sports games and IWB tools were formally introduced after they were piloted in the previous semester. Data was collected from three tutorial groups. One tutorial group consisted of pre-service teachers from PGDE (PE) who opted to learn how to integrate video sports games in their physical education lessons. The other two tutorial groups consisted of 59 PGDE (Sec) pre-service teachers who were from the Humanities and English Language programme. The pre-service teachers are all graduates in the age range of 21-25. They have at least a minimum of two months to a maximum of one year of school experience. This experience helps them to understand the demands of teaching in the classroom with an ICT tool.

The structure of learning specific technology tools

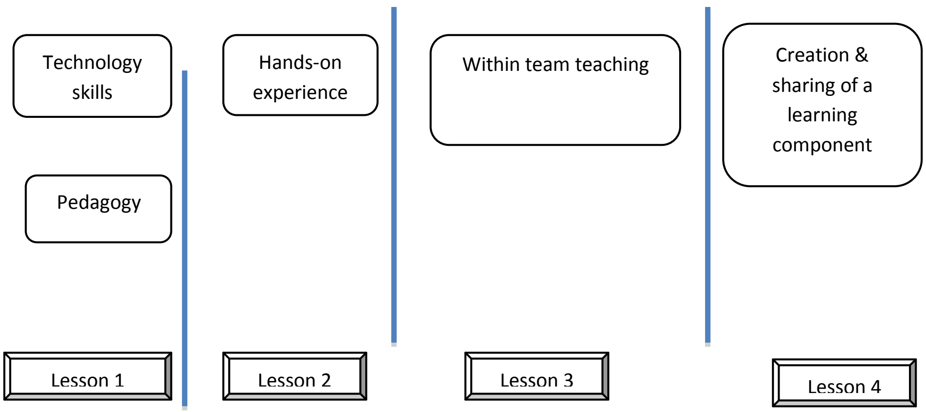

Figure 1: Instructional approach to the specific technology tool component

The approach to the learning of the specific technology tool component was designed based on review of literature (see Figure 1).

Lesson 1 – Self-paced learning from technological resources and pedagogical examples

During Lesson 1, the tutor introduced the various tools to the pre-service teachers. For IWB, the pre-service teachers accessed an on-line self-paced tutorial which helped them to understand how to operate the hardware as well as to learn the key features of the software that accompanied the board. For video sports games, the pre-service teachers explored the various game titles. To learn the technical skills, the pre-service teachers activated the help feature within the software and the game tutorials to assist them in the technical skills.

For pedagogical examples related to IWB, the pre-service teachers were asked to explore a database of lesson templates and materials prepared by teachers from Canada, United Kingdom and America, due to a lack of Singapore based resources. It was hoped that the exploration would create pedagogical awareness of the use of the tool. However, there was a lack of readily available pedagogical resources for Video Sports Games. The tutor created lesson ideas to ground the pre-service teachers' pedagogical awareness.

Lessons 2 & 3 – Hands-on exploration and peer sharing

The focus of lessons 2 and 3 were to provide pre-service teachers opportunities to learn the tool as a team. The pre-service teachers formed teams based on their subject areas. They explored the features of the tools, recalling the self-paced video tutorials as well as online resources. They learnt as a team and taught each other within their teams.

Lesson 4 – Integration of the technology tool in the subject area

After learning the technical skills and acquiring pedagogical awareness of how the tools can be used, pre-service teachers were required to integrate the technology tool in their subject specialization. Each team was required to select an area from their subject specialization and to integrate the technology tool which they have learnt. They were required to showcase how the tool can be used to enhance learning. The focus of this session was to provide opportunities for the pre-service teachers to apply their pedagogical knowledge and to design a lesson segment with the integration of the technology tool.

Data collection

The objective of this pre-service ICT course is to ensure that the pre-service teachers learn a technology tool and acquire pedagogical skills related to integrating the technology tool. Hence, the data collection focused on how the pre-service teachers perceived the learning opportunities provided for them and to refine the instructional approach based on their feedback. To comprehend the learning process, pre-service teachers were given 20 minutes at the end of each lesson to reflect as a team. The PGDE (PE) group had six teams consisting of five members in each team. The PGDE (Sec) group had a total of 12 teams from the two groups. Hence, data was collected from a total of 18 teams with a total of 89 pre-service teachers. Each team posted their reflections on their Wiki page that was set-up for them before the beginning of the module. A total of three cycles of reflection/feedback were collected from each team.

During the Cycle 1 reflection, the pre-service teachers were asked the following questions:

1. How did you and your team members learn the technology tool? Describe your individual experiences.
2. What difficulties did you face when learning the technology tool?
3. How did you overcome the difficulties?

During Cycle 2 reflection, the questions focused on the following areas:

1. What were the strengths and weaknesses of learning as a team?
2. Suggest ways in which the learning process could be improved.

During the Cycle 3, the questions sought to collect information about whether the pre-service teachers felt that they have had sufficient exposure to pedagogical approaches and were able to integrate the technology tool.

1. How did you explore the integration ideas prior to designing the integration of the technology tool?
2. Suggest ways in which improvements could be made in the area of pedagogical awareness.

In the duration of the three lessons for each technology tool, the author who was also the tutor took observation notes on how the groups interacted and their learning preferences. The observation notes and the pre-service teachers' reflections provided useful data as the reflections allowed the researchers to ascertain whether the current instructional approach adopted (as reflected in Figure 1) was effective.

Data analysis

The pre-service teachers' reflections were analysed through the use of content analysis. The reflections were coded in the following manner to answer the research questions of this study:

1. What are the factors that facilitated pre-service teachers learning a new technology tool?

   Responses coded were from Cycle 1 reflection questions 1, 2 & 3 and Cycle 2 Question 2 and Cycle 3 Question 2.

2. How pre-service teachers learn a new technology tool introduced in the course?

   Responses coded were from Cycle 2 & 3 reflection questions.

The pre-service teachers' responses were triangulated with the observation notes by the author.

Results and discussion

Through content analysis, the following factors were elicited from the pre-service teachers' reflections.

Research Question 1: What are the factors that facilitated pre-service teachers' learning of a new technology tool?

Description	No. of teams	% of teams
Time to explore	17	94%
Access to resources	16	88%
Team learning	18	100%
Online tutorials	8	44%
Individual exploration	5	27%
Hands-on exploration	18	100%

Table 1: Factors pre-service teachers felt assisted them in the learning of a new technology tool

Pre-service teachers' reflections showed that they preferred exploring in teams rather than as individuals. They appreciated the time given to them to explore the technology tools in teams. In their suggestions for improvements, they highlighted that they wanted to be comfortable with the technical skills, before they could comfortably explore the possible pedagogical approaches when planning for the integration of the technology tool. Besides, they wanted more time to discuss with their team members and even more time for hands-on exploration.

Research Question 2: How pre-service teachers learn a new technology tool introduced in the course?

83% of the teams (n=15) responded that they wanted to be comfortable with the technical skills first before they could begin exploring the pedagogical approaches to integrating the technology tool. All the teams (100%, n=18) also strongly felt that the culture of sharing among the team members contributed to their confidence in attempting to explore the tool. The fact that they had a common goal – that is to implement the technology tool in their subject area provided the impetus for the pre-service teachers to help each other to learn the tool and to discuss the possibilities for integration in their subject areas. In their comments for improvements, the some teams highlighted that the learning of the technical skills and exposure to pedagogical skills should be available to them at all times (as reference materials). This will allow them to refer back to the resources, should they have any difficulties. In addition, most of the teams (88%, n=16) also suggested that there should be sharing of technical skills, pedagogical skills and lesson integration ideas among the teams so as to enrich their learning from through the sharing by their peers.

Analysis of the tutor's observation notes concur with the pre-service teachers' suggestion. The teams did not attempt to stretch themselves beyond their group capacity. A possible reason could be that they are unaware that there is more potential to the technology tool than what has been explored by the team. One of the best possible ways to scale up their skill levels and knowledge levels may be to make provisions for sharing. This will enable them to be exposed to much more ideas than they have explored within their team. The tutor observation also revealed that there was less apprehension to learning the tool and the culture of sharing and team exploration seem to have provided the impetus to examine an entirely new technology tool which might not have been the situation should the pre-service teachers be required to explore individually. Only about 27% (n=5) of the teams indicated individual exploration as factor that contributed to the learning of a new technology tool.

Research Question 3: What instructional approach should be adopted to facilitate the learning of a new technology tool for pre-service teachers?

Based on the content analysis of the pre-service teachers' reflections and tutor observation notes, the author is proposing a new instructional approach.

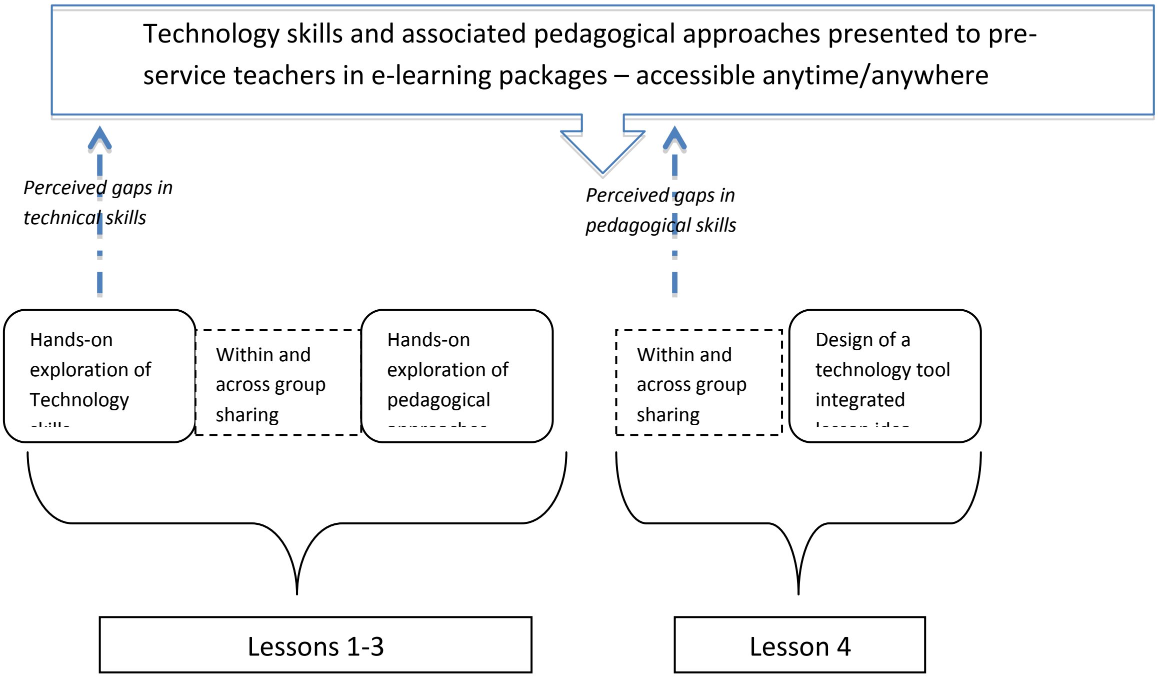

Figure 2: Proposed new instructional approach to the learning of a new technology tool

Proposed new instructional approach to learning a new technology tool

E-learning packages

The proposed design and creation of e-learning packages consisting of technology skills and pedagogical approaches is to provide opportunities for pre-service teachers to learn at their own pace. Based on the pre-service teachers' suggestions, these materials will be made available to them at the beginning of the technology tool learning sessions. The availability of the packages at the beginning of the module makes provision for the pre-service teachers to go through the packages as many times as they need to build up their technology and pedagogical skills. This creates time during face-to-face tutorial interaction. This allows them to make use of the time to discuss, share and learn from each other instead of using tutorial time to learn the technology and pedagogical skills. Hence, when pre-service teachers meet during lessons 1-3, they would have learnt the technology skills and pedagogical skills on their own time. They will come together as a team to share what they have learnt on their own. During the sharing, they can assist each other and to learn from each other. The availability of the reference materials at their disposal, allows for independent and self-directed learning. The anytime/anywhere accessibility to the e-learning packages again makes provision for the pre-service teachers to go back to segments of the package which they feel they need to in order to improve their technology as well as pedagogical skills.

During Lesson 4, the teams will share across, thus making provisions for across team sharing to optimise their learning capacity of the tool. Having learnt the various possibilities of the technology tool and various integration ideas, teams are now ready to design a lesson idea integrating the technology tool. The creation of the e-learning packages provides more hands-on team exploration time, team learning and across team sharing during face-to-face tutorial time.

Focus on learning of technology skills

Feedback from pre-service teachers reiterated the findings from literature that teachers need to be comfortable with the technology skills before they can consider designing and integrating the tool into a lesson. Hence, the technology learning component begins with provisions for mastering the technology skills first in Lesson 1. Time has been given for them to share with each other as well as to share across teams. Once they are comfortable with the technology skills, they proceed to the next stage of exploration, pedagogical approaches. Again, time has been given for pre-service teachers to share their pedagogical knowledge with each other as well as across teams before they are required to design a lesson segment integrating the technology tool that they had explored. By the design stage, this new approach would have given pre-service teachers ample opportunities to gain technology and pedagogical knowledge so that they can comfortably design a lesson segment. Since the pre-service teachers found sharing with peers and learning from other teams extremely useful, the researchers will create more opportunities for them to share, thereby creating a culture of sharing.

Conclusion

The focus of this study was to explore the effectiveness of an instructional approach introduced to pre-service teachers in an ICT core module. The design of the initial approach was refined based on feedback and observation data collected from the pre-service teachers. The crucial modifications made to the instructional approach was to make provisions for more hands-on exploration time, face-to-face team learning and team teaching which was complemented by e-learning packages which can be accessed anytime and anywhere by the pre-service teachers. In addition, as requested by the pre-service teachers in their suggestions for improvement, opportunities have been provided for them to share across teams so that their learning experience is far more enriched. It is not the technology that matters in the classroom; it is the teachers who conceptualise and design lessons to enhance the students' learning experience (Davis, 2008; Taber, 2003; Wood & Ashfield, 2008). Hence, how the teachers learn should be the focus of subsequent research. This new approach will be implemented in the coming semester and the author hopes to collect data to validate the new approach or to refine it further.

Locating Technology Innovation within the Scholarship of Teaching

Iain Doherty
Learning Technology Unit, Faculty of Medical and Health Sciences
University of Auckland

Michelle Honey
School of Nursing
University of Auckland

Lisa Stewart
School of Nursing
University of Auckland

We present a project that involves undergraduate nursing students working in small groups using a wiki to develop a collaborative glossary of health specific terminology. We locate our research – using a randomized control trial – within the scholarship of teaching and provide the rationale for adopting this approach to our research. We then provide two alternative evidenced-based approaches to innovating with technology –scholarly teaching and reflective teaching – and show how the three approaches can provide multiple pathways for technology innovators to take an evidence-based approach to their work so that we learn from the past and inform future teaching practice.

Keywords: Web 2.0, Wiki, scholarly, scholarship, reflective, evidence.

Research Project

Our research project involves undergraduate nursing students working in small groups using a wiki to develop a collaborative glossary of health specific terminology. Previously students were provided with a weekly list of relevant nursing and clinical terms that related to their lectures and case studies. Students were encouraged to be self-directed in becoming familiar with, and understanding the meaning of these discipline specific terms. The change of direction using wikis is aimed at providing students with a medium to gain a more in depth and contextual understanding of discipline specific knowledge and professional vocabulary. This is essential for their future communication in the healthcare environment. The project will also develop additional skills including learning to work cooperatively and collaboratively with each other.

We will be conducting a randomized control trial that will involve a control group (wiki group for an alternative group project) and an intervention group (wiki work for glossary terms). We will adopt a mixed method qualitative and quantitative approach to evaluate the impact of collaborative online learning on dependent variables. The dependent variables include participants' experience of the learning exercise, gains in knowledge and ability to apply their new knowledge to clinical scenarios. Students in both groups will be given: a pre-course test with video scenarios to establish their initial levels of knowledge; a post-course test with video scenarios to measure knowledge gains; and a post-course evaluation to gather information on their learning experiences. Students will also be interviewed to gather qualitative data regarding their experience of learning collaboratively using the wiki. Finally, we will analyze the wiki postings using a marking rubric. In addition to carrying out the research we are also interested in critically evaluating our research goals and research methods to determine the evidential value of this sort of research as compared with, for example, the design research approach championed by Thomas Reeves amongst others (Reeves, 2000).

Evidence and Innovation

As academic developers and discipline academics with a strong interest in educational research we are engaging in the scholarship of teaching and learning to ensure that we learn from the past and contribute to the broader evidential base for technology innovation as we move into the future. This means that we are following a number of distinct steps as we conduct our research (Richlin, 2001) Step one involves identifying a teaching a learning challenge and making a research informed decision regarding the solution to the challenge. Step two involves implementing a change in teaching practice and recording what happened as a result of the change. Step three consists of evaluating the impact of the intervention. Step four consists of synthesizing the results and placing findings in the context of the knowledge base. Step five consists of preparing and submitting one or more manuscripts for publication. Step six consists of disseminating findings through publication and adding to the knowledge base.

The scholarship of teaching is time consuming and likely to be an approach, for the most part, undertaken by educational specialists with research careers that centre on educational research. For this reason it seems prudent to provide alternative approaches to educational research that might be used by discipline academics with less time / less inclination to engage in educational research. This will help to ensure that educational innovations are informed by what has gone before whilst also contributing to the stock of educational research knowledge. Richlin (2001) distinguishes the scholarship of teaching from scholarly teaching by removing the publication process. On one line of argument this means that the findings are not disseminated and, therefore, the stock of evidential knowledge is not increased as a result of the research. However, findings can be shared locally through, for example, research seminars. The model of scholarly teaching therefore provides for drawing on past literature whilst also informing future developments within a local context.

There are those for whom even scholarly teaching will be a step too far. These individuals can engage in reflective teaching enquiry. Reflective practice involves educators thinking about and learning from their own practice and from the practices of others in order to gain new perspectives on the challenges that they face in their teaching. Reflective practice can help to improve judgment and increase the likelihood of taking informed action in teaching situations that are, by definition, complex, unique and uncertain. (Center for Support of Teaching and Learning, 2008). The initial act of reflective enquiry can, therefore, help to ensure that teaching practice is informed by past practice. Reflection can also help to inform future practice. Furthmore, reflective enquiry can be shared with colleagues in a local setting. With ongoing reflection, teaching practice can develop into a systematic inquiry that begins with reflection on teaching and learning experiences but becomes collective when informed by interactions with colleagues, students, and theoretical literature.

Discussion

If we make a distinction between the scholarship of teaching, scholarly teaching and reflective teaching, we can provide multiple pathways for technology innovators – no matter how busy and no matter what their particular career aspirations – to take an evidence-based approach to teaching improvement / enhancement. However, the current educational climate is defined by greater expectations with respect to both teaching and research and in this kind of situation the need for evidence based teaching improvement will need to be championed within institutes of higher education. This is particularly the case in research-intensive universities. One way to encourage evidence based teaching innovation is to connect teaching improvement with university reward and recognition processes so that individual academics are motivated to take an evidenced based approach to improving their teaching.

Grounding the curriculum

Sean Dolan

This article argues that with the advent of online learning and the widespread use of discussion forums, there is an opportunity for faculty to encourage students to collaboratively reflect on their own teaching experience from their own unique viewpoints and contexts. Moreover, this shift towards active participation in online discussions has become essential to the student learning experience so that the full range of views and values from an increasingly diverse and non-traditional student base are shared and reflected. In this way it is suggested that traditional notions of curriculum as being defined and controlled by tertiary institutions are being transformed by the grounded experiences of student teacher practice.

Keywords: curriculum, participation, collaboration, cultural diversity

It is widely recognised that online learning has the potential to transform the teaching and learning paradigm in tertiary education (Garrison & Anderson, 2003). Traditional understandings of the curriculum as the object of study are being challenged as information technology and the widespread use of web 2.0 software transform the ways that students engage with learning materials and with one another (McLoughlin & Lee, 2008). Technological affordances of greater connectivity, participation and collaboration provide faculty with the opportunity to position the student and not the content at the centre of the learning experience (Siemens, 2008). Moreover, as the student body grows increasingly diverse, the need for a culturally inclusive curriculum design has become a central issue for learning (Hannon & D'Netto, 2007). The adoption of asynchronous discussion forums in formal education can be understood as a means of creating a more inclusive design which grounds the curriculum in the students' experiences. While the curriculum may remain static over the duration of the course, the way that it is interpreted and shared by students in discussion forums reflect a more dynamic and relevant approach to student learning.

Constructivist view of the curriculum

The traditional delivery of the curriculum positions students as receivers of information and imposed meanings through pre-packaged authoritative content such as text books or study guides (Boettcher, 2006). Based on principles of behaviourism, transmission metaphors of education view knowledge as being external to the student and transferrable from one person to another (Jonassen, Davidson, Collins, Campbell & Haag, 1995). In contrast, a constructivist approach to online learning is based on the notion that individuals construct their own understandings through experience, maturation, and interaction with the environment, especially active interaction with other learners and the instructor (Rovai, 2007). According to this approach knowledge can be conceived differently by each person (Anson & Miller-Cochran, 2009). Therefore, the defining characteristic of an online constructivist learning environment is dialogue which provides learners with opportunities to articulate their ideas, comment on previous postings and reflect on course content (Rovai, 2007). Discussion forums allow for students as a group to negotiate their own understandings and so the focus is not so much on the curriculum as the object, but students' interpretations of the curriculum based on their own personal experiences in the classroom. This is a very powerful message because it encourages students to regard established theory and concepts as objects to be explored, confirmed, or rejected in the light of experience (Smyth, 1989).

Asynchronous discussion forums have become the most widely adopted tool in online learning and according to Garrison (2003) their use signals a move to "the interactive and constructive potential of asynchronous online learning" (p. 48). Comparing face-to-face with online learning, Swan (2003) found that online discussions are more supportive of experimentation, divergent thinking, exploration of multiple perspectives, complex understanding and reflection. These knowledge and skills can be best elicited from students in lecturer led forums that encourage students to reflect on their own teaching experiences (Richardson & Ice, 2010). A greater disposition to exhibit higher order thinking in asynchronous forums can be partly explained by the time delay between postings which gives participants the opportunity to consider and reflect on their response prior to posting online (Maurino, 2007). In addition, all dialogue in the forums is archived creating a permanent record of students' learning which can be referred to as a means of continual reflection (Lea, 2001). The use of discussion forums allows students to mould and shape their own unique knowledge structures in dialogue with their peers. This means that the curriculum is no longer static or unidirectional, but is constantly evolving, adapting and reflecting a range of contemporary student perceptions and discourse. According to this perspective the formal traditional curriculum is being grounded by student voice and real-world experience. Such a trend in participation "harbinger[s] a radical transformation in who learns from whom, where, under what circumstances, and for what and whose purpose" (Haythornthwaite, 2009, p. 1).

Participation in community building

Effective use of discussion forums encourages the formation of social networks and relations between people. Haythornwaithe (2009) holds that participation connotes contribution to a community whose presence is vital for the effectiveness of online learning, a view supported in numerous studies (Liu, Magjuka, Bonk, & Lee, 2007). The forming of community not only has desirable outcomes for affect but also results in a pedagogical shift from focusing on the outcomes of an individual to considering the learning done by the group (Stahl, 2005). Whereas psychological theories of learning focus on the acquisition of knowledge by the individual, a sociocultural approach conceptualises educational environments as social and cultural situations where individuals and groups construct and express their identities. Social learning theories focus on learning that occurs within a social context and involves personal experiences, observations, and interactions with other individuals (Rovai, 2007). Wenger (1998) considers that learning involves participation in a social world where contribution is always based on situated negotiation and renegotiation of meaning in the world. Included in the community are members at varying levels of knowledge from the novice to the expert and part of the learning process is the novice's socialisation to the group through legitimate peripheral participation. In this way the community as a group evolves and learns, students "create explanations of phenomena that fit their local setting, re-supplying context that is often lost in decontextualised learning, and feeding that information back into the learning environment" (Haythornthwaite, 2009, p. 7).

Collaborative reflective practice

This move towards incorporating reflection and discourse, says Garrison (2006, p. 25), is at "the heart of a meaningful educational experience" and over the past recent decades, the concept of reflection has become a popular and core aspect of the discursive practice of teacher education. The importance of reflection is enshrined in the professional standards for graduating teachers as well as featuring in quality assurance initiatives, course accreditation and teacher selection procedures (Ovens & Tinning, 2009). The origins of the concept of reflective thinking are normally held to derive from Dewey's notion of pragmatic inquiry which posits that all knowledge and theory are ultimately derived from the reflections and experiences of others whose understanding is influenced by their own context, biography and culture. This implies that since all knowledge claims are contingent, new knowledge can only be learned through experiential learning that nurtures reflection on experience and the systematic testing of ideas. Schon extended this interpretation of experiential learning and argued for the promotion of practitioner-derived knowledge which he regarded as being more trustworthy and relevant than received wisdom (as cited in Smyth, 1989). By utilising discussion forums as a way of encouraging collaborative student reflection on teacher practice, the forums become powerful teaching and learning tools because what may be discussed in a forum one day can be applied and put into practice in the practitioner's classroom the next. In forums where there is a range of viewpoints and anecdotes of the student teachers' experiences, prospective teachers can best learn how to critically reflect on practice in social contexts where they have the opportunity to discuss practical problems with other teachers of greater and lesser expertise. Such interactions can not only help them solve immediate problems but also scaffold them from limited to more complex understanding and knowledge about teaching (Dyke, 2009).

Student diversity

Increases in student and cultural diversity emphasise the necessity for change in the way that curriculum is viewed. Curriculum can no longer propose to represent the views and experiences of an increasingly heterogeneous student body. It is widely recognised in teacher education that student teachers often bring with them the prejudices and misconceptions of education that they experienced themselves as students (Braun & Crumpler, 2004). Even when exposed to alternative views and concepts, students will often choose to retain outmoded or old fashioned notions of teaching and learning because to change current thinking requires a significant period of readjustment and confusion (O'Loughlin, 1988). In addition, students' reactions to the social-constructivist learning environments differ depending on their prior experience and communication norms across cultures. Rovai (2007) explains that teacher and students from a dominant culture may not consider how diverse students' cultural backgrounds affect their way of working on tasks and communication and Catterick (2007) questions whether students from backgrounds where more instructive pedagogies are dominant can adapt to the constructivist approach of online learning.

Increased cultural diversity implies a much wider range of opinions and backgrounds meaning that many of the assumptions and strategies that have been made on the part of the curriculum may run counter to the expectations of students from diverse cultures (Catterick, 2007). Pincas (2001) noted that students entering into professional education in a multicultural context not aligned with their culture can experience significant conflict. This is supported by Edmundson's (2009) claim that "e-learning courses are cultural artefacts, embedded with the cultural values, preferences, characteristics, and nuances of the culture that designed them, and inherently creating challenges for learners from other cultures" (Cultural accessiblity).This places greater emphasis on the instructional providers to be acutely aware of their own culture since their world views cannot be separated from the training that they develop (Parrish & Linder-VanBerschot, 2010). For example one of the principal drivers in the New Zealand early childhood curriculum is the fundamental belief on the role of free play for the child and the facilitating role of the teacher (Ministry of Education, 1996). This runs counter to many assumptions made by individuals who belong to cultures that have a tradition in transmission types of teaching that suppose the teacher to be the source of knowledge and the teacher's role to pass on that knowledge to their students (Hofstede, 1986). Because of the cultural divide, a curriculum that has been devised without awareness of how views and values are culturally specific may not take into account other students difficulty in getting to grips with underlying principles and concepts that drive such an approach to education.

However, in discussion forums this can be made the topic of discussion and learning can be enhanced through a consideration of context, experience and reflection on what the text books articulates and the student teachers own thoughts. In this context aspects of learning are rooted in social interaction and contextually bound by the participants own ability to contribute. Online learning acknowledges that theoretical move away from focusing on the individual's cognitive development and instead recognises the importance of social interaction. Interactive features that allow for Dewey-like reflection and group construction of knowledge are the new curriculum. Through support for these learning activities, the students are grounding the curriculum.

Stop lecturing me, I want to learn

Richard Evans,
Learning Designer,
Queensland University of Technology

Anne Matthew,
Associate Lecturer,
Queensland University of Technology.

Re-evaluation of pedagogical practice is driving learning design at Queensland University of Technology. One objective of the design for learning is to support approaches to increase student engagement and attendance in physical and virtual learning spaces through opportunities for active and problem-based learning. This paper provides an overview and preliminary evaluation of the pilot of one of these initiatives, the Open Web Lecture (OWL), a new web-based student response application that seamlessly integrates a virtual learning environment within a physical learning space.

Keywords: physical virtual learning environments, student response systems, engagement, OWL

Rethinking the traditional lecture

Traditional lectures are changing and thought must be put to how the alternatives for increasing student engagement and attendance in physical learning spaces are influenced by the elements within existing learning frameworks: pedagogy, space, technology and people (Radcliffe, 2009; Mitchell & White, 2010; JISC, 2006). If we examine these elements and correlate the pace of change against each one, an interesting paradigm emerges in which pedagogy is not evolving at the same rate as the other elements of the framework.

The pace at which technology is developing is intensifying and offers many opportunities for engaging learners in a variety of learning modes and also offers the possibilities of design-based research (Amiel & Reeves, 2008). The redevelopment of physical learning spaces has been the focal point for many universities seeking to engage staff and students with a range of new approaches to learning and teaching. This rich blend of technology and flexible learning spaces promotes both active and problem-based learning (Bonwell & Eison, 1991; Boud, & Feletti, 1997). In comparison, changes in pedagogical practice in higher education are happening at a much slower pace. Emerging from this disparity is a dynamic interplay between students, staff and technology. This interplay is challenging the value of attendance and engagement in physical learning spaces, especially for traditional lectures to large classes. Why should students attend lectures devoted to content delivery when web technologies and streaming replicate the learning opportunity in a more flexible mode (Corbin, Burns, & Chrzanowski, 2011; Kardong-Edgren, & Emerson, 2010; Dolnicar, Vialle, Kaiser, & Matus, 2009; Dolnicar, 2005)? Should we still just lecture? Empty seats in lecture theatres speak volumes regarding the pragmatic nature of student decisions (Corbin et al., 2011; Dolnicar, 2005).

Non-attendance poses risks for performance and motivation, and diminishes interaction with lecturers and other students (Arulampalam, Naylor, & Smith, 2007; University College London, 2007; Massingham & Herrington, 2006). Yet the decision to attend might be more heavily influenced by whether the student perceives the material or the lecturer to be interesting, or anticipates that the material will include assessable information not otherwise available (Gump, 2004; Westrick, Helms, McDonough, & Breland, 2009). This interplay of elements within the learning framework warrants a reconsideration of pedagogy with a view to improving the quality of the learning experience (Laurillard, 2008a), and this reconsideration should address student engagement and exploit attendance as an opportunity for active learning (Ramsden, 1992; Phillips, Preston, Roberts, Cumming-Potvin, Herrington, Maor, et al., 2010).

Design and concept

A re-evaluation of pedagogical practice presents opportunities to create effective learning environments in both physical and virtual spaces by increasing student engagement in active learning within large lectures (Laurillard, 2008b, 2009; Stacey & Gerbic, 2009). The Open Web Lecture (OWL) is a new web-based student response application developed by Queensland University of Technology to seamlessly integrate a virtual learning environment within the physical learning space.

The technology has been design to facilitate a *live collaborative*; a fluid collaboration between academics and students connected to OWL via the University's Wi-Fi network, using laptops or web-enabled mobile devices. The application offers opportunities for the lecturer and students to post comments, questions, and reply to or 'like' the comments of other participants. OWL facilitates polling of students and instant review of tabulated results. At the completion of the lecture the OWL session is automatically archived for subsequent review. Many of these features instinctively appeal to student users of social networking media, yet avail the academic of control within the University network. Student privacy is respected through a system that preserves peer–peer anonymity, a functionality that seeks to address a traditional reluctance to speak up in large classes. This offers new possibilities for active learning in physical spaces by providing increased opportunities for student engagement, supporting a range of learners and learning activities, and fostering a blended learning experience.

OWL has been designed to enable:

- a virtual learning experience within physical spaces for large group lectures, seminar groups, workshops and conferences
- the creation of a non-intimidating virtual learning environment in which to ask questions anonymously
- the promotion of a learning community
- instant exchange of feedback
- peer support
- opportunities for active and problem-based learning within the lecture.

The pilot

The OWL pilot began in 2010 across three faculties: Education, Built Environment and Engineering, and Law. Law introduced OWL within four core undergraduate units undertaken by second and third year students with five members of the academic staff, all of whom undertook training in the use of the application prior to its use. The faculties of Education and Built Environment and Engineering introduced the application within specific undergraduate units. OWL has also been used to facilitate a number of events for staff and students across the university.

Potential barriers to learning with this new type of technology were identified, including: technical issues in relation to connection and use; financial burden of using personal 3G data and not the university's free WiFi; lack of a device with which to connect; equity issues associated with the quality of the learning experience for those students unable to or electing not to connect; and the potential for misuse/inappropriate posts. These potential barriers were addressed through a number of initiatives. A preliminary and in-class support model, offering both technical and pedagogical support was introduced. The focus of the preliminary support was on the effective design of learning activities to integrate the technology within lectures and user training. The university's student help desk and the dissemination of instructional material provided preliminary support for students, while in-class technical assistance was provided for the first lectures using OWL. Students were encouraged to connect to the web application via QUT's WiFi, eliminating any financial burden on them. The QUT Library loaned laptops to students in need of a device to connect to OWL; however, there was a low student uptake on loans for this purpose.

Use of the OWL application was optional for students. In order to ensure that OWL could still be used as a springboard for active learning for students either unable to or choosing not to connect, a number of initiatives were implemented. Where OWL was used in lectures, the lectures were recorded with screen capture and made available via podcast and the units' websites. Where polls were conducted, hard copies were distributed and made available for download from the unit's website. The lecturer was able to display a live stream of posts or poll results to direct/stimulate class discussion on the projector. In this way students not wirelessly connected could still enjoy the benefits of the stimuli provided by the learning activities occurring within OWL.

Davies and Lee have warned that virtual education involving engagement with social networking technologies will increasingly have to cope with the potential for malign user behaviour as the 'virtual education world' expands (Davies & Lee, 2008, p. 260). While social networking sites offer effective and popular means of facilitating communication, there is no guarantee that student users will adhere to a university's internet use agreement. Universities seeking to minimise potential for offensive or potentially defamatory postings would prefer to have the capacity to take down posts. The OWL application provided functionality to 'warn' and 'block' students at the lecturer's discretion, and students were aware that the lecturer could see the identity of all student postings. While novelty posts occurred on first use of the application throught the pilot, the expectation of appropriate behaviour rendered the control functions obsolete without exception.

While OWL provided opportunities for greater connectedness within the lecture environment, 'connectedness per se does not ensure interaction let alone emergent learning' (Williams, Karousou, & Mackness, 2011, p. 51). Lecturers were encouraged to use the virtual environment created by OWL as a springboard to active learning through high quality face-to-face, peer–peer, student–lecturer interaction (Williams et al., 2011; Braxton, Milem, & Sullivan, 2000; Popkess & McDaniel, 2011). The live stream discussion was used *by the lecturer* to pose questions to students and *by students* making comments about the lecture content and posing questions to the lecturer or other students. In some units students were encouraged to use the live stream discursive to generate checklists and terminology dictionaries. A number of units used OWL as a platform for small group problem solving, followed by an OWL poll devised to provide feedback to students as to the extent of their understanding of the lectured material and how it should be applied to the problem.

Preliminary evaluation of the pilot of OWL survey results

The OWL student surveys captured a range of data regarding their use of the technology, level of engagement and method of participation. All students attending the last lecture of the semester for each unit were invited to participate in the survey and 283 students completed it. The data collected was de-identified and grouped by faculty and unit for analysis.

Table 1: Preliminary pilot survey results

Survey question	Strongly agree	Agree	Neutral	Disagree	Strongly disagree
The lecture sessions using OWL were engaging	24%	52%	22%	1%	1%
OWL helped me to get involved in the lecture session	24%	38%	28%	7%	3%
The learning activities in lecture sessions using OWL were relevant	32%	49%	16%	3%	0%

As illustrated in Table 1, the data collected presents evidence of the impact on student engagement, with the survey results showing lectures that used OWL were 'engaging'. If we correlate these figures against the student response to the question 'OWL helped me get involved ...' the emergent pattern provides us with insight into the impact of this type of technology on the student learning experience. The relevance of the learning activities was a key aspect of this inquiry, showing a high proportion of positive feedback that was apparent throughout the whole sample and not isolated to engagement-focused questions. The trends in the survey results are consistent with earlier research into the effectiveness of using personal response systems or 'clickers' in lectures. The findings are consistent with those of Hunter Revell and McCurry, who found that students both enjoyed and were comfortable using the technology in class and, further, that students and faculties' perceived such technology to be 'effective in engaging students, fostering critical thinking and improving learning outcomes in both the small and large classes' (Hunter Revell & McCurry, 2010, p. 274). The low level of negative feedback from students was assessed through analysis of those students' responses to the survey's open-ended questions, particularly 'Comments and suggestions for improvement'. This revealed that their negative experience was related to the lecturer's use of the technology or the student's capacity to connect to OWL.

Conclusions

The rapid pace of technological innovation offers education unique opportunities for live web-based applications like OWL to continue to evolve, blending the physical and virtual space to engage learners and challenge the interplay between pedagogy, space, technology and people (Radcliffe, 2009; Mitchell & White, 2010; JISC, 2006). As we seek opportunities to rethink pedagogical practice, applications like OWL have shown their potential in learning and teaching. As the pilot of OWL continues throughout 2011, the preliminary data collected is serving to inform the future direction of these types of technologies within Queensland University of Technology.

Recent developments in virtual worlds and their potential impact on their use in higher education

Helen Farley
Australian Digital Futures Institute (ADFI), University of Southern Queensland

Educators have been quick to spot the affordances of virtual worlds (VWs) for authentic learning, distance education and for creating community among students. Though the affordances for many disciplines are obvious, there have been significant barriers to the widespread adoption of virtual worlds in the higher education sector. This paper examines some of the recent developments in VWs, user interfaces and company policy that may have a significant impact on the uptake of VWs. Some of these developments include simplification of user interfaces, increased options for VW hosting and changes in pricing policy. Future developments such as the advent of Microsoft's Kinect and the availability of VW apps for both Apple and Android devices are also considered.

Keywords: virtual worlds, Second Life, Kitely, OpenSim, Multi-User Virtual Environments

Introduction

With the widespread availability and accessibility of Virtual Worlds (VWs), educators are no longer restricted to the physical and geographical limitations of their institution, community, state or even country. Just about anything that can be conceived can be created in a virtual environment. VWs enable educators to leverage social connections and learning methodologies in order to transform basic approaches to learning and communication. Generational, professional, historical or gender gaps become obsolete in an environment where users cooperate to create knowledge and experiment with identity in collaborative spaces. Users, via their avatars, learn how to solve problems in the design by means of creation and modification of their own content. This intrinsic culture of participation suffused with pervasive learning makes VWs dynamic and stimulating learning environments (Ondrejka, 2008: p. 229). In spite of the obvious potential of VWs to address many of the issues around authentic learning, distance education and the formation of student community, the uptake of virtual worlds in higher education has been piecemeal and limited. This paper investigates some of the recent developments in virtual worlds which may impact the perceived barriers around their wider adoption.

A Virtual world (VW) is a computer-, server- or internet-based virtual environment that allows participants to move around and use various forms of communication (text chat, voice chat or instant messaging). It allows participants to create a virtual identity which persists beyond the initial session (Maher, 1999: p. 322; Ritzema & Harris, 2008: p. 110). The term was coined by Chip Morningstar and F. Randall Farmer in 1990 (see Morningstar & Farmer, 1991: p. 273) and is often used interchangeably with 'Multi-User Virtual Environment' (MUVE) (see Castranova, 2001: pp. 4-5). Second Life is one of the most well-known VWs probably due to the intense media scrutiny it has attracted, but many others exist such as OpenSim, Active Worlds, IMVU, Twinity and Blue Mars. VWs are populated by motional 'avatars'; the term is derived from Sanskrit and used in Hindu mythology to denote the earthly form adopted by a deity, commonly Visnu (Leeming, 2001). In VWs, this term denotes the representation of a character, controlled either by an individual. The choice of avatar can reflect a player's personality, gender or ethnicity. It is also possible for a learner to assume a completely different identity which in itself may constitute a significant learning experience, particularly important in role-playing scenarios (Annetta, Klesath, & Holmes, 2008: p. 2). In addition, they are able to communicate with large groups of avatars (via voice- or text-chat or asynchronously with podcasting or notecards) or communicate more intimately with a single avatar (using instant messaging) (Tashner, Riedl, & Bronack, 2005: p. 6). Avatars are able to interact with and modify the virtual environment and are even able to interact beyond the confines of the VW if objects are linked to web pages (Tashner, Riedl et al., 2005: p. 6).

Recent developments in VWs

In line with other technologies, VWs have matured rapidly in response to user demand, developments in social networking applications and with improved performance of computing hardware. Other factors have also driven these changes including potential applications, a changing economic environment and an increased familiarity with comparable virtual environments such as those encountered in Massively Multiplayer Online Role Playing games (MMORPGs) such as World of Warcraft.

Second Life

The discontinuation of the Second Life education discount
Second Life is the most popular VW used by educators, boasting around 16 million user accounts. From the very beginning, Linden Lab, the creators of Second Life, encouraged educational institutions into the environment by offering a 50 per cent education discount on tier fees and the purchase of land. Many Australian and New Zealand universities entered the space including the University of Southern Queensland, the University of Queensland and the University of South Australia. The response was strong and a vibrant educators' community was soon established, along with the lively Second Life Educators Mailing List. From the first of January 2011, the education discount was discontinued by Linden Lab. The outcry was enormous – there were many expressions of anger and disbelief on the SLED List – and many institutions pulled out of Second Life entirely (Chapman, 2010). For example, the University of Auckland will move out of the environment once their current lease expires (Young, 2010). Two things happened as a result of this. First, many educators looked for low cost alternatives. For example, the University of Auckland increased its stake in OpenSim. OpenSim is a virtual world that looks very like Second Life but is instead based on open source software. It can be housed on an organisation's own servers or there are a number of external hosting services available. Though hosting costs are significant, they are generally less than the cost of maintaining a Second Life presence as long as the technical expertise to maintain the OpenSim instance is available. The second thing that happened was that educational institutions began to look more seriously at sharing Second Life sites. Most spaces are not used by an institution all of the time so it is practical for two or more institutions to share a space. This becomes particularly viable when considering institutions that do not share time zones.

The closure of Teen Second Life
Another significant change was the closure of Teen Second Life. Since the beginning, Second Life required that people who register be over 18 years of age due to the adult content (some sexually explicit, gambling and so on) present in Second Life. In parallel, a Teen Grid was set up with registered users between 13 and 18 years of age. Adults who wanted to work in the environment – for example educators – had to undergo rigorous security checks and were restricted to strictly circumscribed parts of the grid. Teen Second Life was closed in at the end of 2010 (Joseph, 2011). At the same time, Linden Lab decreased the required age for registrants in Second Life to 16. This was significant for higher education institutions because there had always been a problem taking first-year students into the environments as many students were just 17 years old in their first year and could not enter the environment without contravening the Second Life terms of service. This is now no longer an issue with the decrease in the age restrictions.

Changes to the User Interface
Though many saw it as a retrograde step, in March 2011 the Second Life viewer was released with two modes for use: beginner and advanced. In 'beginner' mode, the interface is much simpler with only a limited number of avatars to choose from, there are no menus, no inventory to tussle with and access to a mini-map (Nino, 2011b). To date, one of the biggest impediments to educator adoption is the learning curve associated with navigating the user interface and environment. Students have identified the difficulty of using a complicated interface as a significant issue when using Second Life (Sanchez, 2009: pp. 29-30). With the option of using the beginner mode, this problem has been significantly addressed. For most activities that students are likely to engage in, the

features of the advanced mode are not necessary. For example, most educational activities won't require students to teleport between destinations or rifle through their inventories. Time that was once devoted to interface orientations can now be redirected towards richer learning experiences. In addition, it is possible to switch between beginner and advanced modes such that students can familiarise themselves with the environment in beginner mode and switch to advanced mode once a level of familiarity and comfort has been achieved.

Ease of registration

When Second Life first came to the wide attention of the public in 2007, only some 90 per cent of users who registered went on to visit Second Life itself (Sanchez, 2009). One of the main reasons was perceived to be because of the difficulties associated with account registration. In these early days of Second Life, a user had to choose from a limited number of surnames and common first names soon became unavailable such that it could take several attempts before an account could be successfully registered. In November 2010, it became possible for Second Life users to register with a name of their choosing (Nino, 2011a). Also, users could also use a display name which could be changed as the need arose. Changes to web-based registration interface further simplified the process. Users could choose a starter avatar when they were registering via the Second Life webpage, before entering the environment. Previously they were required to choose an avatar and alter its appearance within the environment itself. A user's first minutes in Second Life are frequently stressful, and this was compounded by worrying about their avatar's appearance upon arrival when users feel most vulnerable. It also became possible for educators to post a SLurl (Second Life URL) on a webpage or in a Learning Management System to facilitate registration and to ensure that students emerge into the environment at the correct destination. When a student clicks on this link, he or she is guided through registration and when they log into Second Life, they arrive at a destination of the educator's choosing. This is helpful when students are using beginner mode as they are unable to teleport readily to other destinations.

For many institutions, Second Life remains the easiest way to access a VW and in spite of the removal of the educational discount, still is the most cost-effective way of maintaining a virtual presence, especially if there is a lack of appropriate technical expertise within the institution to maintain an alternative system. In addition, recent changes to the user interface and registration procedure have ensured that Second Life remains a popular choice for educators.

Kitely

As well as there being changes in how virtual worlds operate, there are significant developments in how they may be accessed and hosted. Kitely is an on-demand virtual world provider which enables users to visit the Kitely website, log in with their Facebook credentials and create a private virtual world region (or 'sim') (Touchner, 2011). Currently, Kitely is providing OpenSim regions but other virtual worlds will be available using this simple log in method within twelve months. As the owner of the region, a user is able to decide who can access the region – for example, a specific group or class – or it can be made public. The beauty of Kitely is that an educator will only pay for the time that the world is actually being accessed. Once there are no users in there, the region closes and the server resources are directed towards a region that is in use. There are a number of advantages to this approach:

- Very little technical expertise is required; the VW is hosted externally;
- The sim owner pays a small amount per user per hour the sim is in use. Very soon there will be revenue streams available to Kitely users so that it will be possible to monetise projects;
- Because each region is standalone, security issues are minimised. Only avatars that are authorised can enter the space; and
- Because Kitely is using OpenSim, it is easy to upload freely available OAR files which means that educators are easily able to upload one file and create a complete environment. OAR files are readily available from a number of sources. This also makes VWs infinitely scalable with many instances of the same region able to run concurrently, allowing large numbers of students to access the region. This has been an ongoing issue for Second Life and OpenSim where only limited numbers of avatars can be in the one region concurrently.

Though Kitely is already highly functional, a number of developments are planned that will enhance its useability, including increasing the number of login options to include the use of Twitter or Linked In credentials, and Learning Management System (LMS) integration. Kitely is a low cost and low risk way for educators to access virtual worlds, and should ensure that secondary educators will have increased opportunities to leverage the affordances of VWs.

On the horizon …

The ways in which we interact with VWs is set to change. Already a number of iPhone and iPad apps are available to allow limited access to VWs including Pocket Metaverse and AnsheX Client to access Second Life, a Blues Mars app can access that VW, and IMVU2Go, Hide and Seek by IMVU, and IMVU Chat to access that social space popular with teens. As yet, because iPhones and iPad are not compatible with Flash, the interactions are limited and don't offer the full VW experience. The range is even more limited with Android devices however there is an app called Mobile Grid Client which offers limited interaction within Second Life. It can be reasonably expected that given times, a greater range of apps will become available on both platforms that will allow greater interactivity within VWs. The Microsoft Kinect flags some changes in the way we will physically interact with VWs. Already the Kinect has been hacked to allow hands-free interaction with Second Life, The Nintendo Wii Balance Board was similarly hacked to allow hands free movement in the virtual environment.

With changes discussed including changes to the Second Life pricing and age structure, user interface and registration, the emergence of new hosting models as with Kitely, and the increased range of devices able to access virtual worlds, it seems likely that VWs will gain more traction within higher education, educators keen to exploit the unique affordances these environments deliver.

Teacher engagement in a Web 2.0 world: Developing your online teaching and learning Community of Practice

Flagg, Edward
Te Puna Ako
Unitec Institute of Technology

Ayling, Diana
Te Puna Ako
Unitec Institute of Technology

Recent developments in web-based tools have presented new opportunities for teachers and learners to engage in new ways, not only with their specific discipline, but also with themselves, with each other, and their learning. Online Communities of Practice (CoPs) serve not only as clearinghouses for what teachers already know about a discipline, but also as places where new knowledge and skills are developed. They can be a place where professional identities can be shared and grown as knowledge and skills are grown; they can provide space for ideas to be shared, considered, developed, and then used by all members of the CoP; and they are certainly a place where we are able to confront and develop the ways in which we learn.

The researchers are two academic developers currently at Unitec Institute of Technology. In the Spring of 2009, the researchers, as technology stewards, created “The Teaching and Learning Community at Unitec” (T & L Community), an online CoP (http://tlcommunityunitec.ning.com/). The T&L Community is where teachers share and develop teaching and professional resources as well as announce events such as professional development opportunities, conferences, and other gatherings. Members participate in conversations through blog posts and comments, real-time chat and themed chat sessions. This new tool for engaging teachers with each other and their profession resonated with the early members and the CoP began to grow twice as fast as the technology stewards had anticipated.

To accommodate this growth, the site architecture was revamped once and the site was redesigned twice. Today the T&L Community at Unitec is the largest online teaching and learning CoP in New Zealand, with more than 300 members from across the nation and the world. The site hosts a range of resources, smaller communities of practice, information and guidance. The site is well used by the members and the stewards continue to receive positive informal feedback.

This paper explores the background, context and aims of the research, presents preliminary findings, and

presents the methodology for further data collection. The paper draws early conclusions and implications about using online communities of practice in a teaching and learning environment.

Keywords: online community, community of practice, social media, collaboration, teacher professional development.

Background

In the course of our work as academic developers for a New Zealand Institute of Technology, the authors built a small handful of online Communities of Practice (CoPs) in September of 2009 for our teaching staff. One of these CoPs, "The Teaching and Learning Community at Unitec" (T & L Community - http://tlcommunityunitec.ning.com/) had by early 2011 evolved into New Zealand's largest and most active online teaching and learning CoP, with over 300 members from across New Zealand and around the world.

The T & L Community is a place where teachers share ideas and experiences, create resources, form their online professional identities, join groups and announce events. The site is, as Wenger, White and Smith (2009) remind us, a location for social learning with three basic characteristics, a Domain, a Practice and a Community. It's domain is Education, more specifically, it requires members to have education as a fundamental core in their professional identity; the Practice is a sustained, shared engagement with other educators in the areas of design, facilitation, assessment, evaluation, professional development, and scholarship; and the Community fosters social learning with relationships built on trust, mutual engagement, well-managed community boundaries, and members willing to take leadership roles to sustain and develop enquiry. The TLCommunity is where teachers connect and it has become an essential part of our work as academic developers.

Context

Budd told us back in 2005 that web 2.0 technologies can create a richer user experience, where it is easier for people to participate and collaborate. We agree. Taking our lead from Wenger, White and Smith (2009), who trained educators to create online "communities of practice" and encouraged educators to become "technology stewards" rather then transmitters of content, we created the T & L Community so that teachers could use the technology for something Wenger (2009) reminds us is fundamental to our humanity: social interaction. More specifically in our context, we saw it as an opportunity to facilitate the teacher-to-teacher interaction that builds a real sense of community as it builds teacher capability – focused, purposeful, and immediately useful conversations, resources and support.

However, practitioners (of any practice) will not necessarily move easily into an online CoP. Reynard (2009) identifies the key challenge for those who drive a CoP is to ensure that their members have the confidence, learner autonomy and collaborative learning skills to participate in any learning community. An online community invites members to develop the skills of active, engaged and productive participants in their practice and in their own professional development. Often, this can be as daunting as it is inviting – it makes us publically accountable for our practices and for our professional growth. Not every teacher is ready to dive headlong into those waters.

Here is the good news - the online CoP invites teachers to practice the three skills that both teachers and students will need in the future: to be confident in publicly publishing our ideas (representing ourselves and our thinking online as well as creating and developing an online presence); to be autonomous learners (evaluating content, creating and customising professional profiles, maintaining our public workspace and writing reflectively in a public space); and to be able to work collaboratively with others (sharing content, joining groups and networks, making and developing contacts, posting messages, using collaborative tools effectively, and so on).

This, of course, is the very business of a CoP, to share and manage the knowledge, skills and values around a specific practice. For teachers, the invitation is to be engaged and creative in our identities as teachers and practitioners in ways that we expect our students to be in their student identities and in their developing identities as novice practitioners in their disciplines. As the site grew, it became clear that an online CoP for teachers is an ideal way for teachers to build capability.

And grow it did. The first 15 months brought great development for the site and for the researchers (that story is at http://tlcommunityunitec.ning.com/profiles/blogs/our-story-so-far-the-tampl). The architecture and design have been redeveloped. The tone and the content of the site has a more global nature than before. We have noticed the growth of special interest groups and the rise in activity in those groups. The site is dynamic and continues to grow and evolve.

What has become apparent is the need to undertake some research to evaluate the quality of the participants' experience, and to ensure we continue to meet their needs. In 2011 we will undertake a small research project to evaluate effectiveness and gather qualitative data on which to base further interventions.

Aim

The aim of this project is to explore the ways in which teachers engage with the Teaching and Learning Community. We have two aspects we wish to explore – individual participation and community cultivation.

In addition, we want to explore the role of the technology stewards in the process and content of the community. We want to know how teachers perceive the planning, resources, organisation of events, responsiveness and contributions of the technology steward team.

Method

This study is of three months duration. It will employ a single survey and an examination of the Teaching and Learning Community website using platform observation and Google Analytics.

In the first phase of the study a literature search was conducted. The review was presented as a topical interest paper at the New Zealand Cooperative Education Conference in Napier in April, 2010 (Ayling and Flagg, 2011).

In the second phase of the research, the researchers have taken a two-pronged approach: we have sent out a survey to all members and we and have data-mined the site using Google Analytics and basic platform observation (of resources, member data and other artefacts) to gather basic demographic and usage information.

The purpose of survey is to find out how members are participating in the community, what they would like changed, and what they think of learning and technology from their experiences of participating in an online community. We will also glean data that demonstrates users' understanding of the Domain, application of the site's resources in their Practices, and how their sense of the Community is working in their social learning within the CoP.

The members will be asked to reflect on their engagement with resources in their role as a teacher. Our particular interest is in the development of teachers' confidence and capabilities in an online environment. The site is deliberately designed to support teachers to learn, so this information is critical to assessing the success of the site.

The members will be asked about how they interact with a regular update from the site. This information will provide us with the detail of how teachers participate with the technology stewards and communication. The members are asked to give details of the number of times they have interacted with various tools and processes.

The purpose of this question is to ascertain whether members are at beginner, novice, competent, proficient, or expert level of engagement. The members will be asked for feedback on the privacy settings of the site. This information will ensure the technology stewards respond to the members' desires. The members are asked to comment on how the site is functioning and invited to make suggestions for further improvement

To ensure that the date is academically rigorous, the researchers will triangulate by data mining the website. We have used Google Analytics to gather basic details of the number of people accessing the site daily and the most common use members make of the site. In addition, the researchers will be recording the number of members, new members, blog posts, groups, and exploring data which members have publicly shared on their profile pages. These observations and the results of the Analytics are discussed below.

Results thus far

Who are the members of this online Community? How do they identify themselves? What do they do online and where are they from? They come overwhelmingly from Auckland (81%), which one would expect at an institutionally-based CoP in that city, but members log in from Australia, Fiji, Bahrain, the US, Canada and all around Aotearoa / New Zealand. Not unsurprisingly, most members (81%) report working at Unitec at the time they signed up.

In terms of identity, almost twice as many members (31%) identify as female than as male (17%) while a slight majority of members overall (52%) preferred not to identify their gender. Most members are teachers (34%) or staff developers (29%), followed by institutional researchers (8%), librarians (6%), senior lecturers (6%) and programme directors (4%). The remaining members who provided an occupation at the time of joining the Community were divided between other tertiary institutional positions and private education providers and consultants. Overwhelmingly, the members are front-line teachers, working to develop either students or staff.

In terms of online identity, a simple majority of members (62%) claimed to have an online presence. As we might expect, slightly over half (52%) reported that presence to be on Facebook. A quarter (26%) of the CoP members claimed to have a website of their own while a tenth reported being on Twitter as their main online presence, and a handful each claimed to have blogs (6%) and LinkedIn Profiles (6%).

Interestingly, just over a quarter (27%) had uploaded a photo of themselves to their profile page in the CoP; we feel that uploading an identifying photo is one indicator of a strong presence in any Community, and as the literature show us (Wenger, et. al. 2009), more than three quarters of the members of any online community will take the valid role of passive consumers of community cultural artifacts (resources, knowledge, skills and values). This interests us because on the face of it, this indicator of online presence fits well with the definition of Community of Practice, and we want to know if our members and their online behaviour fit within the model we are using.

The last two indicators of a strong online identity we explored was members' confidence in finding ideas and publishing ideas online. When asked if they had confidence in finding ideas online, somewhat more than half (57%) said they were 'confident' and everyone else (43%) said they were 'very confident'. The more difficult skill is in publishing ideas - Many (30%) said they were 'not confident', about half (51%) said the were 'confident', less than a fifth (17%) said they were 'very confident', and a wee few (2%) said they simply were not interested in publishing their ideas online. As with all CoPs, the TLCommunity has drawn together experts, practitioners and novices into one digital habitat.

What behaviours are evident to indicate a strong online presence and leadership in the Community? Resources are created and developed through our blog posts while discussions on specialty topics in education are held in groups. A strong online presence would be demonstrated by the number of resources a member creates and shares (blog posts) and participation in a variety of discussions the Community hosts (groups).

At the time of analysis, 254 resources (blog posts) had been created, 223 of them (88%) by the two primary drivers of the CoP. Another 25 posts (10%) had been written by four other members of the Community, and the rest were one-offs by various members. While this behaviour seems to contradict members' perceptions of themselves, where a clear majority (68%) claimed they were 'confident' or 'very confident' of publishing ideas online, it seems to line up with the idea that most CoP members would be valued lurkers, reading others' ideas but not sharing any of their own.

The Community hosts fourteen groups, all of them education-related, with an average of 15 participants per group. Many members have overlapping interests so many of these participants will be the same members. This indicates that while there are only a few drivers of the CoP, and most members would prefer to consumer the Community's resources than produce them (again, this is perfectly normal for an online CoP) there is a circle of members willing to develop their knowledge and understanding through conversation. These three circles of participation pretty much define the behaviour of the typical CoP (Wenger et. al., 2009).

Finally, we have usage data for the month of August, which indicates that even though most members are not creating resources or sharing ideas, a great many are accessing what is on the CoP. In August 2011, the site received 904 hits, or slightly over 29 hits per day. With an average of 10% of users accessing the site daily, the large portion of members who do not produce Community resources seem interested in consuming them.

In the end, we have a well-used CoP, characterised by a wee core of members, primarily the technology stewards, driving the Community, who are essential to the sustainability of the Community; a slightly larger group of members trying their hand at sharing ideas and participating in group discussions; and on the vast periphery, the majority reading but not sharing. By all appearances, it is a classic, healthy Community of Practice, creating, developing and managing knowledge, skills and values.

Implications

By analysing basic usage data, conducting straightforward site observation and by anecdote, the T&L Community seems to be a place where knowledge is managed so that members develop their teaching practice, their collaborative skills, and for some, their confidence in sharing resources and ideas. For the drivers of the community, Wenger's 'Technology Stewards', it appears to be an excellent use of time, attention and resources in developing our academic staff. What makes this CoP interesting and successful? We suspect people come for the resources, blog posts, groups, events, and the ability to communicate quickly with colleagues who share the context of being in the CoP. We are hoping to confirm that with our survey.

The last piece of the puzzle for this project will be revealed by our month-long survey, already underway, which asks members about their understanding of the purpose and function of the CoP, their actual behaviours within the Community and their attitudes about its functioning. These findings will be shared with the ASCILITE community this December in Hobart.

The role of tutors in facilitating online student engagement

Lorraine Fleckhammer, Lisa Wise
Faculty of Higher Education, Lilydale
Swinburne University of Technology

This paper discusses the role of the tutor in developing an online learning community to promote student engagement for large online cohorts. Information overload on the discussion boards was addressed by separating students into streams of 150 – 200 students promoting greater student and staff engagement. A new feedback strategy was introduced to streamline the assignment-marking process and this feedback process has proved to be more socially engaging than traditional feedback via comments embedded within student assignments. The new feedback model involves commentary on assignments, which becomes a "conversation" with the student rather than a series of comments embedded within assignments. In addition, easier access to comments allows greater opportunity for moderation of marks by tutoring teams and for "feedforward" for subsequent assignments. The importance of the level of engagement and commitment to teaching of the tutoring staff has been made apparent by the serendipitous changes to the tutoring role.

Keywords: teaching teams, online learning, student engagement, learning community

The importance of student engagement

Student engagement has been defined by Macquarie University (2009) as 'the extent or quality with which students are committed and actively involved in their learning" (Macquarie University, p.1). This definition suggests student ownership of their learning by emphasising the student's active involvement with the learning process, rather than emphasising interactions with other students, with academics or with institution. On the other hand, student engagement surveys such as American National Survey of Student Engagement (NSSE: 2009) and the Australasian Survey of Student Engagement (AUSSE: ACER, 2009) have an implicit definition of engagement embedded within their questionnaires. This implicit definition emphasises engagement with peers, with staff, with the institution and with specific technologies or types of learning activities, thereby ensuring that responsibility for student engagement does not lie solely with the student.

Macquarie University also suggests that student engagement requires staff engagement, however little is said about the nature of staff engagement. Is staff engagement a matter of quality or quantity of intellectual interaction with students? Does staff engagement also involve being socially engaged with students? Do teaching staff need to be deeply engaged with the materials they are teaching, or with the teaching process itself? Or should staff engagement reflect a strong identification with the institution offering the course they are teaching? Staff engagement is as difficult to define clearly as student engagement, and neither term gives a clear indication of what exactly is being engaged with. Whatever the concept entails, it is generally agreed that successful students tend to be more engaged with their studies, and this is facilitated by engaged and enthusiastic teaching staff within a supportive learning environment (Bryson & Hand, 2007).

Student engagement in the online environment

As more university services go online, and many of the incoming cohort of students have grown up in the digital age, it is becoming increasingly important to understand the effects of online learning practices on student engagement (Krause & Coates, 2008). Online students are, in general, positive about their study, particularly with regards to its convenience in terms of independence of location and time (see LaBay & Comm, 2004 and Li & Irby, 2008 for a review of the literature). However, mode of delivery has a significant impact on attrition rates, in that online students are more likely to drop out than on-campus students (Patterson & McFadden, 2009). Although some online students drop out of their courses for reasons specific to the individual student (e.g., work commitments, ill-health), Willging and Johnson (2004) report that i) feelings of isolation, ii) disconnectedness, and iii) technological problems are common explanations for the high attrition rates in online courses. In other words, many online students drop out from their study due to a lack of engagement with the online learning environment.

Online students also have higher expectations regarding interaction with teaching staff (LaBay & Comm, 2004; Li & Irby, 2008) than on-campus students, presumably because staff members tend to be more visible to them through the interface of the online course materials than their fellow students. Online study is, for the most part, a solitary pursuit, whereas on-campus students have greater opportunity to engage with their student peers in the course of their daily activities on campus than they do with the teaching staff. Online students, probably more so than on-campus students, need to be able to engage with their learning in an independent style, but it may be that overall academic engagement can be facilitated for this cohort by developing a greater sense of social engagement.

Online Learning Communities

Concerns have been raised that the technology comprising a university's learning management system ends up driving, rather than supporting, pedagogy (Deneen, 2010; Lane, 2009). Although this possibility is often cast in a negative light, learning technologies can also have positive effects on teaching practices and student engagement (Coates, James & Baldwin, 2005). With careful educational design, online courses are able to facilitate a sense of being part of a learning community despite the fact that students and staff are separated both physically and temporally (Rovai, 2002). Online activities, multimedia tools and discussion forums can increase emotional engagement in learning environment (Chih-Yan Sun & Rueda, 2011) and provide the necessary elements for a community of learners. Students who participate in a learning community are more engaged with their learning, which in turn is positively related to student outcomes and satisfaction (Zhao & Kuh, 2004). Temporally synchronised chat sessions and asynchronous discussion forums are both important tools in student engagement (e.g., Chih-Yan Sun & Rueda, 2011).

Role of tutor in building a learning community

The Bachelor of Behavioural Studies (BBS) offered through OUA incorporates a major in psychology. Students are able to enrol in OUA programs without a recent history of previous study, a formal high school or equivalent entry score, or undertaking a pre-entry examination. Therefore, teaching staff must cater for large cohorts of students who are very diverse in their literacy, numeracy and computer skills, and may be undertaking the psychology program for a range of reasons. For example, some are upgrading their qualifications, some are enrolling in individual units out of interest, and some are testing the waters before registering into the online program or articulating to on-campus degree programs. Although many students in the BBS program are high achieving students showing independent or intense engagement styles, the majority of students fall into the passive or collaborative category, and there is a very high attrition rate (around 50%) compared with on campus studies (around 10%).

The BBS pedagogy has aimed from its very beginning to build the sense of being part of an online learning community. To give a sense that the teaching team are real people, photos are provided of all the tutors (selected by the tutors themselves) and brief video clips of a range of different lecturing staff. Tutoring staff are mostly Ph.D students, D.Psych students, and practicing psychologists, but also include on-campus teaching staff. The most important criteria are that tutors are passionate about teaching, are technically adept, and have valued the opportunity to work as part of a team that is the online "face" of the university.

The team teaching model within the introductory psychology unit evolved rapidly in response to the unexpectedly high growth in enrolment (Fleckhammer & Wise, 2010). Initially, the Blackboard website was set up to accommodate the whole of the student cohort and a general discussion board was monitored by members of the teaching staff. The discussion board comprised a number of forums with specific functions (General Discussion, Assignments, Technical Support, Social), and synchronised chat sessions were also conducted each week by each of the teaching staff. Students could attend any of the chat sessions. It quickly become evident that, with the increasing number of students, students and staff alike found the discussion forums difficult to navigate due to the volume of information. For example, the "Greetings" forum, for first week introductions had over 350 posts which students found overwhelming. In assignment-related forums, there were too many posts to read and questions were asked and answered multiple times, exacerbating the problem of information overload even further. For example, there were more than ten different threads called "Hypotheses" and these contained very similar questions and answers within them. Although the level of interaction appeared to be high based on the sheer number of contributions, the actual level of individual *dis*engagement increased rapidly because many people could not keep up with the amount of traffic, creating an illusion that there was a conversation happening around them but that they were excluded from it (e.g., " I am a bit confused and maybe I am missing something due to being so overwhelmed"). Out of 2643 discussion forum posts on a discussion board servicing 323 students, almost 20% were written by the convenor in response to student posts. One other tutor contributed 84 responses, but the remaining 5 tutors only contributed between 1 and 16 posts. Disengagement occurred for students and tutors alike and many students turned to private email consultation with tutors rather than braving the alienating maelstrom of the discussion forums.

As student numbers were expected to keep rising, our major concern was to ensure that the teaching staff could facilitate engagement and establish an online presence to motivate student learning. We have established by trial and error that the optimal size for effective participation in discussion boards is between 150 and 250 students led by 3 to 4 tutors. Too many students results in too much information, and too few students fails to achieve a critical mass in terms of maintaining an ongoing level of interaction. Too many tutors can devolve responsibility too far so that no-one actually takes responsibility for maintaining a coherent staff presence, whereas too few tutors does not allow the tutoring team leeway to deal with the inevitable temporary absences due to illness or competing work/family commitments, particularly in the context of a year-long 4-study-period teaching cycle.

In the first study period to use tutor groups, there were a total of 3826 posts across 4 separate discussion boards, servicing between 150 – 200 students each. The same rate of staff student interaction was maintained as in the first iteration of the unit (23% of posts by staff), but in this iteration, half of the tutors posted more than 100 posts each and the convenor was not required to monitor discussion forums. Moreover, because of the separation of discussion boards, each stream of students were only confronted by 1000 posts during the course of the semester, rather than more than 2500 as per the first iteration.

The large online cohorts also necessitated the development of new process for assignment marking as described by Fleckhammer and Wise (2010). Rather than "correcting" student assignments (inserting comments that highlight specific errors, followed by a brief overall comment), tutors 'talk' directly to the student about their work, albeit asynchronously in the form of a written commentary of approximately 300 – 500 words. This is feedback strategy is more socially engaging than embedded comments, and, contrary to the original expectations of the authors, appears to enhance rather than dilute academic engagement. The increase in academic engagement is due to the need to comment at a higher level about content, rather than at the level of individual words and sentences, as tends to be the focus when comments are embedded into assignments. Academic engagement for teaching staff was unexpectedly increased through this method of providing feedback, due to the relative ease of access to comments. In order to read embedded comments, it is necessary to open each assignment document and read through it, which can be a time-consuming process akin to cross-marking the assignment. Comments are now visible directly from the gradebook so that, rather than cross-marking a subset of assignments, tutors can gain an overview of the level of feedback being offered by their peers across all assignments, and to see the range of interaction styles of their colleagues. Marks moderation is facilitated by being aware of types of comments led to what marks, and then cross-marking assignments targeted on the basis of specific feedback.

Not only does the use of tutor teams improve the tutor-student relationship and build on student engagement, but it builds the tutoring skills and overall academic development of individual tutors (staff engagement). The end result is that tutoring teams are now actively involved in setting the agenda for discussions, thereby improving their engagement with students. They are also responding to student inquiries about marking criteria, facilitating assignment preparation, and marking the assignments, thereby improving their engagement with the course content and the teaching process. This type of engagement gives rise a more involved relationship between tutors, and between tutors and individual students, which promotes academic engagement within a feedforward-feedback loop. Increased staff engagement can also lead to improved staff development, such that two of the online tutors without long-term academic career aspirations have now been motivated to convene their own online units. The emergence of tutoring skills can be seen in the increasing contribution of tutors to discussion forums, with experienced tutors tending to provide high levels of interaction (>100 posts per study period) and inexperienced tutors tending to interact less frequently (<30 posts per study period).

Concluding comments

The team tutoring approach has helped to build the level of student engagement among students completing the introductory unit, and there has been a decline in attrition (28% versus 20%), suggesting better engagement of the online cohort of students. Students are making more use of the online learning community fostered by the tutor teams, and the feedforward approach to learning has ensured that they are able to improve their level of academic engagement and acquire more effective study skills. There are also still a number of barriers to student engagement in line with those noted by Willging and Johnson (2004). For example, the implementation of the Blackboard learning management system used by the BBS program has technical limitations in terms of catering for large cohorts. Browser issues and technology challenges appear to be insurmountable for some students, and it can be difficult to address these issues remotely, particularly for under-engaged students.

We have established through our team teaching approach that the role of the online tutor is important in facilitating student engagement in the online environment. Although we have not improved overall student academic performance, there has been a modest reduction in student attrition and we are confident that the level of student engagement has increased for the students who remain actively enrolled in the program through the increased use of discussion forums and tutor interaction.

Engaging training simulations for socially demanding roles

Andrew E. Fluck
Faculty of Education
University of Tasmania

Adam Fox
Schools of Education and Computing & Information Systems
University of Tasmania

Students in higher education preparing for socially demanding roles often encounter role play as a technique for mastering their future professions. Lawyers have ‘moots’ or scripted court sessions. Medical doctors attempt to diagnose the injuries or diseases simulated by actors.

Some pre-service teachers undertake micro-teaching simulations with peers pretending to be pupils (not necessarily compliant ones). However, this is an inefficient use of learning time for the peers, and work is proceeding to develop virtual worlds in which such training can be conducted with simulated pupils.

This paper describes the development of one such learning environment, and discusses the challenges to be met as this class of learning interactions becomes useful in teacher training.

Keywords: OpenSim, simulated pupils, pre-service teacher training

Introduction

Behaviour management is a foremost concern of new teachers and the schools in which they work. Good behaviour management results in more pupil time on task, and this can be measured with feedback (Hattie, 2009). Pre-service teacher training is often criticised for poor connection between theory and practice (Standing Committee on Education and Vocational Training, 2007). Behaviour management is a particular skill where this connection is crucial. Previous work has already been published in the area of behaviour management in social computing learning environments (Fluck & Cruise, 2008) and the social effects of computers in education (Fluck, 2001).

However, in the context of scaffolded learning in campus-based teaching, it is difficult to give all 250 students in a lecture an opportunity to practice behaviour-management skills. To do so would require 250 classrooms in close proximity to the lecture theatre so that new theory could be put quickly into practice. Additionally the 250 classrooms would ideally exhibit exactly that aspect of behaviour management discussed in the theory session.

These challenges mitigate making good connections between theory and practice, but a virtual classroom can overcome these difficulties. Through the use of OpenSimulator USB, it can be replicated 250 (or more) times with ease, and the behaviour of the simulated 'bot' pupils can be identical in each virtual classroom. Each pre-service teacher would be given a USB stick which when plugged into their computer would provide a 3D virtual classroom complete with furniture, interactive whiteboard and pupils. Copies of the USB can also support skills mastery for online/distance students, by downloading onto a local stick. Using Gee's transfer principle, skills acquired in the virtual practicum classroom will provide an introduction to their effective use in real school classrooms (Gee, 2003). This form of training for pre-service teachers will be analogous to the simulator training used by pilots, surgeons and ship captains.

Class based role plays can be very useful in professional training for socially demanding roles such as teaching, but they are extremely resource intensive. In such simulations of professional activity, some students take on client roles, and one individual acts out the professional character. Peer students who take on client roles obtain a useful insight into recipients of their future professional practice. If they seek to maximise their time in the role of the qualified professional, role-playing as clients detracts from this perspective. Therefore we sought to review existing simulation techniques in higher education, and build upon this experience to provide behaviour management training to pre-service teachers using a virtual world.

Literature

Simulations have the capacity to improve skills acquisition and assist understanding of the inter-relationships between theory and practical reality. Gatto (1993) had the view that students who interact with simulations are "better prepared to perform in real situations than those students who rely on other instructional media, such as text" (p.154). Simulations can also engage learners in experimental and experiential learning that provides an opportunity to reflect on the way the associated knowledge and skills can be used (Brown, Collins & Duguid, 1989). Participation in a simulation allows the trainee to observe the impact of each choice without adverse impact on real people/clients. They have the chance to experiment and explore the cause-and-effect relationships between certain clients and intended service outcomes.

A report requested by the government into the integration of ICT into school practice identified fundamental systemic flaws in the pre-service teacher education system in Australia in terms of developing teacher competence in embedding ICTs in pedagogy and practice. In recommending the way forward, Black, Smith and Lamshed (2009) suggested technology also provides an opportunity to transform the practicum through the use of virtual world simulations so that student teachers are able to experience 'real' teaching situations where newly developing pedagogy could be practiced and assessed. Their report proposed future directions related to a suite of virtual world schools as teaching and learning simulation environments.

Mitchell, Stanelis and Travers (2010, p. 66) mapped teachers' professional development to integrate ICT into classroom practice, and subsequently made the recommendation "that a set of online tools be developed to support preservice education in the use of ICT in teaching. This should include communication tools to share good practice and a real-time virtual environment that presents a range of classroom scenarios which feature high quality use of ICT." While the initial objective of this recommendation was to improve classroom practice with ICT, the suggestion that pre-service teachers have access to virtual classes to improve their training was of more general validity.

But how might this be done? According to Sasso (2006), 'Simentor?' is an authoring application created by Access Technologies Group (ATG) thatallows companies to create e-learning simulations that fit their company without requiring any computer programming skill. 'Social Simentor?', a product based on ATG's Simentor? software, is a program designed to help in the social development of individuals with disabilities. This example shows how a generic 'engine' for creating and running simulations can be tuned to a specific purpose.

The Mekong e-sim[8] was an early online role-play-simulation set in the Mekong region of South-East Asia in which participants learn to balance the social, political, economic, scientific and conservation based development conflicts (McLaughlan, Kirkpatrick, Hirsch & Maier, 2001). It is housed within the institutional

8 http://services.eng.uts.edu.au/~robertm/mekong/default.htm

learning management system at the University of Adelaide. However, this is a purpose-built simulation for a single specific purpose.

The 'DeakinSims: Experiences in Learning Experience Design' project funded by the Australian Teaching and Learning Council has produced a set of simulations for use in business studies, engineering, project management, systems analysis and professional practice. These web-based online activities were built on the LiveSim[9] architecture, an open source project providing the underlying functionality. A character server and text-to-speech licensed software are also required. This combination of technologies is hosted at Deakin University and the platform is offered to other institutions (Cybulski, 2010). Most of the simulations used a talking head metaphor, with the underlying activity derived from a set of state transition tables. To some degree this model might help with training in behavior management, but what is needed is interaction with a group of simulated pupils instead of a single individual.

An online simulation 'ClassSim'[10] for pre-service teachers was trialed in prototype by Kervin, Ferry and Carrington (2006). The work was funded by the Australian Research Council and used by 186 pre-service teachers at the University of Wollongong. During the simulation the 'pupils' facial expressions showed their emotional states, and the pre-service teachers could see samples of pupil work. Overall the simulation helped pre-service teachers better link theory and practice.

simSchool[11] is a classroom simulation that supports the rapid accumulation of a teacher's experience in analysing student differences, adapting instruction to individual learner needs, gathering data about the impacts of instruction, and seeing the results of their teaching (Zibit & Gibson, 2005). The simulation is web-based with two dimensional cartoon characters representing pupils in a classroom. Pre-service teachers can review pupil files, then select learning activities for each pupil as the simulated lesson begins. Interactions are from a menu of behavioural and academic topics. At the end of the 'lesson', the pre-service teacher can review a graphical display for each pupil illustrating engagement and internal emotional state. The strength of this simulation is the coherent theoretical background used to determine pupil behaviour to stimuli. A weakness is the stilted conversational style conducted through text alone, and the cartoon nature of visual presentation.

A project currently in train which shows great potential for achieving the desired training result with respect to behaviour management is Virtual PREX[12]. This is being developed in Second Life[13] and will provide a 3D virtual world for pre-service teachers to practice professional experience (also referred to as practicum or workplace learning). Through Virtual PREX pre-service teachers will practise teaching skills prior to practicum placements, use the space synchronously or asynchronously, by themselves or interacting with peers, academics and/or 'bots, record and play back video 'machinima', for self, peer, formative and summative assessment and practise teaching skills with the 'bots programmed to react to certain triggers (Gregory, 2010). This will give pre-service teachers the opportunity to experience a range of scenarios in a risk-free environment. The strength of this proposal is the three dimensional realism of the virtual classroom scenario, and the capacity for avatars to move around within this setting. The unknown quality of the theoretical background driving the interactions has yet to be published.

In summary, there are a range of generic simulation development tools and specific projects in associated domains which can inform the task of providing training in behaviour management in teaching. Our task was to build upon these proposals and come up with something which would serve this purpose and be practical in use. Our response was to transfer a classroom initially built in Second Life to the OpenSim environment, and implement this on a single USB drive. We then added additional avatars representing programmed 'bots which take the part of pupils in the virtual classroom.

Design Elements and Features

Creating an OpenSim USB[14] is simply a case of following the instructions at the Research: USB OpenSim page from the Tasmanian Polytechnic, or if you have an OpenSim USB already, you can copy all of the content

[9] http://livesim.sourceforge.net/
[10] http://edserver1.uow.edu.au/ClassSim/
[11] http://www.simschool.org/
[12] http://www.virtualprex.com/
[13] http://secondlife.com/
[14] http://vw-standards.wikispaces.com/Research+-+USB+OpenSim

to another USB to create a new one with the existing environment and objects on it. The OpenSim USB has been tested on Windows XP (32bit), Vista (32 bit), and Windows 7 (64 bit) operating systems. The software requirements for the virtual classroom are dependent on the user's needs: if you are only going to run the existing environment and edit the classroom, all of the software is contained on the USB and does not require installation on the computer. Running the executable program for the 'bots' will log them into the environment, and requires the installation of the OpenMetaverse library components. This is done the first time you run the program, and is simply a case of confirming that you allow the installation of the OpenMetaverse library. However editing of the code requires the installation of the full OpenMetaverse development library, Microsoft Visual Studio 2010, TortoiseSVN and the Microsoft .NET runtime environment. Exact instructions on how to configure each of these programs is available at the OpenMetaverse website[15].

Starting an OpenSim USB requires the running of three separate programs, each which must be running to be able to access the Virtual Environment (known as Localhost). To avoid a potential software conflict, exit any running copy of Skype, then execute the program \usb-opensim\mowes.exe. Once this is up and running, Apache and MySQL should be displayed as running as well. You then run \usb-opensim\diva-r13981\bin\OpenSim.exe. Next, find out if you are running a 32 or 64 bit operating system: check by right-clicking on 'My Computer' (or 'Computer' depending on your version of Windows) and selecting 'properties' followed by the system tab. If you are using a 32bit operating system, run OpenSim.exe; or for 64bit operating systems, run \usb-opensim\diva-r13981\bin\OpenSim32BitLauncher.exe. Once the corresponding OpenSim program has run and has ended at the point "Region <root> #" leave that program open and then run Imprudence.exe. All of these instructions are also in the ReadMe.pdf which comes on the USB in the root directory. The USB also contains some usefully pdf help guides in the \help\ folder and also includes simple video tutorials for using the Second Life-like environment in the \help\Video Tutorials\ folder.

Construction or editing of the classroom, or anything in the Second Life Environment, is done through the creation and altering of "Prims" which are just basic shapes (squares, tube, circle, triangle, pyramid, cone, etc). Most everyday objects can be created or manipulated by altering the size and position of these 'prims'.

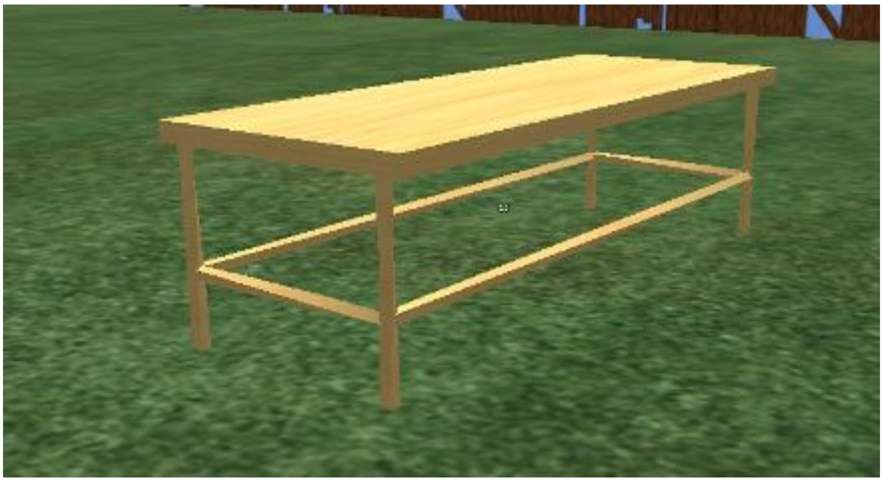

Figure 1: Example of a basic object created using prims

The basic table in Figure 1 is made up of nine Prims which are all cuboids re-sized and moved to make the tabletop (1), the legs (4), and the leg braces ¾ of the way down the leg (4). Once you have created an object, the prims can be linked together so the whole table is one "Object". That object can then be stored in the user's inventory and re-used multiple times. Extended to creating a classroom, the three dimensional veracity of the simulation can be quite accurate, and even the computers and interactive whiteboard in the current version have some limited functionality (see Figure 2).

[15] http://lib.openmetaverse.org/wiki/Getting_Started#How_to_compile_libopenmv

Figure 2: A fully rendered simulated classroom

The pupil bot avatars interact using the OpenMetaverse library of code developed to enable people to build remote controlled Avatars in second life. Using OpenMetaverse it is possible to create a C# program that when run, logs an avatar into the OpenSim USB environment (using the avatar's name and password) and then interacts with the users nearby. The code used is taken from the OpenMetaverse tutorial pages and was edited to suit the needs of the virtual classroom. The program basically takes the username and password given and logs onto that account and then interacts in the ways programmed. The two interaction methods built into the current prototype are reactions to specific words uttered in the public text chat dialogue, and the interactions from specific words said through the in-game instant message (IM) system.

Although the whole process described here relates to a single USB stick, these can be replicated very quickly using a suitable device such as those from NexCopy[16]. The advantage of this reticulation method is that pre-service teachers are able to use the 3D simulated environment and work through a series of behaviour management situations at their leisure using any available computer. The exercise does not require a high bandwidth internet connection free of firewall restrictions, and is therefore less demanding of resources. Also, there is no monitoring of failed attempts to control the class – and thus a more supportive environment to try other approaches to the challenges presented.

Procedures and Rationale

On entry to the OpenSim USB virtual world, the pre-service teacher is able to build and manipulate all of the objects in the classroom. The inventory of the Teacher avatar is kept empty but they can also log in with an Admin avatar and have access to all of the objects used to create the classroom. The preliminary goal of the Virtual Classroom Project was to create a prototype classroom that simulated the visuals of a real life classroom, and create a basic program that could remote control another avatar which would eventually represent an interactive responsive pupil bot. Once the program had been built to allow the bot to read the text comments of users around them, it was possible to link certain commands to actions that the bot performs. The finished prototype pupil will sit down on the command "sit"; stand at "stand"; jump at "jump" and stop jumping at "stop. Also, in this proof of concept phase, pupil bots will repeat phrases after the word "say" and log off the virtual environment at the phrase "goodbye".

Given pupil bots that can be interacted with, the possibilities of scripted conversation, movements around the classroom, etc. are limited only by the programmer's creativity. The next development of the virtual classroom was the expansion and rebuilding on the OpenSim USB to make it portable and thus easily accessible. This step removed the need for an internet connection, and at this point the realism of the classroom was stepped up a notch with the inclusion of miscellaneous objects and specific real world classroom components usually forgotten in virtual worlds (electrical sockets etc.). The next step in development will be the collection of real

[16] http://www.nexcopy.com/

world data and the programming of interactions and responses between the pre-service teacher controlled avatar "teacher" and the program controlled pupil. Our goal is to create an artificial intelligence that will respond to commands from the pre-service teacher based on a database of collected real world responses. A drawback of the prototype is its response to all instances when the trigger words are used in text chat. For example using the sentence "The quick brown fox will jump over the lazy dog" would cause the bot to jump (see Figure 3) even though that was not the intended purpose.

Figure 3: Example of pre-service teacher's avatar interacting with the pupil avatars

This issue is avoided by sending commands through the instant message (IM) system, but this restricts giving commands to each bot individually. It may be possible with a more advanced C# program to include a whole class IM function, or specific person public chat commands.

Discussion and Conclusion

Computer-based systems are used in much professional training to provide extended simulated experience. There are flight simulators for pilots, shipping simulators for naval bridge officers, life-sized computer operated mannequins for nursing students and haptic feedback for trainee surgeons. They have the advantage of providing repeatable training, where mistakes can be analysed and approached again with this insight. To a degree, these simulations can be scaled – made available to very large populations of trainees.

Few such computer-based simulations have been researched to determine their effectiveness imparting the expertise of behaviour management in teaching. This should include the design of each lesson, nature of each pupil, verbal and non-verbal communication – a whole host of socially demanding skills. 'Social Simentor?' and 'SimSchool' are two that focus upon related skills. Other funded projects are active in Second Life, which allows role plays involving geographically dispersed participants. This has a few major drawbacks since access to Second Life requires an excellent connection to the internet to create a viable realistic experience.

A locally hosted virtual environment on a portable USB Flash Drive avoids that problem, because there is no need for an internet connection at all. Our project is based on a virtual classroom built to be as close to a realistic classroom as is possible, developed within the OpenSim framework. Our current classroom is designed to simulate a high school computing classroom, but could easily be duplicated and rearranged to simulate any other subject space with memory capacity to spare. The most important feature of the virtual classroom is the ability to create virtual pupils, the end goal being the creation of artificially intelligent pupils that respond to commands from the teacher's avatar. Using voice recognition and speech to text we hope to make this become an aural/verbal interaction. Pre-service teachers can then try different behaviour management approaches in difficult simulations, to see the outcome of each approach.

Seven simulated scenarios are initially planned in the virtual practicum classroom (see Table 1). At the start of each session an avatar taking the role of the assistant principal will orally introduce the behaviour management policy and the individual pupils of the class.

Table 1: Planned initial scenarios and expected pre-service teacher behaviour management strategies.

Scenario	Expected behaviour management strategies
A range of classroom layouts will be provided.	Choose the layout which will minimise student interaction during circulation. (Dymoke & Harrison, 2008, p. 118)
'Bot' pupil behaviour (standing up, sitting down on their chairs) will be directly related to the volume of the pre-service teacher's voice. This will be replicated into as many classrooms as necessary by putting the current pilot into a USB stick version of OpenSimulator.	Rule reminder: teaching routines (Rogers & McPherson, 2008)
Simulated students will be learning independently and the pre-service teacher will be able to interact by keyboard or voice with each one individually.	Encouragement and re-direction (Morgan, 2009)
Individual simulated students can be directed to undertake a specific learning activity and the pre-service teacher will be able to monitor compliance.	Direction
An individual simulated student (selected at random) will demonstrate off-task behaviour and if addressed in the required way will resume learning.	Scaffolding, proximity and rule reminder (Fields, 2005, p.12)
As #5 but a specific warning will need to be given before the 'bot' student resumes learning.	Support, warning, choice consequences.
As #6 but this time the 'bot' student will repeat the behaviour with a necessary escalated response from the pre-service teacher required.	Defiance responses, cool down chair (Charlesworth, 2008)
A small group of simulated students will undertake off-task behaviour and the pre-service teacher will need to use a variety of strategies to get them to resume learning.	All

If time and resources permit, the range of scenarios can be extended and link to specific aspects of behaviour management theory as advised by experts in the area. We will trial extensively with small groups of pre-service teachers (with ethical approval) and gradually extend this to include larger groups. Data will be collected through short surveys and focus groups to ascertain the perceived usefulness of the simulations.

As we proceed, we see a range of challenges before us. We seek a simulation which:

- is engaging and convincing
- has a theoretical background for artificial intelligence 'engine'
- caters for 'mob rules' – balancing collective v. individual behaviours
- incorporates the affective domain
- is realistic
- includes audio interaction – speech recognition for input and text to speech for output
- is replicable – the same interactions generate the same responses
- contains a series of escalating behaviour management scenarios

To succeed we will need to build upon established artificial intelligence principles. Much artificial intelligence behaviour appears to be database driven, or to derive from exploration of possible system states (e.g. game move variations) for a target pattern. In one possible model "the belief network model updates the stochastic / fuzzy belief assigned to the facts embedded in the network until a condition of equilibrium is reached, following which there would be no more change in beliefs" (Rios, 2010). Other tools that could be deployed include fuzzy Petri nets, for handling both imprecision of data and uncertainty of knowledge by a unified approach. Looking at the other simulations mentioned previously, we believe our front end and user interface are highly attractive and becoming extremely useful. The challenge ahead will be to couple this aspect with theory-driven functionality such as that in simSchool, and engaging these artificial intelligence techniques to overcome the challenges we have identified.

The program is very much in its infancy, with only the ability to react to basic text-based instructions (sit = the pupil sits; goodbye = the pupil logs off) but with a specialist in C# the coding of a fully interactive experience is easily possible. OpenSim works almost identically to Second Life, building, interacting, 3D modelling, and we are expecting to incorporate audio-based input and output shortly. The babble of virtual pupil's voices will be quelled by a gentle instruction from a well-trained pre-service teacher!

In search of ‘graduateness’: Reframing equity of student experience, a transformational approach

This poster depicts key considerations around adopting a transformational approach to curriculum renewal at Charles Sturt University. This enhancement of the student experience must be built on a transformation of the university organisation culture and working practices of academic and support staff alike.

Entitled the Charles Sturt University Degree Initiative (CSUDI) the process necessitates a *shared sense of responsibility* for planning the *total* student experience amongst those who coordinate and teach a course to create a distinct “CSU student experience” culminating in “CSU graduateness”. In a nutshell the aim is for CSU undergraduates, in addition to an in-depth understanding of their chosen disciplines

and professions, to have their studies underpinned with integrated and embedded principles equipping them for the modern world.

Whilst the CSUDI is clearly the mechanism for the "student experience" to happen – unless the transformational *design-based approach to curriculum renewal* is truly collaborative, incorporates a wider vision, and a different approach, the concept of "graduateness" will not take place.

Keywords: student experience, engagement, equity, curriculum renewal

Introduction

This poster depicts the development of a design based approach to degree level curriculum renewal at CSU. To be introduced progressively to students from 2012, this approach integrates CSU's learning and teaching expertise with pedagogical innovation; to enhance the student experience. CSU is in the process of developing an integrated framework of design principles, course analysis processes, course exemplars and course approval processes. The design principles that will be integrated and embedded within the CSU approach are discussed below.

Content design principles

The disciplinary and professional knowledges that students engage with are influenced by the degree type and the degree purpose. The CSUDI wishes to embed the following engagement within each degree:

- The opportunity for international experiences and to develop an international perspective in their discipline or profession;
- An engagement with the responsibilities of global citizenship;
- The opportunity to develop cultural competence;
- The opportunity to engage meaningfully with the culture, experiences and histories of Indigenous communities;
- Understandings of financial, social and environmental sustainability;
- A firm understanding of ethics;

Innovative learning and teaching design framework

Each discipline area and degree have traditions and pedagogies that have developed within a particular culture. The curriculum renewal process seeks to influence that culture by creating a development framework that values (and adds to) the learning that our diverse students bring to their study. The ways that students will be supported include:

- Engagement in activities that foster web-based proficiency and innovative ways of learning.
- A supported transition into the first year of university; and thereafter throughout the undergraduate student experience;
- Employability and generic and transferable skills such as effective communication; analytical skills; critical and reflective judgment; problem-solving; team work; and time-management; Education based in practice;

This horizontal and vertical alignment is allowing a holistic understanding and therefore development of a course to take place. This has previously not been a wholly transparent process in a subject based approach. The increasingly diverse cohort profile and changing markets demands this approach and this aims to provide an increased equity of student experience and outcomes.

Teaching Teachers for the Future: Exploring the different interpretations, applications and experiences of TPACK

Ms Vilma Galstaun
University of Sydney

Ms. Shannon Kennedy-Clark
University of Sydney

Dr Lina Markauskaite
University of Sydney

Prof Peter Goodyear
University of Sydney

Ms. Shaista Bibi
University of Sydney

Abstract and Symposium Plan

As part of the national Digital Education Revolution (DER) all pre-service teachers need to develop both understanding and competency in embedding information and communication technologies (ICTs) into the content areas through a TPACK framework (Department of Education, 2008). A Government scoping study indicates that the most common forms of ICT currently used in classrooms are PowerPoint and basic Internet searches (Education Services Australia, 2010). These forms of ICT do not make best use of the potential learning possibilities of ICT. This project is aimed at developing the technological pedagogical content knowledge (TPACK) of pre-service teachers via sustainable integration of ICT in pre-service teacher education programs for both primary and secondary teachers.

Each of the speakers will discuss their understanding of TPACK and their areas of research:

Vilma Galstaun will provide a broad overview of curriculum re-design using a TPACK framework at the University of Sydney

Shannon Kennedy-Clark will provide examples of embedding ICT into History and Science units of study across the pre-service teacher degrees and will report on survey findings on pre-service teachers' TPACK.

Lina Markauskaite and Peter Goodyear, Yael Kali, Agnieszka Bachfischer in the paper "Unpacking TPACK: exploring knowledge in eLearning design teams" will discuss some findings from a study of eLearning design teams, in which they applied some key TPACK concepts for researching teams' collaborative design practices and knowledge. The symposium will commence with a discussion, which will be followed by interactive presentations by each of the speakers and will conclude with a final discussion that synthesises the main ideas raised by the audience and presenters. The symposium is intended to generate discussion and feedback from the audience. All of the presenters will address several shared questions: a) how is TPACK being interpreted, b) how is ICT being embedded to develop technological, pedagogical and content knowledge in a subject-specific context, c) how is ICT being embedded into the Faculty and graduate standards, and e) how do Faculties sustain this type of systemic change?

Shaista Bibi and David Ashe will discuss a knowledge in pieces theoretical framework which may allow a more detailed exploration of the nature of TPACK. Knowledge in pieces was developed as a theory to explain the nature of physics knowledge and has since been used to explore diverse aspects of knowledge such as epistemology, pedagogy and transfer. This theory may help in gaining a better, more nuanced understanding of how different knowledge elements are integrated.

Exploring the Use of Audio-Visual Feedback within 3D Virtual Environments to Provide Complex Sensory Cues for Scenario-Based Learning

Michael Garrett
Edith Cowan University

Mark McMahon
Edith Cowan University

The continuous quest for ever increasing fidelity in 3D virtual worlds is running parallel to the emergence and adoption of low-cost technologies to implement such environments. In education and training, complex simulations can now be implemented on standard desktop technologies. However, such tools lack the means to represent multisensory data beyond audio-visual feedback. This paper reports on a study that involved the design, development and implementation of a 3D learning environment for underground mine evacuation. The requirements of the environment are discussed in terms of the sensory information that needs to be conveyed and techniques are described to achieve this using multiple modes of representation, appropriate levels of abstraction and synesthesia to make up for the lack of tactile and olfactory sensory cues. The study found that audio-visual cues that used such techniques were effective in communicating complex sensory information for novice miners.

Keywords: synesthesia; human-computer interaction; serious games; engagement, e-learning

Introduction

Explore any website and it is immediately apparent that text and graphics and, to a lesser extent, audio dominate as the primary modes of digital information. Such approaches, however, are inherently limited in the nature of the information that they convey. In e-learning settings, where concepts such as authenticity and situatedness are often cited as powerful means to promote transfer of learning (Brown, Collins, & Diguid, 1989), then the abstract nature of much media becomes increasingly problematic. As technologies mature and 3D representation becomes increasingly easy. 3D game engines are providing effective alternatives to workplace learning because of their low cost and limited need for programming skills to develop rich applications (Garrett & McMahon, 2010).

One way in which 3D game engines frequently provide sensory cues is through the use of a Heads Up Display (HUD). While a very common approach to information presentation, HUDS have recently come under criticism for the abstract nature of their representation of information:

> Many elements found on a typical HUD are there not out of necessity, but out of convention; they represent a sort of "info overkill" that, for the vast majority of players, has no impact on gameplay at all. For every piece of information you offer the player, ask, "Is this information essential to the game experience?" In doing so, you might find that you don't need to bombard the player with quite as much data as you once thought you did. (Wilson, 2006).

As a potential refuge of lazy design, it is certainly true that HUDs are not always necessary. It can also be argued that not all authentic information needs to be represented within a given simulation. Factors that relate to aspects of the learning such as the nature of the task to be performed and the feedback inherent within that may need to be represented with a high fidelity, however this is not true of all situations and hyperfidelity may be as disorientating when there are specific learning goals as hypofidelity may be inadequate (Stone, 2008).

However, the continued existence of HUDS highlights that even in the most realistic 3D environment there are some sensory cues that are extremely hard to replicate. Since the 1970s the dominant mode of computer interaction has been through a keyboard, with typical output in the form of video on a monitor and speaker-based audio. Despite the introduction of the mouse and more recently surround sound, the standard computer interface has varied little over the years. With that in mind, consideration needs to be given to how existing technologies can best represent the multisensory feedback that is so relevant to real-world decision-making.

Modes of sensory feedback

There have been various attempts to augment audiovisual experiences with other sensory cues. Some, such as the notorious ‘Smell-O-Vision’ of b-grade cinema, later refined as ‘Odorama’ by director John Waters, can best be viewed as gimmicks that are used for comedic or promotional purposes (Gilbert, 2008). The sense of taste is even more problematic in that any taste ‘interface’ is likely to be quite invasive, which may explain the paucity of examples of such interaction modes in traditional media and interface research.

Haptic interfaces on the other hand have fared far better. From early manipulators, through to desktop systems, the history of haptic devices is one of continuous refinement and development (Stone, 2000). Their value lies in their capacity to provide kinaesthetic and tactile feedback that allows the user to experience both texture and movement associated with authentic tasks (Hayward, Astley, Cruz-Hernandez, Grant, & Robles-De-La-Torre, 2004). As such they are highly suited to a range of training scenarios which require the representation of physical motion, force feedback and touch at a high level of fidelity. The cost of such systems are also coming down, with, for example, the Nintendo Wii which uses accelerometers and cameras in its ‘wiimote’ to register motion and the Novint Falcon, which operates as a haptic mouse providing force feedback, entering the consumer marketplace. However the range of software for which these devices have drivers is still somewhat limited.

In most cases, a developer is required to represent such forms of feedback using other means. While the sensations of sight and hearing may seem somewhat removed from those of taste, touch and smell, research into synaesthesia suggests that specific senses may be stimulated by alternate modes of representation.

Pierce (1911) noted this phenomenon in a range of specific cases including, ‘colored hearing’ where certain French vowel sounds were perceived as belonging to a certain color. Put simply, it is the crossover of sensation, where certain sensory stimuli are perceived by other senses. For the most part, this has been considered something of a rare neurological phenomenon experienced purely at an individual level (Harrison, 2001). Some experiments, however, such as the classic Booba/Kiki effect by Gestalt psychologist Wolfgang Köhler, suggest that certain visual cues are quite salient in terms of how shapes are perceived as sounds. In examining two irregularly shaped objects (Figure 1) 95-98% of participants select the left angular shape for Kiki and the right rounded shape for Booba (Ramachandran, 2004).

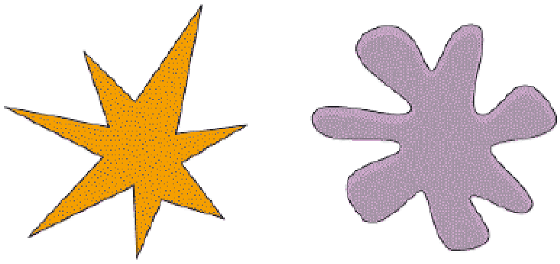

Figure 1. Kiki (left) and Booba (right)

Ramachandran (2004) suggests that a natural link is formed by the circular shape of the mouth when making sounds such as ‘ooh’ in combination with the softer sound of ‘b’ to the more rounded shape of Booba compared to the more acute sound of‘eeh’ and ‘k’. Similarly, the shapes of the objects are more closely aligned with their counterpart consonants. In any case,it is evident that there are some predictable relationships between concepts that are represented across a range of sensations that could prove useful for game interfaces.

Alternative and multimodal sensory representation

Synaesthetic cues have been used in games in informal ways for a long time. Weir (2004), for example, notes how music can enhance the tactile experience of a game, using the case of a dark first person shooter game where bumping into a metal chain hanging from the ceiling could play a sinister chord, the pitch of which modulating as the chain swings. The Gears of War game series (Epic Games, 2006) also demonstrates this in the way that health is represented. The physical sensation of poor health cannot be fully replicated within the game so instead the character grunts when he is hit and, at a more abstract level, the periphery of a screen turns blood red and vision is obscured the more damage your character receives. The blood motif is a reminder in that sensory information has the potential not only to be provided in the form of informational cues but also at a higher level of abstraction through metaphor. Iconography is one primary means of achieving this. Icons can exist at a variety of levels of representation. Preece (1994) identifies the following modes in descending order of concreteness:

- Resemblance Icons
- Exemplar Icons
- Symbolic Icons
- Arbitrary Icons

While resemblance icons accurately represent the concept to be communicated (e.g. a ‘rocks falling’ road sign), exemplars provide a specific instance (such as a knife and fork representing the availability of a restaurant). Symbolic icons are readily identifiable but may not actually be a specific example. A fractured wine glass, for example, may denote fragility even though it may not actually be glass that is fragile. As the name suggests, arbitrary icons do not have a direct meaning. In computer terms, for example the USB icon does not directly map onto a recognizable concept, just as the biohazard icon operates at an equally high level of abstraction. While the USB icon’s three-pronged form seeks to mimic the physical process of plugging a device in and transferring data, it could be argued that the biohazard sign, while deliberately designed to be ‘memorable but meaningless’ (Cook, 2001), operates synaesthetically because the combination of soft circular imagery and sharp points where they intersect provide resemblance to molecular structures with a sharpness suggestive of penetration (Figure 2). As such it is a very relevant sign for devices like needle disposal bins.

Figure 2. Biohazard Symbol

Audio also operates at similar levels of abstraction. Audio can function in both direct and ambient ways to achieve a range of functions such as:

8. Localization, which lets you know where you are
9. Sonification, turning information into sounds
10. Ambient effects, to add depth and realism
11. Sensory substitution, which replaces one sensory stimulus with a sound
12. Annotation and help, to guide the user (Ardito, Costabile, De Angeli, & Pittarello, 2007)

Sensory substitution in particular operates at a synaesthetic level to reproduce other physical stimuli through audio. It has found widespread acceptance, especially in the domain of design for the disabled such as those with visual impairments (Proulx, 2010). There is therefore a range of audiovisual cues that can be used to enhance the types of feedback in 3D serious game environments where direct representation is not possible.

Such interface features need not be used discretely. Media Richness Theory argues that providing multiple cues including communicative modalities through rich media can facilitate shared understanding. Research into multimodality suggests that multiple channels for information delivery and presentation assist in the sense-making process in learning (Ritterfeld, Shen, Wang, Nocera, & Wong, 2009). Proponents of serious games based education have successfully utilised such an approach to convey the impression of severe weather conditions in a levee patroller training application (Houtkamp, Schuurink, & Toet, 2008) and facilitate memory and navigation training in virtual representations of real world environments (Larsson, Vastfjall, & Kleiner, 2001), for example. Consideration, therefore needs to be given to how both audio and visual cues can represent the full range of sensory information required to effectively complete tasks in serious games that that make the best use of the affordances of those modes. In particular consideration of the synaesthetic quality of those cues and the potential for multimodal representation may greatly assist in providing effective interfaces for such environments.

About this study

Alternative and multimodal representation was explored through the design, development and implementation of a problem-based learning scenario, using 3D game technologies. An industry partner was selected to provide a real world context in which to situate the design of the simulation environment. Dominion Mining was selected for this purpose with a focus on their Challenger underground mining facility located in South Australia.

Dominion had acknowledged that a computer-generated simulation environment could be used to conduct emergency evacuation training within a virtual representation of the Challenger underground mine. Such a training platform could be used to develop knowledge of Dominion's existing evacuation procedures which could be transferred and applied within the real world mine during an emergency. Dominion's existing procedures direct personnel to locate a refuge chamber in the event that an evacuation is required. Refuge chambers are self-contained steel structures that are capable of accommodating multiple miners with independent power and oxygen supplies which are utilised in the event that the supply of these essential services from the surface is interrupted. The Challenger facility has a number of these refuge chambers situated in specific locations in order to provide coverage for the entire mine in the event that an emergency evacuation is initiated.

In order to assist personnel to reach a refuge chamber safely in the event that smoke, excessive dust, or noxious fumes are present within the mine, personnel are outfitted with a self- rescuer, which is a portable gas mask which supplies oxygen via a controlled chemical reaction. Self-rescuers have a finite supply of oxygen which is depleted at a rate proportional to how quickly and deeply the individual who is wearing it is breathing. Dominion protocol mandates that during an emergency, personnel are to equip their self-rescuers if their breathing is obstructed, and that personnel should minimise the amount of physical effort they expend on the way to a refuge chamber in order to prolong their oxygen supply.

Thus, during an emergency evacuation, personnel need to reach a refuge chamber as quickly and efficiently as possible in order to maximise the duration of oxygen supplied by their self-rescuer. To this end, personnel have to be aware of the levels of physical effort required to traverse the mining environment and the effect that this has on their breathing rate and subsequent oxygen consumption in order to be able to evacuate effectively during an emergency underground.

Development of the simulation environment

Given the objective of developing knowledge of Challenger's emergency evacuation procedures, the simulation environment was designed in accordance with the Simulation, User, and Problem-based Learning (SUPL) design framework (Garrett & McMahon, 2009), whereby learning was situated within problem-solving activity with the goal of facilitating learning transfer.

The simulation was constructed using the DirectX-based DX Studio development suite (http://www.dxstudio.com) which provided an integrated platform for the development and configuration of necessary content. The development suite consisted of a mouse and keyboard operated GUI which enabled content to be imported, arranged, configured, and previewed dynamically as changes and modifications were made. In this manner, a virtual representation of the mine was able to be rapidly prototyped which was desirable given the available time frame for development and financial constraints imposed by the study.

The simulator, designated FUMES (Fire in Underground Mining Evacuation Scenario), was developed in this manner in order to expose users to a three-dimensional, simulated representation of an underground fire emergency situated within a section of the Challenger mine. In order to facilitate the development of knowledge that could be utilised during a similar emergency in the real world mine, users were tasked with evacuating to a refuge chamber within the virtual mine in accordance with Dominion's existing evacuation procedures. To this end, users were provided with the ability to walk, run, and orientate themselves from a first person perspective and could equip a virtual self-rescuer in order to safely negotiate simulated smoke. User interaction was facilitated via a standard mouse and keyboard based setup common to many First Person Shooter (FPS) games, with the mouse being used to control orientation, and the keyboard handling movement and the use of the self-rescuer.

The virtual mining environment itself was modeled using AUTOCAD architectural data from the Challenger mine supplied by Dominion such that FUMES could accurately depict the spatial characteristics of the real world mine in three dimensions. The speed at which users could be expected to be able to walk and run, the resultant physical effort required to do so, and the effect this had on oxygen consumption when using the self-rescuer were also modeled as authentically as possible using information supplied by subject matter experts at Challenger.

Depiction of sensory modalities

Developing an understanding of the significance of movement, physical exertion, and self-rescuer oxygen consumption during an emergency evacuation of the Challenger mine necessitated the representation of these concepts, their characteristics, and interrelationships within the simulation environment. The nature of these concepts within the real world mine was identified via consultation with subject matter experts at Challenger in order to inform the design of the simulation environment in this regard, as detailed in Table 1.

Table 1. Concepts relating to movement, physical exertion, and self-rescuer oxygen consumption

Concept	Characteristics	Interrelationships
Movement	Personnel can remain stationary, walk, or run within the mining environment.	Remaining stationary requires a low amount of physical exertion. Walking requires a moderate amount of physical exertion. Running requires a high amount of physical exertion.
Nature of the terrain	The underground mining terrain can be level or on a slope.	Traversing level terrain requires the least amount of physical exertion. Traversing downward sloping terrain requires more physical exertion than level terrain. Traversing upward sloping terrain requires more physical exertion than downward sloping terrain.
Physical exertion	The amount of effort required to conduct physical activity	The extent of physical exertion is proportional to breathing rate
Breathing rate	The frequency at which personnel are breathing	The frequency of breathing is proportional to the rate at which oxygen is consumed in a self-rescuer
Self-rescuer oxygen consumption	The rate at which the finite oxygen supply provided by the self-rescuer is consumed	

Given the technical capabilities of standard desktop computer hardware, representing the concepts detailed in Table 1 necessitated the use of visual and auditory feedback to approximate the sensory information which would be implicitly available within the real world mining environment. Table 2 details the manner in which the feedback representing movement, physical exertion, breathing rate, and self-rescuer oxygen consumption was represented within the simulation environment to this end.

Table 2. Representation of movement, physical exertion, breathing rate, and self-rescuer oxygen consumption using visual and auditory feedback

Feedback	Representation	Details
Movement	Auditory cues for footsteps.	Sound effects depicting walking or running on gravel in response to user movement
	Visual cues for movement speed	Icon representing user movement speed (stationary, walking, or running)
Nature of the terrain	Visual cues for inclination of the terrain	Icon representing inclination of the terrain that the user is moving over (level, uphill, or downhill)
Physical exertion / breathing rate	Auditory cues representing breathing	Sound effects depicting breathing at different rates depending on the current extent of physical exertion.
	Visual cues indicating the user's current physical exertion	Animated icon depicting a heart which beats more rapidly as physical exertion increases.
Self-rescuer oxygen consumption	Auditory cues representing breathing with a self-rescuer	Standard breathing sound effects are replaced with those of breathing with a self-rescuer

The visual icons described in Table 2 for representing movement speed, inclination of the terrain, and physical exertion were collated into a two dimensional interface which was rendered along the bottom of the screen, as detailed in Figure 3. Tables 3, 4, and 5 denote the states these icons could assume in order to represent movement speed, inclination of the terrain, and physical exertion as the user moved throughout.

Figure 3. Screen-shot from the simulation environment, with two dimensional icon interface rendered along the bottom edge of the screen

Table 3. Icons used to represent movement speed within the virtual mine

Concept	**Icon states**					
Movement speed		Statio nary	Walkin g			Running

Table 4. Icons used to denote the inclination of the terrain within the virtual mine

Concept	**Icon states**					
Inclination of the terrain		Level sloping terrain	Downw ard sloping			Upward sloping

Table 5. Animated icon used to represent physical exertion within the virtual mine.

Concept	Icon states		
Physical exertion	 Animated heart beats slowly for low physical exertion	 Animated heart beats moderately for moderate physical exertion	 Animated heart beats quickly for high physical exertion. Additional text also denotes high physical exertion

Movement, inclination and physical exertion were considered key to the training outcomes for this scenario and the above icons were supplemented with five further status icons that existed as a single toggle on/off. They were:

- The self-rescuer, which is lit when the user is wearing it. This icon reinforces the fact that breathing apparatus is in use and therefore the user has a limited level of oxygen available
- A walkie-talkie, which is lit when the user is receiving verbal instructions via audio
- A ladder, which clearly marks whether an escape shaft is in the immediate vicinity
- A cap lamp, which combines with the simulated light within the scenario to reinforce whether it is switched to high or low intensity
- Stench gas. An onion odour is released into the mine when noxious gas is detected to remind the miners to use self-rescuer equipment

The first four of these operate at quite a clear level of resemblance. The second is inherently synaesthetic in that it seeks to replicate an odour in a visual form. Ironically, this level of abstraction is carried through into the mine itself because many poisonous gases that can be released during the mining process are in fact odourless and colourless. In all cases, multimodality was used to enhance the icons. The first three were visually represented within the scenario itself while the final was supplemented with an audio cue.

In order to reinforce the concepts detailed in Table 1, auditory cues were also implemented to complement the icons representing movement speed and physical exertion within the simulation environment. Auditory cues depicting footsteps walking and running over gravel were played in response to user movement through the virtual mine. These were played concurrent to additional auditory cues which depicted breathing both with and without a self-rescuer, with relaxed breathing sounds utilised where the user's physical exertion was low, and rapid breathing sounds utilised where the user's physical exertion was high. A rapid beating heart auditory cue was also utilised in the event that physical exertion was high in order to reinforce the user's heightened level of physical activity.

Results

The feedback mechanisms described in Table 2 were evaluated in the resultant product FUMES in order to determine their effectiveness to approximate real world sensory information and facilitate an understanding of movement, terrain inclination, physical exertion, and self-rescuer oxygen consumption during an emergency evacuation.

A total of 41 participants comprised of personnel with varying levels of experience at Challenger were tasked with completing three emergency evacuation scenarios within FUMES in which they were tasked with safely reaching a refuge chamber in accordance with Dominion's existing emergency evacuation procedures. The user's starting position, the location of the fire, and the severity and spread of the resultant smoke varied in each of the three scenarios such that the scenarios became progressively more demanding. At the end of each scenario, the user was provided with feedback in relation to their performance, detailing how long they took, how far they traveled, how much effort they exerted, how much oxygen they consumed, and whether or not they took the best route to the refuge chamber, with this information being recorded in a database.

Analysis of the performance measures recorded in the database generally suggested that users were able to effectively perform the evacuation procedure within the virtual mine, with 100% of users successfully able to reach a refuge chamber in the first scenario, 85% in the second scenario, and 43% in the third. While this did demonstrate a general decline in performance across the series of three scenarios, this could be attributed to the deliberate design decision to make the second and particularly third scenarios more challenging in terms of the user's initial proximity to the fire, the severity of smoke, and the subsequent effects this had on visibility within the virtual mine. This was reflected in the data recorded in the database denoting the time taken and effort exerted by participants, which tended to be greater during the second and third scenarios, on average. While the database data did not provide a great deal of insight in relation to whether the feedback mechanisms provided within FUMES were effective in approximating real world sensory information, it did suggest that this sensory information was at least sufficient enough to allow participants to perform Dominion's emergency evacuation procedure within a virtual representation of the Challenger mining environment.

In order to determine how effectively the feedback mechanisms approximate real world sensory information that was necessary during an emergency evacuation procedure, participants were required to complete a questionnaire in relation to their experience at the conclusion of the third scenario. More detailed interviews were also conducted with five of the participants.

Movement

Questionnaire responses indicated that users could discern their movement speed during the simulation, with 82% of participants agreeing or strongly agreeing that they were aware of how fast they were moving within the virtual mining environment. This suggested that the icon used to represent movement speed and the auditory cues which represented footsteps were sufficiently adequate to allow the user to know the difference between when they were stationary, walking, or running.

Inclination of the terrain

Participants indicated that they were aware of the inclination of the terrain they were traversing, with 75% of participants agreeing or strongly agreeing that they knew whether they were moving uphill, downhill, or over a level surface within the virtual mine. These responses implied that the icon used to denote changes in the inclination of the terrain was effective in informing the user as to the nature of the mining environment in this regard.

Physical exertion

Participants demonstrated an awareness of their physical exertion during the simulation, with 79% of participants agreeing or strongly agreeing that they knew how much physical effort they were expending within the virtual mining environment. Interview responses reflected this awareness, with participants making repeated references to the role of the auditory cues which represented breathing in informing them as to the extent of their physical activity. This suggested that the animated heart icon depicted in Table 5 in conjunction with the aforementioned auditory cues were effective in establishing the user's level of physical activity within the simulation environment.

Awareness of relationships

Questionnaire responses further indicated that participants understood the effect that movement speed had on physical exertion, with 90% of participants agreeing or strongly agreeing that running required more physical effort than walking within the simulation. Furthermore, participants were also aware of the effect that the inclination of the terrain had on physical exertion, with 87.5% of participants agreeing or strongly agreeing that moving up an inclined surface required more effort than moving down one, and 95% of participants agreeing or strongly agreeing that the physical effort they expended was affected by the slope of the terrain. These responses demonstrated that participants were successfully able to acknowledge movement speed and the inclination of the terrain as factors which affected physical exertion within the simulation environment. This indicated that the participants were able to establish a connection between the feedback mechanisms used to denote movement speed and the inclination of the terrain, and those used to represent their physical activity.

Additionally, participants indicated that they understood the relationship between physical effort and self-rescuer oxygen consumption, with 77% of questionnaire respondents agreeing or strongly agreeing that they had to be aware of their physical effort when using their self-rescuer, and 80% of participants agreeing or strongly agreeing that the physical effort they expended affected the rate at which oxygen was consumed. Interview responses again predominantly referenced the auditory cues used to represent breathing in delineating the relationship between physical exertion and self-rescuer oxygen consumption. All interviewees also stated that the relationship between movement speed, physical effort, and oxygen consumption was clearly demonstrated within the simulation environment. This provided evidence to indicate that the feedback mechanisms used to delineate movement speed, the inclination of the terrain, and the subsequent effects on physical exertion and self-rescuer oxygen consumption were effective in developing an understanding of these concepts and their interrelationships within participants as a result of using the simulation environment.

Findings and conclusion

Responses from participants indicated that the simulation environment provided a clear sense of movement speed, the inclination of the terrain, and physical exertion. This information was effectively conveyed via a combination of visual and auditory feedback which was used to approximate sensory information which would be implicitly available within the real world environment being represented. These feedback mechanisms were deemed effective enough to facilitate an understanding of the relationships between movement speed, terrain inclination, physical exertion, and self-rescuer oxygen consumption which could be applied during an emergency evacuation of the real world Challenger mining environment.

While the use of such cues do impact on the fidelity of the environment and therefore potentially the transfer of learning that can occur, it was evident in this study that learners were quickly able to formalize the meaning of the visual an auditory stimuli in a manner that facilitated their performance in the simulation. It is a tangible reminder that even the most abstracted symbols can be powerful and useful performance cues once their meaning is internalized by the end user. One interesting finding from the study was that while the techniques identified here proved effective cues for mine evacuation, some subtle real-world cues that were not represented within the simulation were seen as a limitation by the participants. For example, the crude depiction of cabling in the interior of the mine was seen as a limitation for those participants who found value from it as a tool for navigation and identifying waypoints within the mineshaft. Also, one participant argued that in an evacuation scenario he would also use the real-world tactility of the tunnel wall to guide his movements, particularly where visibility could be hindered by smoke. The first of these is something that could be remedied with a higher level of fidelity in the visual representation of the cabling. The latter could either be represented using a haptic mouse or, given the success of the use of synaesthetic cues in this study by providing collision feedback in the form of an audible brush against the rock wall.

Despite such limitations, therefore, it is evident that approximating complex sensory stimuli using visual and auditory feedback can be effective in 3D training scenarios using simple desktop technology. Such stimuli may be depicted using multiple modalities, represented at variety of levels of abstraction, and using sensory substitution to provide a synaesthetic experience for end users.

Student perspectives of eportfolios: Change over four semesters

Philippa Gerbic, Lyn Lewis & Norasieh Md Amin
Auckland University of Technology
New Zealand

Universities are currently under pressure to provide evidence of graduate attributes and at the same time to improve learner engagement. Eportfolios and their associated pedagogies have the potential to support students' learning and development and to provide evidence of their progress against standards or attributes. Research reports about eportfolio introductions provide guidance on this new technology however student voices are underrepresented and most studies occur over a single course. This paper reports early data from a three-year longitudinal study of students in a Bachelor of Education. Survey results across four semesters, which included first-time users in each semester, indicated (1) increasing recognition of the eportfolio for learning in the areas of evaluation, reflection on the learning process, and keeping track of learning experiences and (2) decreasing concerns about using the technology and technology as a barrier. There were also a steady increase of enthusiasm and positive feelings and a decrease in feelings of uncertainty, confusion, anxiety and negativity.

Keywords: electronic portfolios, longitudinal research, Mahara, student perspectives

Introduction

For some time, university graduates have been able to provide evidence of their degree capabilities solely through their university qualifications. Now, contemporary professional, and workplace communities and other stakeholders exert greater pressure on universities for more accountability (Clark & Eynon, 2009) as they increasingly demand graduates who can evidence their employability skills. This is now also well recognised within government policy contexts (Hallam, Harper, McGowan, Hauville, McAlister & Creagh , 2008). Universities must establish how best to respond to these demands, which are somewhat summative in nature while, at the same time, developing more personalised forms of learning which engage their learners and support their development as reflective professionals and confident and autonomous learners (Chau & Cheng, 2010).

Eportfolios have been identified as a technology which has the potential to benefit 21st century models of learning, teaching and assessment (JISC, 2008). While eportfolios bring digital advantages such as portability and flexibility, their use for learners also involves changes of habit, not only regarding the technology but also the accompanying pedagogy. This raises challenges for tertiary teachers in terms of creating an engaging learning environment where students must not only understand the technology but, more importantly, its role in their learning and development.

The purpose of this paper is to present part of a larger project which is investigating student perspectives of eportfolios over three years. We present and discuss some early results from four semesters of questionnaire data. Perspectives over time are especially valuable for technology innovations because they can document change, growth and development, if any. A common theme in the eportfolio research literature is the impact of the eportfolio technology itself on the student experience. We are interested in the ways in which contextual factors in the learning environment not only influenced student perspectives of using the eportfolio technology but also their learning.

Eportfolios and Learning

Stefani, Mason and Pegler (2007) refer to portfolios as "another tool in the e-learning armoury" (p.7) and argue that the key concept is the potential of a portfolio approach to learning rather than any digital characteristics. The elasticity and flexibility of the eportfolio as a personal learning space which can have different roles over the lifespan leads them to identify the transformational potential of the technology, however, they note that the technology is still immature and widely and variously defined. We have adopted the JISC (2008) definition of an eportfolio because it seeks to integrate the technology with pedagogical processes:

> *"An eportfolio is the product, created by the learner, a collection of digital artefacts articulating experiences, achievements and learning. Behind any product or presentation, lie rich and complex processes of planning, synthesising, sharing, discussing, reflecting, giving, receiving and responding to feedback. These processes referred to here as 'eportfolio-based learning' - are the focus of increasing attention, since the process of learning can be as important as the end product" (p.6).*

The JISC (2008) definition also attempts to conceptually connect the process and product roles of eportfolios and there is some support for this. In Chau and Cheng's (2010) study of first time university eportfolio users, most students (and teachers) saw the eportfolio as supporting both the development of a product and the learning process. However, the researchers highlighted the tension between these two aspects and argued that the pressure to demonstrate criteria (such as university graduate attributes) could lead to 'clone' (p. 940) performances and suppress individuality and creativity which could be fostered when eportfolios were used in a more personalised fashion.

Eportfolios are generally located within a constructivist perspective (Stefani, Pegler & Mason, 2007; Barrett, 2005) and their pedagogies often feature reflective and evaluative approaches to professional development and learning (Lin, 2008). In the case of teacher education, the concept of the reflective practitioner is a professional and cultural cornerstone, and there is widespread acknowledgement in the literature of the use of portfolios to develop 'habits of reflection and analysis' (Zeichner &Wray, 2001, p.614). However, in some cultures and disciplines (Vernazza, Durham, Ellis, Teasdale, Cotterill & Scott, Thomason, Drummond & Moss (2011) students have found reflection to be a difficult process and Orland-Barak (2005) observes that the quality of the reflection is not necessarily influenced by the portfolio, and other processes such as collaborative discussions, can produce higher levels of critical reflective thinking. Eportfolios are also valued for their ability to provide more authentic forms of learning and assessment (Emmett, Harper & Hauville, 2006) although the role of experiential concepts and approaches to learning has received sparse attention in the eportfolio literature.

The literature on eportfolios emphasizes the potential of the technology to be transformational. However, the research into student perspectives indicates that there is often a gap between institutional and teaching visions and the reality of student experiences. Some studies have reported positive student perspectives. Lin's (2008) one year study of 38 student teachers reported , from survey data, positive attitudes to eportfolios and identified benefits for learning such as improved self assessment and reflective skills, enhanced organisational, synthesis and ICT skills, and the value of learning through peer collaboration. However, the students were enrolled in an ICT course where the focus of the paper and its learning and assessment strategies provided a rationale for the eportfolio for students. Bolliger and Shepherd's (2010) survey-based study of 40 students over two semesters also reported positive perceptions from students around the value of goal setting, evaluating progress, reflection and communication with peers and the teacher. Their students were engaged in postgraduate study and were distance students and these factors may have influenced their perceptions. Ring and Foti's (2006) study of 1025 student teachers identified benefits including raising consciousness of professional teaching standards, addressing the challenge of explaining the connection between their teaching practice and the standards and making links between theory and practice. They claimed that there was a shift in responsibility to their students and that eportfolios were transformational because students were engaged in new learning processes which involved making decision about their practice and then justifying and explaining them against standards. While the US university context has its own special characteristics, the findings of this study are noteworthy because of the size of the sample, and because this was a longitudinal study over four years.

Some studies have illustrated negative student views of eportfolios. One widely identified issue is frustrations around learning to use the technology (Lin, 2008; Singh & Ritzhaupt, 2006, Tosh, Light, Fleming & Haywood, 2005). The other commonly mentioned issue is demand on student time which is not only related to using the technology but understanding the associated pedagogy (Lopez-Fernandez & Rodriguez-Illera, 2009), especially regarding learning and assessment activities, particularly reflection (Vernazza et al, 2011), but also the role and value of collaboration (Carroll, Maukauskaite & Calvo 2007). Singh and Ritzhaupt (2006) identified student resistance to the eportfolio arising from insufficient support and training, lack of understanding and buy-in from their teachers, an annual charge and a requirement to produce an eportfolio before graduation. Negative student perceptions have also been identified by Tosh, Light, Fleming and Haywood (2005) who identified buy-in, workload and inadequate assessment return, challenges in learning to use the technology and student motivation and engagement. Student opinions about the eportfolio were ambivalent in that while they did not think that the eportfolio was an obstacle in their study they did not think that working with it had assisted them in the course. The findings of this research are notable because this was a three-year study which followed the planned and phased introduction of eportfolios in one British and two Canadian universities.

Some studies have investigated psychological factors related to eportfolios. Researchers report that students may feel challenged and overwhelmed and express anxiety, confusion and uncertainty about the purpose and audience for the eportfolio (Lin 2008). Other student concerns are anxiety about the scope and nature of tasks, the absence of models, their general lack of preparedness for developing a creative and personal work (Darling, 2001). Also identified are teachers' expectations and requirements, keeping track of paper placement reports and then getting them into the eportfolio (Pincombe, McKellar, Weise, Grinter, & Beresford, 2009). In a relatively large study for this field (364 students), Tzeng (2010) highlighted the important role of student attitudes i.e. beliefs about the advantages of the technology and identified these as more important than perceptions of value around costs and benefits, usefulness and institutional support. Many studies endorse the importance of the broader context for the eportfolio in terms of the learning design and the role of the teacher in developing positive attitudes and addressing concerns and anxieties.

A range of methodologies have been used to investigate student perspectives of eportfolios with much of the research being insider research in the nature of case studies carried out by enthusiasts (e.g. Lin, 2008; Pincombe et al, 2009). Surveys have been carried out, however the numbers of participants have often been less than 100 students, with greater numbers of students being less common (Tzeng, 2010; Parker et al. 2009; Singh & Ritzhaupt, 2006; Tosh et al, 2005). With the exception of Tosh et al (2005), and Ring and Foti (2006), most of the studies we have located gathered data from a single semester and from a single class (e.g Lin, 2008) and did not survey students from a range of courses. Bolliger and Shepherd's (2010) results were based on data across two semesters and they observed that 'it was not clear how time would influence students' perceptions (p. 310). Housego and Parker (2009) have noted the limited availability of studies of longitudinal use of eportfolios and student perspectives. We argue that the area of development of student views of eportfolios over time is under-researched. This research study seeks to address this gap in eportfolio knowledge by investigating student perspectives in a Bachelor of Education (Primary) programme across three years. The outcomes of this research will contribute (1) to pedagogical and institutional knowledge about eportfolios and (2) to better understanding of issues involved in students' adaption to new technologies.

The Research Study

The research discussed here is part of a larger study which was described at the ascilite 2009 conference (Gerbic, Lewis and Northover, 2009). The aim of the overall research is to investigate student experiences of eportfolios and their impact or otherwise on their learning. The research questions are:

1. How do students experience an eportfolio?

2. How does an eportfolio help students to learn?

3. What hindrances or challenges are there for students when they use an eportfolio in their learning?

Our intention is to investigate changes (if any) over time in student perspectives after the eportfolio is introduced. Part of the value of such a study is to consider the relationships between student changes of perception with the expansion of teacher understanding of the technology and the development of a responsive pedagogy. The project also enables us to see whether, with the passage of time, students can move past the technological and other challenges and become more confident learners with their eportfolios.

Context

The Mahara eportfolio (Eduforge, 2007) was first introduced into the B.Ed (Primary) programme in semester 1, 2009 to second year B Ed students and then extended into Years 1, 2 and 3 of the programme over the next 18 months. The eportfolio was initially embedded within the Practicuum programme where it where it was used by student teachers while they were in schools to reflect on their teaching experience. It was also used for goal setting and self appraisal against teacher graduating standards and was assessed. In Year 1, students were introduced to the eportfolio, using it formatively to support goal setting and reflection.

In 2010, the eportfolio was introduced into a Technology course where it was used as part of a learning assessment. For the first two semesters, there were technical issues with the eportfolio software but these have now abated and a variety of training approaches (workshops, online and printed materials, teacher modelling and peer coaching) have raised overall student comfort with the technology. The teaching team has remained the same for four semesters, however their understanding of eportfolios has significantly increased and they have continued to extend and incorporate authentic eportfolio tasks across the programme. Building student understanding of the role and value of the eportfolio in their development as professional teachers has been embedded within the programme as a significant and an ongoing activity.

Methodology

This study has been designed as a longitudinal study with the aim of building a picture of student perspectives over three years. Longitudinal research is a research design where (a) data are collected for each item or variable for two or more distinct time periods; (b) the subjects or cases analyzed are the same or at least comparable from one period to the next; and (c) the analysis involves some comparison of data between or among periods (Menard, 2002, p. 2). A longitudinal approach is useful for investigating the dynamics of change, growth and development over time (Cohen, Manion &Morrison, 2000) and to identify general trends. It is therefore valuable for investigating innovations such as eportfolios and their impacts on student learning. Longitudinal studies may include different participants over time. Here, for pragmatic reasons, we chose not to follow a single cohort of students, but used instead a rolling sample (Gorard, 2001). After the first semester, all classes using the eportfolio were invited to participate, and consequently, each semester, in addition to first time users, the sample included a proportion of students who had previously used the eportfolio and were likely to have completed a questionnaire.

We have adapted the questionnaire used in the Australian ePortfolio Project (Hallam, Harper, McGowan, Hauville, McAlister & Creagh, 2008). This had the advantage of being used in a relatively similar educational context, and had been rigorously developed and tested prior to its use. The resultant anonymous questionnaire comprised six closed questions, one open question and seven closed questions with space for students to comment. The questions covered a range of pedagogical and psychological issues such as benefits for learning development of professional skills, getting employment, challenges and outlooks. The project received ethical review and approval and recruitment and data collection was carried out by the researcher who did not teach the students and the research assistant. SPSS software was used to collate the questionnaire data and present it by semester and responses to open ended questions were coded using NVivo. The research team then carried out a descriptive analysis of trends.

Participants

Two hundred and sixty-eight questionnaires were completed over 4 semesters and by 86% of students enrolled in those classes. Details of the student participants are provided in Table 1 below. This shows the programme year of student study, and the number of students participating over the enrolled number. The arrow indicates the movement of that group of students in the following semesters. Across the four semesters, 145 students were initial users and 47 students had three semesters' experience. Across the four semesters, students were aged predominantly 25 years and under (58 – 79% across the four semesters) and were mostly female (81- 97% across the semesters). The percentage of students with a Web presence such as Facebook was high, with a range of 91 – 97% across the semesters.

Table 1: B. Ed (Primary) Questionnaire Participant Information

June 2009 ***(Semester 1)***	**November 2009** ***(Semester 2)***	**June 2010** ***(Semester 3)***	**November 2010** ***(Semester 4)***
Year 2(A)* 35/35 →	Year 2(B)** 26/30 →	Year 3(A) 25/28	
	Year 1(B) 38/40 →	Year 2(A) 38/40 →	Year 2(B) 22/30
		Year 1(B) 12/15 →	Year 2(A) 12/15
			Year 1(B) 50/70
			Year 3(A) 10/10
35 students	64 students	75 students	94 students

* (A) = first semester of the programmeyear
** (B) = second semester of the programme year

Results

We present selected results from four semesters of data. Because of the introduction to Year 1 students after the first semester, the results for semesters 2, 3 and 4 include first time users and it is only in semesters 3 and 4 that student perceptions are available from students who have used the eportfolio for three semesters. However, there was a high level of survey participation in each class (from 71 – 100%) so the data has captured a large proportion of the available student perceptions, rather than those of enthusiasts. These results have been considered in the light of key contextual factors associated with the eportfolio introduction. In semester 1, there were issues with the performance of the software and many of these continued into semester 2. As the semesters proceeded, software issues disappeared, and the stable and committed teaching team deepened their understanding of eportfolios and the importance of scaffolding activities to improve student understanding. Findings from the associated qualitative project provided more in depth student perspectives which were also fed into the eportfolio development and facilitated a responsive learning design process. Learning support options were widened to address variation in student competence and confidence in using eportfolios and the introduction and rationale for using eportfolios was continuously refined in response to student perceptions and teacher insights.

Role/Use of the eportfolio for learning

Students were provided with a list of possible outcomes of eportfolio use and then asked to indicate the extent to which the eportfolio had helped them in their current papers. Students' responses were measured using a 5-point Likert scale.

Providing a Place to Store Examples of Coursework

Figure 1 below shows the proportions of students and their levels of agreement and disagreement with the statement about storage. The graph shows an upward trend of students who agree and strongly agree. In semester 1, this combined proportion stood at 66% and by semester 4 had risen to 86% of the students. At the same time, the proportion of students who disagreed or strongly disagreed declined and by semester 4, no students expressed this view, although 13.3% of students were neutral on this issue. This trend direction is notable because just over half of the semester 4 students were using the eportfolio for the first time.

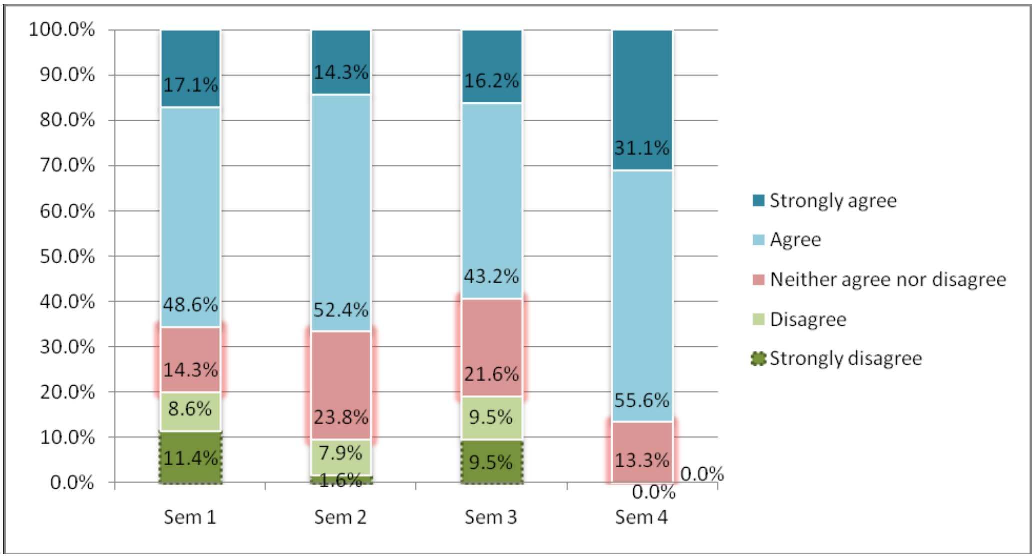

Figure 1: Providing a Storage Place

Allowing evaluation and reflection on the learning process

Figure 2 below shows the proportions of students and their agreement or disagreement with the statement. Across the four semesters the graph shows an upward trend of agreement. In semester 1, only 17.1% of students agreed with the statement and no students expressed strong agreement. By semester 4, 17.8% of students strongly agreed with the statement and when combined with students who agreed (66.7%) a total of 84.5% regarded this role positively and there was no disagreement or strong disagreement. This is a positive trend, especially, when taking into account the large number of first time users in semester 4. The high proportion of neutral students in semester 1 may be attributed to the technology issues. In subsequent semesters, neutrality levels may be affected by Year 1 students' views of their Practicuum reflections. This was their main use of the eportfolio and it was not assessed so it is possible that students may not have associated the reflections with their learning.

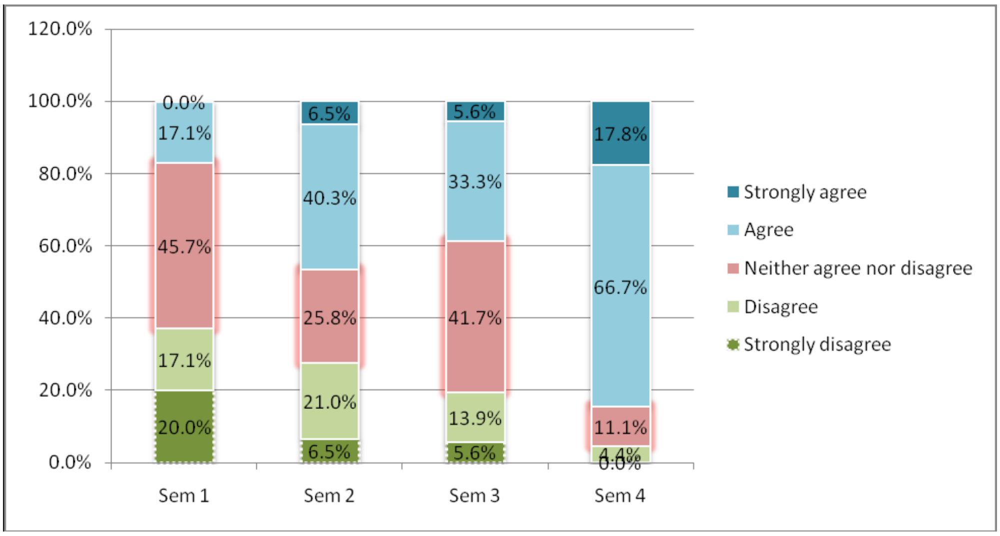

Figure 2 : Allowing evaluation and reflection on the learning process

Keeping track of learning experiences and reflecting on weak areas

Figure 3 below shows proportions of agreement and disagreement for this statement which focuses on the students' own progression rather than the learning process (above). There is a trend of increasing recognition by students of the value of the eportfolio for learning. In semester 1, 17% of the students agreed with the statement and by semester 4, 70.5% of students agreed and strongly agreed. The number of students who neither agreed nor disagreed remained somewhat static (31.9% - 34.3%) for the first three semesters and then decreased slightly to 23.9%. This may reflect the nature of assessment work and its direct links to the eportfolio from Year 2 onwards.

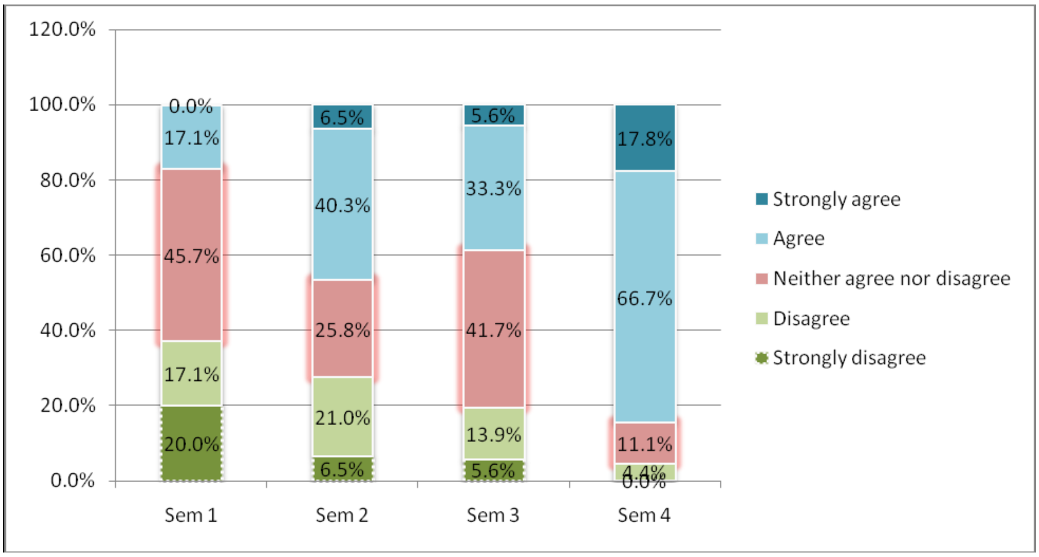

Figure 3: Keeping track of learning experiences and reflecting on weak areas

Helping students to become more effective and independent learners

Figure 4 below provides students' perceptions of their development as autonomous learners and here, data across the four semesters indicates a smaller increase in agreement. The proportion of students who agree and strongly agree rose from a modest 17.1% in semester 1 to 44% in semester 4. While the proportion of students who disagree/strongly disagree with the statement has reduced from 50% in semester 1 to 5.6% in semester 4, the proportion of students who are neutral has increased from 32.4% in semester 1 to 43.3% in semester 4. Possible influences on student perceptions here are likely to be related to the strongly scaffolded assessment tasks which students might not perceive to be building their capacity for independent learning.

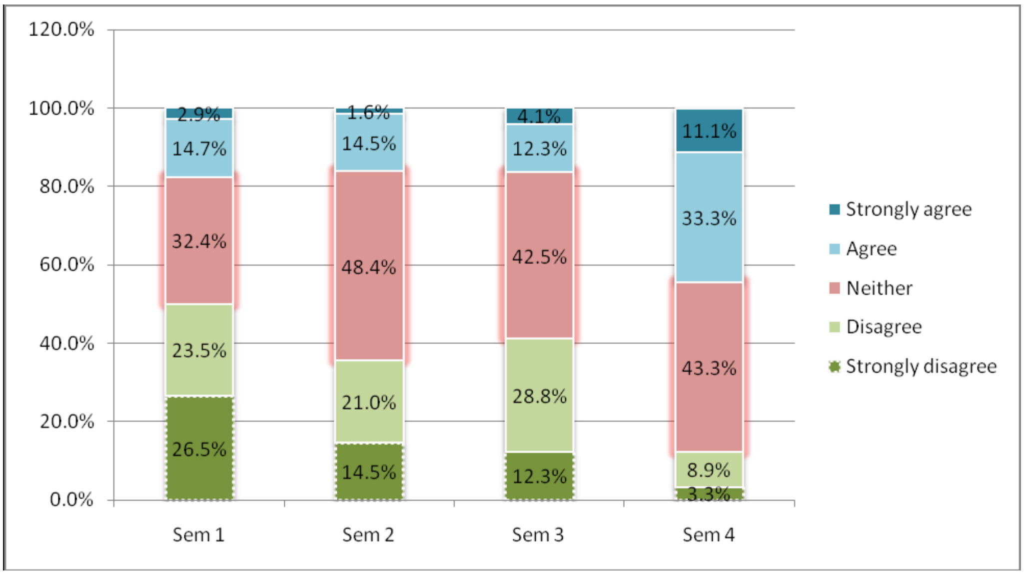

Figure 4: Helping students to become more effective and independent learners

Psychological Perceptions of Using the Eportfolio

Students were asked to indicate how they felt about using the eportfolio so far and in answering this question,they were allowed to choose more than one of the responses. Student perceptions are presented in Figure 5 below. This question may not be well constructed in that while the negative emotions are well represented in the literature, there are only two positive emotion choices for students and four negative ones. However, the data shows a trend of increasing enthusiasm and positive perceptions (from 3% and 17% respectively in semester1 to 17% and 49% in semester 4 and decreases in negative emotions such as uncertainty (from 20% in semester 1 to 12% in semester 4) , confusion (from 20% in semester 1 to 7% in semester 4) and anxiety (from 14% in semester 1 to 12% in semester 4). The proportion of students who remain neutral has stayed at a similar level at 26% although increasing in semester two and three to 34% and 36% respectively. While it is pleasing to see a reduction in negative feelings about the eportfolio, at semester four, still a quarter of students are neutral about it. This may be so because in semester four, half of the students were first time users and had limited use of the eportfolio in their course.

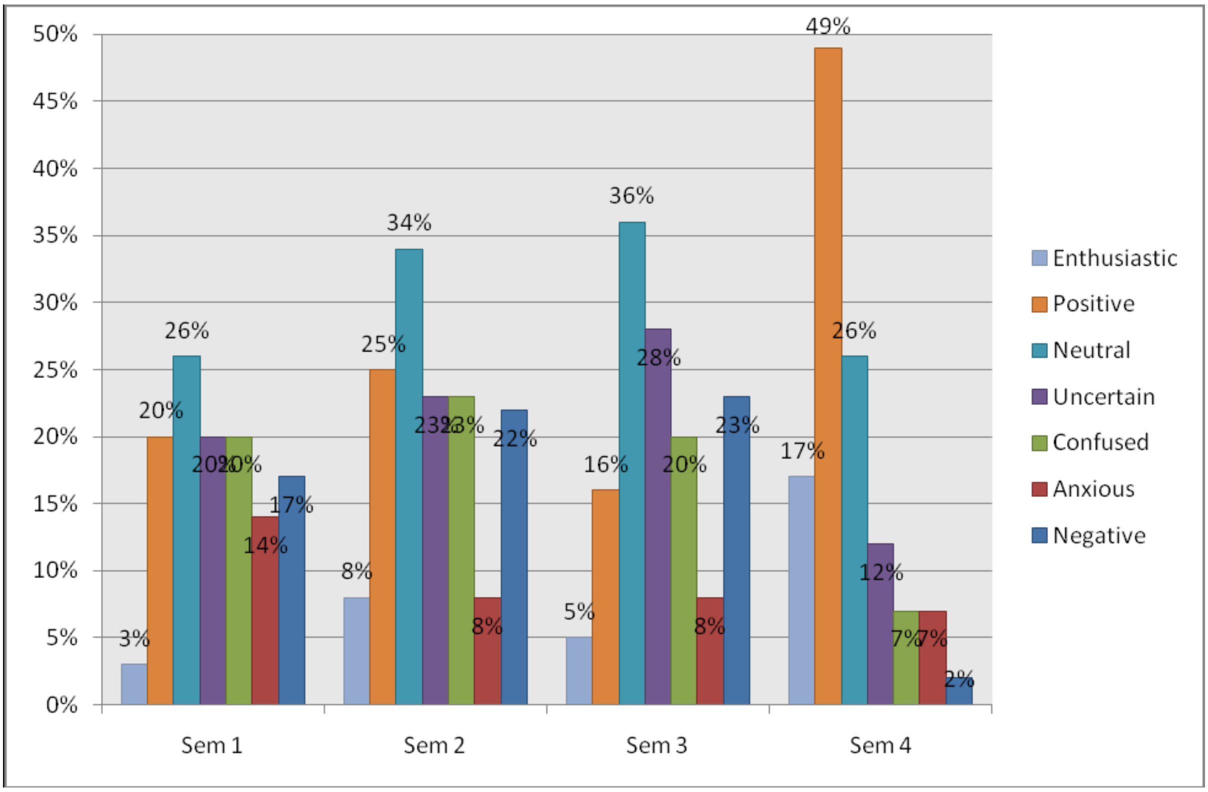

Figure 5: Psychological Perceptions of Using the Eportfolio

Challenges

Students were asked to identify in open text format the biggest challenge in using their eportfolio. Across the four semesters, 247 students (average of 92%) made 268 responses. Almost all of the comments were about developing their competence with the technology, for example, getting to know how to work with the Mahara ePortfolio - to navigate, to create and edit views and to allow specific views for lecturers and /peers:

> *It was hard to work out how to put things in and giving people views of your profile, and if you get a message, there needs to be a notice on the profile page (Semester 2 student)*

There were also emotional dimensions in that students described the familiarizing process as difficult, complicated, confusing, time consuming, not user friendly and involving many steps. The trend over four semesters showed that issues reduced in frequency. A student in semester 4 commented that**:**

> *[The biggest challenge was] the initial set-up, until becoming familiar with the process; just getting used to getting to know how to use it, but once I played around with it, I found it very useful.*

Discussion

The results indicate positive trends in the student body as a whole as the eportfolio technology and its accompanying pedagogy was developed within the programme. Results for the first three semesters are likely to be influenced by software issues and the residual impact on students. However by semester 4, these were addressed and the results are noteworthy because they indicate that as students have more exposure to eportfolios, in a context where teachers are increasingly knowledgeable about their learning benefits and responsive to student issues, that students do begin to appreciate the ways in which they might help them to learn. Alternatively the results indicate that students are adaptable and can get on with their learning in a changed technological and pedagogical environment. The overall results also have value because they represent the views of students across Years 1, 2 and 3 of a programme from 10 classes and include most of the students in each class.

The high levels of recognition of the value of the eportfolio for storage and organisation is well represented in the literature. Lopez-Fernandez and Rodriguez-Illera (2009) found that students considered that the main advantage was the pragmatic one of "a private VLE" (p.614). This illustrates the very basic role of the eportfolio as a digital repository (JISC, 2008). The literature indicates that there is a challenge in moving students beyond the digital dimensions of the technology and on to recognising its potential for supporting learning and learning processes. Our results provide some evidence of growing recognition of this over time by these students in the areas of evaluating and reflecting on the learning processes and keeping track of their progress and considering areas of weakness. This research confirms the findings of Bolliger and Shepherd (2010) and Lin (2008) who all identified similar benefits around these learning processes, although at slightly higher proportions for reflection (80% and 87% respectively). The results validate a major benefit of eportfolios in their support of reflection which is recognised as fundamental to the construction of knowledge and differentiates the role of the eportfolio as a mere repository of knowledge (Riedinger, 2006)

The role of the eportfolio in helping students to become more effective and independent learners was less established over four semesters. Chau and Cheng (2010) found that independent learning can be supported by eportfolios but they also identified obstacles to its development. In addition to the students' focus on the eportfolio as a product rather than a process, they also discussed the role and identity of teachers and the need to reconstruct the teaching relationship to be more student-centered. Lastly they noted the tension between universities' current focus on the eportfolio as a showcase for its graduates' attributes versus it use as a personal learning space for students. From our (New Zealand) perspective, there are broader issues associated with equity goals for universities. The elasticity of eportoflios means that it can support and encourage learning and self expression in a variety of media and across diverse experiences and therefore support a wider range of students. The tension between institutional and personal goals for eportfolios is complex and unexplored and mirrors broader national issues such as student mobility and the need for systems which can support transition and credit moving (Hallam et al, 2010) however in a manner which protects citizen's privacy.

Despite the challenges of learning to use the technology effectively, levels of enthusiasm and positive feelings increased steadily across the four semesters and feelings of uncertainty, confusion, anxiety and negativity decreased commensurately. The extent of change is not as great as that measured by Lopez-Fernandez and Rodriguez-Illera (2009) who reported that students were initially equally either calm and confident or confused and bored, but by the second month of use, 79% of students were positive. These results contrast with Tosh et al's (2005) study where many students had negative feelings about the eportfolio which were expressed through lack of buy-in and lack of motivation. These appeared to be associated with the time involved to learn to use the technology and the limited functionality of the platform which was frustrating for students. Our research tracks a developmental pathway which sits between these two studies.

More direct comparison might be made with the results of the survey of 101 Australian university students as part of the Australian ePortfolio Project (Hallam et al, 2008) because our questionnaire was adapted from this Australian one. However student participants were drawn from four different tertiary institutions and across many disciplines, so the context was quite different. Briefly, technical issues were not significant and students identified the greatest challenge as selecting experiences and the reflection process. In the area of learning, Australian students reported slightly higher levels of agreement regarding supporting evaluation and reflection on the learning process (84%) and similar levels of agreement concerning keeping track of progress and reflecting on weak areas (71%) and helping students to become a more effective and autonomous learner (less than half).

One of the themes in the research on student perceptions of eportfolios is that it takes some time for students to recognise the value of eportfolios to support their learning and development. Instead, students are either engrossed in learning to use the technology (Tosh et al,2005) or more interested in the pragmatic aspects of the eportfolio such as its ability to act as a repository and organiser (Lopez-Fernandez & Rodriguez-Illera, 2009) or to work as a showcase of their abilities for employment. This research provides some evidence of a trend of increasing recognition of the role of eportfolios in supporting reflection, and evaluation of learning, and, to a lesser extent, independent learning. The main challenge remains that of moving attention away from the technology and we are cognisant of student opinions that the eportfolio is not as easy to use as Facebook. We would like to see the eportfolio become part of the university learning landscape, and viewed in much the same way as its LMS. Our students have indicated that they would like to be able to access the eportfolio software after graduation for employment purposes and increasing availability might raise student perceptions of the learning and developmental value of the eportfolio.

Ramsden (2003) emphasizes the importance of contextual factors in influencing student perceptions of the learning context. The literature on eportfolios (e.g. Stefani,Mason & Pegler , 2007; Wetzel & Strudler, 2005) provides a significant body of pedagogical advice, however, there may be other factors which are influencing student perceptions. In the context of blended learning, Orton- Johnson (2009) found that students who did not engage with online materials acted in this way because they had concerns about the academic authenticity and trustworthiness of online materials. They wanted to remain with reading lists and books because they were reliable, safe and academically familiar. The challenge for students was to “reconfigure existing understandings and expectations of academic scholarship and reconstruct academic boundaries in new spaces" (p.837). Eportfolios, with their emphasis on digital media, representation, reflection, evidencing and synthesis also introduce new forms of academic scholarship which require students to construct new learning practices and change is not always easy, as this research indicates, and there are issues of sustainability.

Our results from this study provide some evidence of positive changes over time in students' perceptions of eportfolios. The results need to be considered in the light of particular contextual factors – the participants were student teachers who were already familiar with some dimensions of the eportfolio, particularly reflection. Students also came from classes of fewer than 50 students and this small class size is likely to have created a more responsive and interactive learning environment with ongoing professional feedback from teachers. The results also reflect the wording of the questions, which may not always have been clear to our participants. While this survey has provided an overview of student perceptions, there is little description or rationale for our student's perceptions and a qualitative study is being carried out to provide this complementary perspective.

Conclusion

The preliminary results from this three year project have demonstrated some trends of positive student engagement with eportfolios and the introduction of new learning spaces where students can focus on their development as reflective professionals. There may be a tension between this learner-centered focus and the broader use of eportfolios to evidence university accountability and graduate employability. In this case, strategies for reconciliation of the product and process aspects of eportfolios are highly desirable.

When students are learning to use a new technology and there are pedagogical changes associated with this, then challenges of the kind identified here may be unavoidable. Wetzel and Strudler (2005, p.26) argue that costs for students, such as time to learn to use eportfolios, can be substantial and this must be acknowledged by researchers and teachers who also must build understanding of what makes eportfolios meaningful and worthwhile for students. More longitudinal studies are needed to provide further insights into student perceptions of learning with eportolios.

The role of asynchronous discussion forums in the development of collaborative critical thinking

Nazanin Ghodrati
The University of Melbourne

Paul Gruba
The University of Melbourne

Blended learning approaches often make use of asynchronous discussion forums (ADFs) to enhance face-to-face learning, collaboration and co-construction. One aspect of research for such online tools focuses on the development of critical thinking. But what, specifically, is the role of such technology in such efforts? Over a semester, we collected data through classroom observations, semi-structured interviews and online postings. In our cyclical thematic analyses, we identified *virtual presence*, *timing*, *display presentation*, and *skill development* as influential factors regarding the development of collaborative critical thinking. Students, nonetheless, were often very frustrated with the tool. Improvements to the actual use of the tool, combined with greater guidance, may yield stronger results.

Keywords: critical thinking, collaboration, asynchronous discussion forums, higher education

Introduction

Blended learning approaches, which combine online technologies with face-to-face learning, are now an integral part of higher education (Amhag & Jakobsson, 2009; Edwards, Watson, Nash, & Farrell, 2007; L. Lee, 2009; Sharma, 2010). Because online tools used in higher education are predominantly text-based, several researchers have focused their attention to the role of asynchronous discussion forums (ADFs) within blended learning (Suthers, Vatrapu, Medina, Joseph, & Dwyer, 2008). Increasingly, investigators consider the possible affordances that ADFs may offer in enhancing learning, collaboration and co-construction of knowledge (Haavind, 2006; Land, Choi, & Ge, 2007). ADFs are seen to provide students time for thoughtful reflection, analysis and negotiation in evolving discussions (Yang, Newby, & Bill, 2005); if designed appropriately, the fora can facilitate truly collaborative activities (Janssen, Erkens, Kirschner, & Kanselaar, 2009).

Because a major aim of higher education is to develop critical thinking, it is important to investigate the role of ADFs in the development of critical thinking within blended approaches. For Kern (2006), such a search for "transversal relationships" (p. 202) investigates the transferability of learning from one communicative context or modality to others. Rovai (2007) highlights that participating in ADFs is a kind of collaborative activity which can give rise to critical thinking. ADFs can help learners engage in continual and extended reflection by allowing them to return to the online postings any time (Lea, 2001). In turn, sustained reflection can lead to a kind of thinking necessary to make connection between old and new information, and to synthesize these. Such reflection is proposed to result in the formation of new knowledge (Kol & Schcolnik, 2008).

Over 100 years ago, Dewey (1916) suggested that successful learning is dependent on the development of communities that engage in meaningful and critical communication. Smith (1994) stated that when a group collaborates effectively, its stages of cognitive development (e.g. exploring dissonance among ideas, synthesizing opinions, testing proposed syntheses) can be recognized as demonstrations of higher level thinking. Clearly, learning develops in the light of social interactions: within a community, individuals are challenged to demonstrate their ability to question, analyze, synthesize, evaluate, and make decisions (Deloach & Greenlaw, 2005). In turn, other community members respond by suggesting justified and supported insights and criticisms that lead to solving problems and generating new ideas. We recognize that collaboration in and of itself, however, does not necessarily lead to improved critical thinking as it is necessary to have a type of social interaction that moves beyond information exchange to one which encourages a more reflective and in-depth analysis (Abrams, 2005). Further, we understand that the potentiality of online learning tools to foster collaboration and co-construction of knowledge has been yet to come to fruition (Kreijns, Kirschner, & Jochems, 2003; Reeves, Herrington, & Oliver, 2004). As pointed out by Hovorka and Rees (2009) integration of well-crafted and engaging online tasks is time consuming, and access to multiple information and learning sources may decrease learners' participation. They add that ways of structuring threaded discussions (i.e. ADFs) and multiple blogs are valuable areas for future research. What we do not yet know, however, is what role the ADF itself plays in fostering interaction and learner development.

The aim of this paper is to examine the role of ADFs in the development of critical thinking. To achieve this aim, we report on the analysis of semi-structured interviews in a blended graduate subject at a large Australian research university. Following a brief review, we set out our approach to qualitative research. Next, we detail a cyclical analysis of the data in which four themes emerge. We define each theme, provide examples and then seek to expand current theoretical perspectives. We conclude the paper with an agenda for further research.

Research approach

One initial step in research is to set a *paradigm* that is defined by Kuhn (1970) as "the entire constellation of beliefs, values and techniques, and so on shared by the members of a community" (p. 175). The researchers' paradigm (i.e. their worldviews) affects the research design, data collection, data analysis, and interpretation. In this study, we adopted a qualitative interpretivist approach. At an ontological level, interpretivists view the world as a socio-cognitive construct where multiple realities shape a unified whole rather than assuming that social reality is external to the individual. Therefore, from an interpretivist point of view, the social world is best understood by taking into account the frame of reference of individuals in action within the social world. For us, we believe that individual thought processes, including critical thinking, cannot be investigated in a social vacuum. A range of multiple factors, both external and internal, influence the development of critical thinking within real life settings; clearly, our limited study cannot begin to capture each of them. We limit our investigation to demonstrated and observable critical thinking within an academic setting.

Site of the study

The site of this study was a once-a-week-2-hour face-to-face seminar called Technology and Language Learning

(TALL) supported by an online platform (the university's Learning Management System-LMS) where students used two asynchronous online tools: 1) ADFs (whole-class online discussions triggered by the subject coordinator), and 2) wikis (for students to discuss their final projects in small groups). We only looked at participants' experience of the ADF.

Participants

Participants in the study consisted of 12 graduate students and their subject coordinator within an intact subject at a large Australian university. Each agreed to participate in semi-structured interviews, and allowed analysis of their postings. Table 1 presents demographics of participants. For the sake of anonymity, pseudonyms were used.

Instruments

Over one academic semester, we collected data through classroom observations, conducted semi-structured interviews with the student participants and observed the ADF postings. Because of a limited word count for this paper, we focus on data from semi-structured interviews.

The semi-structured interviews were intended to provide an opportunity for participants to express ideas about their experience of the ADF, to identify factors affecting collaboration and critical thinking online, and to suggest ways of improving collaborative and critical engagement in the ADF. One-to-one interviews were conducted toward the end of the semester (week 9, 10 & 11). Interviews with blended students were conducted face-to-face and audio-recorded (except for one blended participant, Trung, who asked to be interviewed via online text-chat). Interviews with fully online students, on the other hand, were conducted online via text-chat or instant messaging. At the end of the semester, we interviewed the subject coordinator about student collaboration, critical thinking development and ways to improve the efficacy of the ADF.

After some transcription, the interviews were analyzed with the help of NVivo 9.0 through several cycles until a number of supported themes emerged (see Heigham & Croker, 2009; Miles & Huberman, 1994).

Table 1: Demographics of each participant in the intact class

	Name	Gender	L1	Mode of study	Level of study	Experience with ADFs
1	Sinta	Female	Indonesian	Blended	PhD	None
2	Trung	Male	Vietnamese	Blended	MA	High
3	Kalid	Male	Arabic	Blended	MA	Medium
4	Fahimah	Female	Arabic	Blended	MA	None
5	Maznan	Male	Malay	Blended	MA	Low
6	Grace	Female	English	Online	MA	None

7	Hung	Female	Vietnamese	Blended	MA	Low
8	Danny	Male	English	Online	MA	High
9	Carl	Male	English	Blended	MA	Low
10	Nancy	Female	English	Online	MA	N/A
11	Azin	Female	Farsi	Blended	PhD	None
12	Kamran	Male	Farsi	Blended	PhD	None
13	Alex	Male	English	Blended	Coordinator	High

Factors and indicators

As a focal point in our interviews, we asked participants what factors had affected their interaction and the development of critical thinking in the ADF. Taking into account both student and subject coordinator perspectives, four broad factors related to technology, English as a Second Language (ESL), task and curriculum were identified. Table 2 provides a summary of the factors and indicators that we found affected interaction and the development of critical thinking in the online discussions.

Table 2: Factors affecting collaboration and critical thinking in ADFs

Themes	Indicators
Technology	Display presentation Virtual presence Timing
ESL	Cultural background Cross-cultural communication patterns Previous educational experience (practice vs. lack of practice of critical thinking)
Task	Online discussion questions (uncontroversial topics/ close-ended vs. open-ended) Teacher-presence (teacher feedback absent vs. teacher feedback present) Online discussion rubric (general & implicit vs. specific & explicit guidelines) Assessment criteria (general & implicit vs. specific & explicit criteria) Focus on critical thinking and collaboration in offline and online classroom (implicit vs. explicit)
Curriculum	Focus on individualistic/ competitive learning vs. collaborative learning at the departmental level Focus on vs. lack of focus on collaborative critical thinking at the departmental level

In most studies of critical thinking in online asynchronous/synchronous discussions, participants did not demonstrate collaboration (Heckman & Annabi, 2003; Leng, Dolmans, Jobsis, Muijtjens, & Vleuten, 2009; Marttunen & Laurinen, 2009; McLoughlin & Mynard, 2009; Vaughan & Garrison, 2005). These researchers, and others, have found that the possible reasons that stifle collaboration include 1) the short time allocated to online discussions; 2) unstructured instruction or guidance (lack of sufficient teaching presence); 3) a lack of motivation or goals in online discussions; 4) the type of online tasks and triggering questions posed; and 5) the learners' educational experiences and cultural backgrounds. Perhaps not surprisingly, the results of our analysis of factors confirmed a number of these findings: Participants stated items 2, 4, and 5 as among the factors inhibiting their collaborative critical thinking online. Interestingly, however, none of the participants mentioned items 1 or 3 were inhibitors.

Affordances and hindrances of ADFs

As we continued our analysis, we focused specifically on the technology-related factors to better understand the role that the tools themselves may play in learner development of critical thinking. Four themes emerged: *virtual* *presence*, *timing*, *display presentation*, and *skill development*, and we expand on them below:

Virtual presence

Virtual (online) presence in ADFs in addition to the face to face presence in the classroom can serve as an affordance and/ or hindrance for interaction and/ or critical thinking.

Affordances

In interviews, participants were asked whether they enjoyed participating in the ADF. In response, many students noted that the ADF gave them an extra opportunity to share ideas with other students:

> There are many times when you might not think of something that you felt to be important while you're right there in the class but later on you have another idea and it's easy enough to just go to the discussion board at any time and let everybody else know what u think. (Carl)

> There were couple of points I could not mention in the classroom because of the shortage of time but in online discussions I could raise them and it could have bit of a discussion with our classmates. (Kamran)

Furthermore, some students mentioned that the ADF was a point of contact because, in the classroom, they would not normally talk to each other:

> I think it was important for me to almost like getting to know the other people in the class a bit better because you tend not to talk all that much with the other students in class and [the ADF] is something that lets you to certain extent get an insight into other people's ideas, other people's personalities in a way that you might not in a classroom setting. (Carl)

One reason why students thought that the ADF helped them in knowing other students better is that the TALL subject face-to-face sessions were in the form of lectures; therefore, students have little opportunity to engage in peer/ group activities.

Interestingly, many students preferred participation in the ADF as a way of avoiding face-to-face interaction:

> If you're facing this person, especially if you know that that person is more knowledgeable than you, then sometimes you feel reluctant; that it is not free for you to really open up yourself to give your own opinions towards the people, but as in the discussion board there, you don't necessarily meet with the people, right? So you can freely post your opinions there without the face threatening act. (Sinta)

Based on their responses, students' inclination for online rather than face-to-face interaction can be attributed to their personality. Anxiety, discomfort, and shyness were among reasons for preferring online interaction. These results confirm those of previous studies such as McBrien, Jones, and Cheng (2009) and Rovai (2007) which found learners' increased comfort level with Internet-based communication since anxiety of face-to-face interaction and criticism are eliminated online.

In addition, some students appreciated the fact that the ADF could be accessed and viewed only by other classmates and the subject coordinator (semi-public nature of the ADF). It was not an open forum where anyone browsing the Internet could enter and view their postings:

> I know that I personally would probably have big misgivings about putting my opinions up if [the ADF] was a completely open forum and everybody on the Internet could read it but as long as it stays within the subject I'm much more comfortable. (Carl)

Hindrances

Although most students appreciated the *virtualness* of interactions, some students mentioned lack of face-to-face contact with other students as one of the aspects of the ADF they did not like about the online discussions:

> Although [the ADF] is a wonderful tool in allowing us to feel part of the class, in reality we are not. Students don't know me, and I don't know them. I am a very chatty person:D and would readily take part in a classroom chat, because I am there to negotiate or clarify any misunderstandings. (Nancy)

Again, it would appear that personal preferences are at work. While many students preferred online interaction due to anxiety, discomfort and shyness, some preferred face-to-face interaction due to the more immediate social nature of physical co-presence. This issue is not problematic in blended learning contexts where the availability of both offline and online modality responds to different personalities and communication preferences. Unfortunately, Nancy who was a fully online student did not have the option offline (i.e. face-to-face). At another point during the interview, Nancy said that sometimes the written modality of the online discussions caused misunderstandings:

> I suppose there is also the notion of not knowing how your response is going to come across through a written post, for just as with email when the communication is not f2f [face-to-face] it leaves a lot open for interpretation. For example I had someone respond to one of my posts & I felt they were being a little negative, but I am sure in reality they were not. (Nancy)

Furthermore, the idea of posting ideas online where everyone in the class could see them made some students such as Grace, hesitant to post:

> The hesitation to post is because of the thought of] how to phrase it and then posting it for all to see, then it is open for criticism! You know the worry of 'what if I'm wrong!'. (Grace)

Although the affordances and hindrances of ADFs regarding virtual presence are not explicitly expressed by the participants to affect their collaboration and critical thinking online, they are still important to be considered. One of the main factors to take into account when evaluating applicability and suitability of an online learning tool such as asynchronous CMC (computer-mediated communication) is its potentiality to provide a platform for generating a sense of community or social presence among online members (McBrien, et al., 2009; Rovai, 2007).

Timing

The time spent on reflecting on and structuring posting on ADFs may serve as an affordance and/ or hindrance for interaction and/ or critical thinking.

Affordances

In line with the results of most studies (e.g. Kol & Schcolnik, 2008; McBrien, et al., 2009), students in our study enjoyed the flexibility of time and space which was afforded to them by the ADF:

> I think the best thing is that you can have discussion with a group whenever you want. You don't have to set a meeting time and everybody be present at that time, like I might post something on, I don't know, Wednesday and somebody might join me the day after that and that's really good. I like that best. (Azin)

Most students said that they preferred the written mode of the ADF to the oral mode of the face-to-face classroom. When we asked the reason, many students said that the ADF would afford them more time to structure their posts and to reflect on them:

> When writing I am having more time, more control on the grammar and on structures and the way I'm expressing my ideas and opinions rather than speaking. (Fahimah.

> Writing' rather than 'speaking' in online discussions affects my critical thinking process and answers; I have time to draft, think, rethink, edit, read aloud, read other people's posts and make sure I'm on the right track, explore other viewpoints I hadn't considered before adding my own post, perhaps even

change my line of thinking after considering other posts. The online mode particularly for the subject where I'm not so 'up with technology' is effective in that it allows room for the nurturing of critical thinking at the learner's own pace. If I were attending the subject in class I'm not sure I would be pushed to develop the same set of skills. (Nancy)

Hindrances

Since most students worked either part-time or full-time while studying or had workloads for other subjects, they admitted that they could not dedicate enough time to read and respond to others' posts and/ or to reflect more on their own postings:

> I'm working and also studying part-time so then it's quite difficult to find times to involve actively in the discussion board. That's the main problem actually, because at the end of the day after working hours we're very tired. Yes, I think that's the main problem. (Maznan)

> I want to give more time for the online post but I know that I have other assignments, other readings to do that makes me restrict myself to certain amount of time and just do it individually rather than collaboratively. (Fahimah)

Danny, a fully online student, was quite frustrated with the ADF due to lack of student-to-student interaction. Among the reasons he gave for why he thought there was no interaction among students (e.g. narrow questions, assessment criteria for the online postings, and lack of time due to working full-time), he mentioned that the delay in responses limited interaction among students:

> Given that we're placed all over the world, the delay in response times doesn't help [with student to student interaction. (Danny)

When there is little interaction and discussion among students, it is predictable not to find instances of co-construction of knowledge and collaborative critical thinking among students. This was in fact the case; through the content analysis of online postings we found few indicators of critical thinking in a collaborative/ dialogic fashion.[17]

Another factor expressed by one of the participants as a hindrance to online interaction was the time and effort needed to write her comments online. She felt that presenting her comments in the face-to-face classroom would be more spontaneous and interactive:

> In the ADF] you need to be more concise I think. You need to have your ideas sorted before writing. In class, you can start saying something, have a pause, someone else can add something. You can work on ideas together or at least start thinking about new ideas together. (Grace)

> [The hesitation to post is because] of the time needed to think about my view, how to phrase it. (Grace)

As evident in students' responses, time plays an important role in the quality (e.g. structure and content of postings) and the quantity of online interactions (e.g. number of postings and responses to others). Most students appreciated time affordances of the ADF. However, for some students delay in responses, the time spent on the online postings and on writing their comments became problems for collaboration and hence collaborative critical thinking.

[17] Due to space limitations, in this paper we do not report on the results of the analysis of online postings. The authors are planning to write a paper focusing on the indicators of collaborative critical thinking in ADFs.

Display presentation

Thread layout and appearance of ADFs may serve as demotivators for online discussion and interaction.

Hindrances

When we asked the students what they thought were some of the ways that the ADF could be improved, some students said that they would have been more comfortable if they had remained anonymous online:

> If there's nickname [in the ADF], we can see nickname or, for example the other students did not know that it is my response, just for example I can write Melbourne not my name Kalid. Just Melbourne or Sydney or just any nickname, I would felt more relaxed. (Kalid)

Another student found the presence of multiple threads decreasing the chance of interaction among students:

> [ADFs are] sometimes individualistic and sometimes looks like very collaborative once we get more people get involved with the one thread rather than making a new thread. (Maznan)

As it is clear in this excerpt, Maznan felt that much discussion occurred when comments were in one thread than in multiple threads. This was in fact the case; In week 9, when Alex, the subject coordinator, asked the students to stick to one thread and to respond to others' comments, students not only posted more (the average weekly postings increased from 18.33 to 26.66) but also responded more to each other's comments.

When participants were asked what factors affected their postings on the ADF, some of them such as Hung, mentioned the unengaging design of the online discussions:

> I guess that the discussion board is not very inspiring; I mean the layout or the design. It's not really friendly. (Hung)

This is an important issue to consider. Students use myriads of online software for communication and networking that in order to keep them attracted to the online tools used in higher education, IT and course designers need to adapt and use latest software that resembles the online communication tools students use outside the classroom.

Skill development

ADFs have the potential to help learners develop skills of writing, comprehension, and critical thinking.

Affordances

One of the interview questions was: What were some of the functions of the ADF for you? In response, many students mentioned that posting on the online discussion board 1) made them understand the weekly topics of the face-to-face classroom better, 2) helped them improve their writing, and 3) led them to develop their critical thinking:

1. Better understanding of topics

> I find that [the ADF] helps me get my head around some of the concepts discussed in the readings especially when everyone has experience teaching and different experiences using technology. I think it also makes me take more notice of the reading rather than just reading them because we have to. (Grace)

2. ADF improves writing

> Each time I post I learn something, and not to mention the language, I practice the language when writing the post [...] in the beginning I had to be careful and check everything before I post but then it turned out

to be interesting to monitor my language whenever I try to write so it makes me more careful to my writing. (Fahimah)

3. ADF Develops critical thinking

Before I post something into the discussion board I have a question of particular issue and then from there I'll read of course. I'll read the literature and then analyse it myself and then when you come to the discussion board there you have other's opinions and then you're gaining knowledge as well from them and you start to synthesize your own opinions from the literature from the question as well with the opinions from the other members of the discussion board. (Sinta)

The last excerpt shows that Sinta would employ critical thinking skills of questioning, analyzing and synthesizing, as outlined by Gunawardena, Lowe, and Anderson (1997), before, while and after posting on the ADF.

Students' responses in this regard confirm research by Kol & Schcolnik (2008); Haavind (2006); and Land, et al. (2007), where ADFs were expressed by students to afford them time for reflection, more attention and focused analysis of the learning content.

Hindrances

Lack of familiarity with the ADF, computer skills and slow typing negatively affected some participants' expression of thoughts and critical thinking in the ADF, such as for Hung:

> I'm not very good at technology skills and computer skills and stuff. I'm not really comfortable with opening a discussion board, typing in. Sometimes I just find it kind of stopping me from thinking when I'm typing so sometimes I even have to get back to writing [on paper]. Typing takes more time so maybe when you are thinking and you are typing, the speed of typing cannot catch up with what you are thinking. (Hung)

Participants' perspectives on affordances and hindrances of the ADF indicate that apart from factors such as educational and cultural background, online task designs, and how the curriculum is designed, technology can affect the extent of interaction, collaborative discussion, and critical thinking. Table 3 below summarizes the affordances and hindrances of ADFs as emerged from the interviews.

Table 3: Affordances & hindrances of ADFs

Themes	Affordances	Hindrances
Display presentation		Non-anonymity of ADF Large number of threads Unengaging ADF layout
Virtual Presence	Extra opportunity to share ideas Way to avoid f2f interaction Point of contact with other students Semi-publicness of ADF	Lack of physical contact for online students Misunderstandings due to written mode Publicness of ADF & concern for criticism
Skills	Better understanding of topics ADF improves writing ADF Develops critical thinking	Lack of familiarity with ADF Typing
Timing	Flexibility of time and space in ADF Time to structure your post Time for reflection	Delay in responses Time to dedicate to the ADF Time & effort for writing

Theory development

Computer-meditated online learning tools in general and ADFs in particular with their potentiality to provide a platform for co-construction of knowledge are proposed to support a number of theories such as Vygotsky's (1978) socio-cultural theory, social-constructivism, and Moore's (1993) theory of transactional distance (Anderson, 2008; McBrien, et al., 2009; Moore, 1993). According to socio-cultural theory and social constructivism, cognitive development takes place first on the social level and is then internalized on the individual level (Vygotsky, 1978). Extending this notion to learning, based on these theories, learning is a social activity and learners make meaning through dialogue. According to the theory of transactional distance, three main elements in online learning contexts are dialogue, structure, and learner autonomy (Moore, 1993). The main overlapping key concept among these theories is the concept of *dialogue*. Creating dialogue in the form of learner-instructor, learner-learner, and learner-content interaction is of utmost importance in online learning contexts such as ADFs (Anderson, 2008; McBrien, et al., 2009; Rovai, 2007). However, based on previous research, it appears that dialogue in the form of learner-learner interaction is less common online, and if learner-learner interaction is happening, it is less likely to be in the form of an interaction which moves beyond the exchange of information to a more reflective and in-depth discussion (Lee & Tsai, 2011; Leng, et al., 2009; Marttunen & Laurinen, 2009; McLoughlin & Mynard, 2009). Having examined the results, we also found that learner-learner interaction, in which students would engage in co-construction of knowledge and collaborative critical discussion, did not happen in the online discussions.

As mentioned before, many online learning researchers have celebrated the potentiality of online learning tools for creating an interactive and collaborative learning context. However, according to the responses of participants in our study, we found that there are a number of factors such as those related to technology, ESL, task, and curriculum which compete with notions of social nature of learning. In our study, we highlighted the role of technology-related factors, among others. We realized that ADFs can work both as an affordance and hindrance for collaboration and critical thinking. In this regard, for instance, Reeves, et al. (2004) highlighted the deficiency in commercial course management systems that are commonly used in higher education. Alongside other scholars, such as So and Bonk (2010) and Vonderwell (2003), they found that such systems tend to be used as replication of traditional face-to-face classrooms. They suggested that instructional designers in higher education need to see collaborative online learning tools as *a complement* to the traditional classroom rather than as a replacement to it.

Lee and Tsai (2011) have highlighted that collaboration takes place through a variety of influences. That is, for each learning context which involves collaboration, there arises a local perception and application of collaborative task or what it means to be collaborative; accordingly, different contexts give rise to different collaborative activity. In the same vein, Anderson (2008) has highlighted the drawback of prescriptive theories of online learning which try to prescribe how interaction and learning should take place. Alongside Anderson, we believe that the most appropriate theory of online learning is a descriptive one; a theory which embraces particularities and limitations of an online learning context and accommodates for them accordingly.

Conclusion

In line with other studies, we found that text-based online learning tools provide a number of affordances when integrated into the face-to-face classroom. Some of the affordances are opportunities to express and share ideas, time for reflection, better understanding of in-class topics, and developing critical thinking. Nonetheless, further research must present a more realistic account of the hindrances of ADFs, some of which were expressed by the participants in this study; such as the fact that ADF required a lot of time which students could not dedicate, did not permit anonymous postings, and that there was a delay in responses. While further research is needed to investigate the roles played by factors related to ESL, task, and curriculum in developing collaboration and critical thinking in online discussions, this paper suggests that technology be further problematized; that is, rather than a silent assistant, ADFs in and of themselves require greater attention in their role in shaping online discourse.

Achieving meaningful online learning through effective formative assessment

Joyce Gikandi
University Of Canterbury

An online course was studied to investigate how integration of formative assessment enhanced the course design to facilitate learner engagement with meaningful learning experiences within the context of ICT–related professional development for teachers. The study employed case study methodology. Participants included postgraduate students enrolled in an ICT-related online course and the course teacher within a New Zealand university. Based on the findings, integrating ongoing authentic assessment activities within teaching and learning processes engaged the students actively, and provided opportunities for ongoing monitoring and assessment. These in turn, elicited appropriate formative feedback to support and scaffold learning. These formative processes also fostered development of an effective online learning community. The interplay between formative processes and an interactive learning community sustainably fostered learners' engagement with critical learning experiences including active, interactive, contextual, collaborative, reflective, multidimensional perspectives, and self-regulated aspects of meaningful learning, which ultimately supported development of robust and transferable knowledge.

Keywords: Online learning, formative assessment, effective pedagogical strategy, meaningful engagement

Introduction

The concept of formative assessment is underpinned by three defining processes: "establishing where the learners are in their learning [in relation to the expected learning outcomes]; establishing where they are going; and establishing what needs to be done to get them there" (Black & Wiliam, 2009, p. 7). Convergence of formative assessment with the affordances of web-based technologies leads to the concept of online formative assessment. Effective integration of online formative assessment has the potential to facilitate and sustain meaningful interactions among learners and the teacher, and in turn foster development of effective learning communities to support meaningful learning and its assessment (Sorensen & Takle, 2005). Moreover, this can provide a systematic structure for effective support and learning scaffold through ongoing monitoring of learning and provision of adequate formative feedback. Ongoing learner support has been identified as a critical requirement for effective online learning, and can be essentially facilitated through sustained interactive collaboration among the teacher, peers and the individual learner (Ludwig-Hardman & Dunclap, 2003). In effect, this supports learners to engage productively, and stimulates self-regulation, which in turn supports learners to assume primary responsibility for their learning, an important requirement for success in online learning.

However, a recent review of literature in this field barely revealed any study that has holistically exemplified integration of online formative assessment, especially from the perspectives of supporting meaningful learning within the context of ICT-related professional development for teachers. This study aimed to fill that gap with a focus on how formative assessment supported online learners in developing transferable learning in an ICT in education course for teachers (among other educational professionals). The study also aimed to elucidate the critical factors that influenced its successful implementation.

Methodology

The study employed case study method to facilitate an in-depth investigation into the design and implementation of online formative assessment to establish its effectiveness in relation to enhancing learners' engagement. The study context was the online learning setting of a New Zealand University within a postgraduate program in education. The participants included the students enrolled in an ICT in education online course and the teacher who was also the course designer. The study was framed within authentic learning theoretical perspectives (Barab, Squire, & Dueber, 2000). The data collection techniques included online observations, analysis of the archived course discourse, and semi-structured interviews. The data from multiple sources was analyzed using inductive and deductive analytical techniques, which were subsequently triangulated to corroborate the evidence.

The study findings and their implications

Online formative assessment was exemplified through various elements in this online course. These included a variety of ongoing and authentic assessment activities, adequately defined learning goals and expected outcomes, and opportunities for ongoing monitoring, assessment and formative feedback. These enhanced learners' engagement with critical learning processes including active, interactive, contextual, collaborative, reflective, multiple perspectives, and self regulated aspects of learning. These aspects are critical to supporting meaningful learning as identified in a recent review of literature by Gikandi, Morrow and Davis (2011).

The current findings showed that integrating open-ended and flexible assessment activities that were relevant to real-world applications created a contextualized learning environment that facilitated learner autonomy and active cognitive engagement. This engaged students in meaningful ways, which confirms the findings by Gikandi et al. (2011). The teacher role as an expert facilitator was evident in the course through fostering shared purpose and understanding, scaffolding learning, detecting misconceptions and providing formative feedback. However, one particular student who was a unique case experienced extreme challenges within this authentic learning environment. This was particularly due to his learning style that did not fit well in online settings and was not flexible enough to adapt it fittingly despite the teacher's support and encouragement, and he voluntarily withdraw from the course towards the end. This confirms the findings of Gikandi et al. (2011) that identified learner's commitment as an important ingredient in achieving effective formative assessment in online learning.

The course design revealed a collaborative learning pedagogical approach that was facilitated through asynchronous threaded discussions. This fostered dynamic interactivity, co-construction of knowledge through multiple viewpoints, peer formative feedback, and promoted shared understanding of expected outcomes as the indidividaul students engaged with the assessment activities. This is consistent with findings of Vonderwell et al. (2007), and Sorensen and Takle (2005) that online formative assessment can foster opportunities for collaborative learning and assessment. Through these formative processes within the asynchronous discussion forums, the students were also able to share their ongoing work and/or ideas with peers and recieve critical feedback that supported them to improve their work and close their performance gaps.

Another key finding is how opportunities for ongoing monitoring and assessment were enhanced through ongoing documentation (archiving) and sharing (by being public to all participants) of learning and assessment processes and products. This also served an important purpose in informing formative feedback processes and serving as exemplars. The ongoing sharing of processes and products including publicity of learning needs and the received feedback also enhanced effectiveness and efficiency of feedback because the students benefited from their peers' feedback both cognitively and affectively. Effective formative feedback was critical to the effectiveness of formative assessment in this asynchronous setting particularly in relation to its immediacy, adequacy and interactivity. Feedback was timely and characterized by clues and probes as opposed to direct solutions. As a result, feedback was not an end in itself but an iterative and dialogic process that promoted reflective thinking and self regulatory strategies among the students, which in turn fostered deep inquiry. More importantly, the adequacy and interactivity of feedback was enhanced by the uniqueness of the online setting (as compared to face-to-face settings) in relation to offering the participants opportunities for revisiting previous postings (contributions by self and/or others within the online discourse). This greatly enriched formative feedback processes in two important ways: firstly, it facilitated internal feedback (self reflection or interaction with self) as the students had sufficient opportunities to review the feedback they received (the responses from others) and revisit other related previous postings. Secondly, the students had ample time to review and rethink upon previous contributions before they composed their responses as feedback to peers.

The findings also reveal that effective integration of online formative assessment promoted students' engagement in self-monitoring and assessment, reflectivity and self-regulatory processes. The students progressively developed mutual responsibility and recognized themselves as source of learning support for their peers. This lead to development of a supportive learning community within this online course which reciprocally nurtured the formative processes. Through these aspects, it is evident that the teacher and students' roles were reconstructed because teacher and students alike assumed new roles as facilitators and co-participants. Notably, the role that the teacher played in fostering shared understanding of purpose and responsibility cannot be underestimated; in effect, it required the teacher to be vigilant and open-minded in order to effectively facilitate the online discourse and ensure the efficacy of the shared role within formative processes and responsively manage the emerging issues.

To this end, it is clearly evident that framing online formative assessment within authentic learning perspectives offered an effective learning environment by creating an authentic environment that fostered learner engagement with meaningful learning experiences. This implies that online educators can exploit the potential of online formative assessment to develop learner and assessment-centered environments that focus on enhancing learning experiences as opposed to teacher-centered environments where the teacher is the expert and learners assume a passive role. Online formative assessment can offer a means to create effective environments where learners are actively engaged with valuable experiences and take primary responsibility for their learning, which is critical for successful online learning. These experiences inevitably supported development of robust knowledge, and enhanced learners' ability to effectively transfer ICT knowledge and skills in their own professional practice.

A community approach to the development of widgets to support personalised learning for disabled students.

Voula Gkatzidou & Elaine Pearson
Accessibility Research Centre
University of Teesside, UK

The rapid pace of change of the knowledge intensive era, supported by the emergence of Web2.0 and the consequential growth of personalised applications, has fuelled debate on the notion of Personal Learning Environments (PLEs). The concept of personalisation, adaptability and accessibility is particularly pertinent in terms of creating a learning environment that meets the individual needs of disabled learners that cannot be met by standard approaches and could affect the student's ability to access learning at all. This has led us to explore the potential of the personalised development of learning applications to provide the choice of tools, applications or services to support the learning experience of disabled students. This paper examines a community approach to the design, development and evaluation of open source widgets, through a project funded as part of the JISC Distributed Learning Environments initiative: Widgets for Inclusive Distributed Environments (WIDE).

Keywords: accessibility, widgets, community of practice, personal learning environments

Introduction

Developments in Web 2.0 and cloud computing bring new opportunities for selecting and using tools to support communication, self organisation, independence and self regulation. The global learning landscape of the twenty-first century is being transformed and shaped by the uptake of digital communication tools and ubiquitous networked applications, along with the changing characteristics, needs and demands of students (McLoughlin & Lee, 2009). This transformation is supported by the convergence of three trends: the growing number of Internet-capable mobile devices, increasing flexible web content and continued development of the networks that support connectivity (EDUCAUSE Horizon Report, 2011). At the same time, the rigidity of established learning management systems (LMS) is being challenged by the potential to connect and mash up different web based applications and the considerable growth in the widgets/mobile applications market. The concept of a mash up Personal Learning Environment that allows the learner to select and configure their own set of applications is receiving considerable attention. This is particularly pertinent in terms of meeting the needs of disabled learners who may have very individual needs that may render standard interfaces and environments inaccessible and affect the students' ability to access learning.

A recent survey on the e-learning experiences of disabled students in HE (Seale et al., 2010) has highlighted an 'all or nothing' approach to assistive tools, in which you either have the technology or not. Students who use proprietary access technology have little or no way to adapt it or select individual components to suit their own needs. Free or open source software offers the opportunity for disabled users to take control of their own computing, to select software fit their needs rather than passively accepting whatever developers choose to offer them. Focusing on enhancing the e-learning experience of disabled learners, this study explores the design and development of small discrete applications and tools that support the, sometimes, very specific requirements of learners, in an attempt to move closer to the goal of inclusive, accessible and personalised learning.

Widgets for Inclusive Distributed Environments (WIDE), a project funded as part of the UK JISC Distributed Learning Environments initiative, explored the potential of widgets as a component of a mash up personalised learning. It begins by discussing the potential of widgets in enhancing the learning experience of disabled students by offering support in terms of personalised assistive technology tools and learning aids. The paper continues with an overview of participatory approaches in e-learning and then goes on to describe a mixed methodology for the design of widgets to support disabled learners that draws on principles from participatory design and agile development methodologies. Each phase of the study is presented and discussed in terms of the participants' involvement. The findings of a preliminary evaluation of the widgets developed as a result of the project is presented and the paper concludes with a discussion of further work required to support the wider creation and adoption of widgets to support disabled learners.

Background Research

Advances in technology supported by the emergence of Web2.0 and consequential growth of personalised applications, has fuelled debate on the notion of Personal Learning Environments (PLEs). This means that software applications need no longer be monolithic and can naturally be separated into distributed components (Raman, 2008). The application logic and the data resides in the network cloud, while the presentation and interaction can be presented to the user in a form suited to the user's needs. The concept of a Mash-up PLE is to provide an open set of learning tools for the users to gather as they see fit in order to build his own environment rather than offering a monolithic platform which can be personalisable or customisable by users (Wild et al., 2008). The third model of the JISC CETIS models of Distributed Learning Environments (DLE) (MacNeil, S. & Kraan, W. 2010) illustrates an example of how a mash-up of a variety of sources can provide personalisation through the use of different services gathered within a Virtual Learning Environment (VLE).

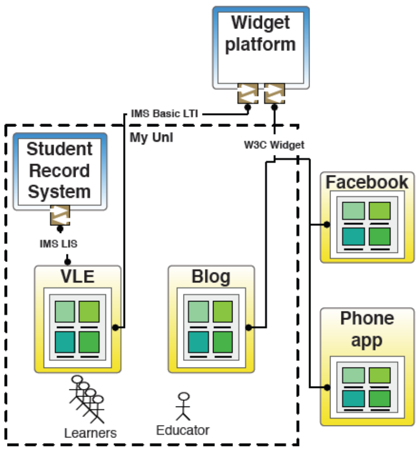

Figure 1. JISC CETIS model of distributed learning environments (Model 1)

The diagram (Figure 1) illustrates one possible instantiation where a single hosting service 'in the cloud' serves a collection of educationally useful, standardised widgets to a VLE, a blog, a social network and a smartphone app. A collection of services is gathered in one place and from there broadcast to a range of platforms.In terms of this project, we have identified the need for an additional platform that, in a Community of Practice development approach, might exist parallel to the Widget Platform. Widgets –especially those created to meet the specific needs of disabled students who may require particular adaptations – are dynamic and not necessarily static in content or structure.

This concept of distributed learning environments, led to new ideas in the e-learning community to promote adaptability and personalisation of virtual learning environments especially for adaptation to specific needs and preferences. The experience of using a set of widgets in a learning environment supports the concept of mash-up PLEs in that it allows students to use applications or tools as they see fit. A mashup of different widgets can serve as front-end applications for distributed learning aids and services in a mash up based personal learning environment (Taraghi et al., 2009). The way widgets are conceived promotes the granularity of web applications, which in terms of e-learning means a more adaptable, flexible learning environment.

Widgets represent discrete tools, applications, assistive technology or other learning supports to perform specific functions. In the context of the research reported here, a widget is considered as a discrete, self-contained application that works across a range of browsers or platforms (Pearson et al., 2011). The widgets, applications and gadgets (WAGs)market has had considerable growth over the past several years, as we turn to mobile applications for immediate access to many resources and tasks that once were performed on desktop computers.. In education, though, the opportunities for choosing and using such software are limited. A quick search of the Opera widget site (http://widgets.opera.com/category/) and Google gadget site reveals no specific category for education or for accessibility. (http://www.google.com/ig/directory?synd=open). These emerging technologies provide an opportunity for the creation of small, bespoke widgets that perform specific functions and act as assistive technology and learning aids to support learners with disabilities. In terms of widgets to support disabled learners, examples include widgets that support learners with motor difficulties in completing web forms, widgets for creating high contrast view/themes or activating voice recognition for students with vision impairments, or symbols-based calendars for students with learning disabilities or cognitive disabilities that are non-text users.

Nevertheless we acknowledge the danger of systems designed specifically to support disabled learners is that they can be costly, and may be limited in their potential for sharing and re-use. Secondly the expertise and best practice of local practitioners producing specific solutions is difficult to identify and adopt by the wider community (Sampson & Zervas, 2010). For this reason, the aim of this research is to make widgets that meet specific needs, but at the same time could be easily adapted to suit other specific needs as WAGS are often proprietary and application specific. The intention is not to provide a wholesale solution, but rather to support the use and development of widgets individually, or in collections of other widgets and learning resources.

Widgets for Inclusive Distributed Environments (WIDE) Project

This research integrates participatory design and agile development approaches through a project funded as part of the JISC Distributed Learning Environments initiative: Widgets for Inclusive Distributed Environments (WIDE). WIDE is a joint project that comprises accessibility experts, academics, researchers, teachers, tutors and other practitioners from the Higher, Further and Specialist College education sectors. The project aims to develop resources that extend the functionality and flexibility of virtual learning environments to meet the needs of learners with disabilities who may require their learning resources to be adapted to meet their specific needs (MacNeil & Kraan, 2010) and contributes to the vision of an adaptable and personalised learning environment (Pearson & Gkatzidou, 2010). The study adopted a participatory approach in that it enabled researchers and technologists (WIDE team) to work together with disabled students and practitioners (in teaching or support roles), to identify a student need, and to explore the potential issues and impacts of potential solutions to that need. The ideas were then translated into a design document, which represents a learning design for a widget that will best support the student. The WIDE development team then adopted an agile development approach to produce iterative prototypes of the widgets in close cooperation with the designers to produce a bank of high quality widgets that can be plugged in to a range of learning environments, developed by and for those responsible for supporting disabled students in further and higher education and in specialist colleges.

THE WIDE Methodology

The WIDE project adopts a mixed methodology that draws on principles from participatory design and HCI under the umbrella of agile development. This methodology responds directly to the call for methods that empower learners to be the ones who highlight the issues which are important to them (Sharpe et al., 2005). Participatory design can be defined as an approach to design that attempts to actively involve all stakeholders in the design process to help ensure that the product designed meets their needs and is usable. In the context of the WIDE project and in order to avoid the dangers and pitfalls of a technology-driven pedagogy (Salaberry, 2001), the community of practice involves disabled students, researchers, technical experts, teachers and specialist teachers.

Stakeholders	**Interest/Stake**
Disabled students	Creators and end users with specific needs.
Teachers of students with disabilities	Users of widgets. Established needs for flexible solutions to student support learning.
Researchers	Understand issues of e-learning development to support personalisation and accessibility.
Tutors/Carers	Understand needs of disabled learners.
Practitioners from HE, FE, Specialist Colleges	Need to understand how widgets can be used to provide flexibility to VLE.

Table 1. Stakeholders Table

Nevertheless, it's the use of participatory design together with agile development methodology that distinguishes the project from other studies that have researched the experiences of disabled learners, in that participation is conceptualised as involving them more than as research informants. Agile development is not a single, well-defined process, but a common name for several processes and methods, sharing a set of core ideas, values and principles of software development (Blomkvist, 2006). The core values and principles as defined in the Agile Manifesto (Agile Alliance 200) place less emphasis on the process and its deliverables, and focus instead on the people involved and their co-operation in order to produce results more quickly with reduced risk of failure or delays. The driving force behind the agile perspective is to shift the overall focus of software development to a more agile or lightweight perspective (Cockburn 2002). For this reason, agile methods provide a lightweight approach to development where requirements and solutions evolve through collaboration and through iteration. The nature of widgets lends itself to agile iterative methods (Leeder, 2009) as a basic functional widget prototype is straightforward to develop and deploy to users in a series of design iterations. Nevertheless, from an HCI perspective, agile processes do not inherently provide the required support for user-centred design, but can function as one pillar on the way to an integrated approach (Memmel et al., 2007).

With regards to the participation of the community of practice in the WIDE study, there were three key phases of participation:

- Phase One: Opportunity to contribute own experiences of e-learning and identify potential tools to support their learning.
- Phase Two: Opportunity to conceptualise and design the widgets to meet the identified needs.
- Phase Three: Opportunity to evaluate their 'own' and other widgets developed.

In the first phase of the study and in preparation for the workshop, the teacher participants were invited to identify with their students what they think would be the most useful means of support in terms of widgets. In the case of tutors working in specialist colleges with students who are not always able to articulate their needs, then the tutors would contribute their own ideas from direct experience of supporting their students. In the second phase of the study, the Community of Practice (CoP) was involved in producing learning designs to encapsulate their ideas for widget. In the third phase of the study, different stakeholders evaluate different aspects of the study; users evaluate the widgets they have designed, disabled students who have not been involved in the workshops evaluate the widgets and external consultants evaluate the process of setting up and supporting the community of practice. Each of these phases will be described in detail in the following sections.

WIDE Pre-Workshop participation (Phase 1)

Teachers and students discuss the problems and difficulties the students experience in using the VLE, organising their work, carrying out assessments or completing assignments. They identify the kinds of tools that would help them to achieve these tasks or support their learning. These discussions would be encapsulated later on in the Phase 2 workshops in the form of personas and scenarios, so that, although students may not be directly involved in that phase, their requirements are captured.

WIDE Widget Design Workshops (Phase 2)

During the second phase of the project, through a series of workshops and follow up activities, the participants were given the opportunity to identify appropriate learning designs (digital and non-digital) derived from practice that can be re-purposed as widgets. The WIDE workshops were run on three separate occasions at three different locations, at Teesside University, at a specialist FE college in Mansfield, and at the JISC TechDis in York). The workshops involved a total of 11 teams of four to six people (49 participants in total), with an average of 15 participants at each workshop. During the workshops, participants were divided into groups of five, where each group would include a disabled student, an academic/teacher, a researcher, a tutor/carer, and practitioner where possible in order to obtain detailed and highly contextualised learner voices. Each group was assigned to a developer and was facilitated by a member of the WIDE team, whose role would involve bringing together the diverse expertise of the participants and overcoming the common challenges of participatory design in terms of gaps in communication (Segalowitz et al., 2010) and alignment of expertise with the community (Nwigma, 2009). Wenger (1998) indicates that leadership and facilitation roles are crucial to all CoP and that should be filled by "recognised experts [who] need to be involved in some way, even if they don't do much of the work", and that their presence is needed to legitimise the community "as a place for sharing and creating knowledge".

The outline of the workshops included:

- Overview of open source and freeware accessibility software
- Introduction to creation and use of mobile prompts
- Widget design brainstorming in small groups (including design facilitators)
- Working collaboratively on poster templates to create designs in small groups
- Presentation and discussion of designs
- Widget development and evaluation plans

At the workshops, participants were introduced to examples of learning supports, briefed and prepared for the activities. The brainstorming session elicited a number of ideas (typically six or seven from a group of four) from which the groups then select one or two to develop full designs.

During the design process each group developed their initial ideas further with the aid of a set of specially adapted templates learning design and storyboard templates. For these we used A0-sized laminated posters (Figure 2 and 3) in order for the participants to organise their expert knowledge to produce a learning design that encapsulates the necessary information on the interface and functionality of the widget. These posters templates were designed to be user-friendly, requiring no technical expertise and therefore suitable for our participants and suggestive rather than prescriptive. They include some simple prompts and principles, from which ideas can be developed and knowledge can be captured and expressed.

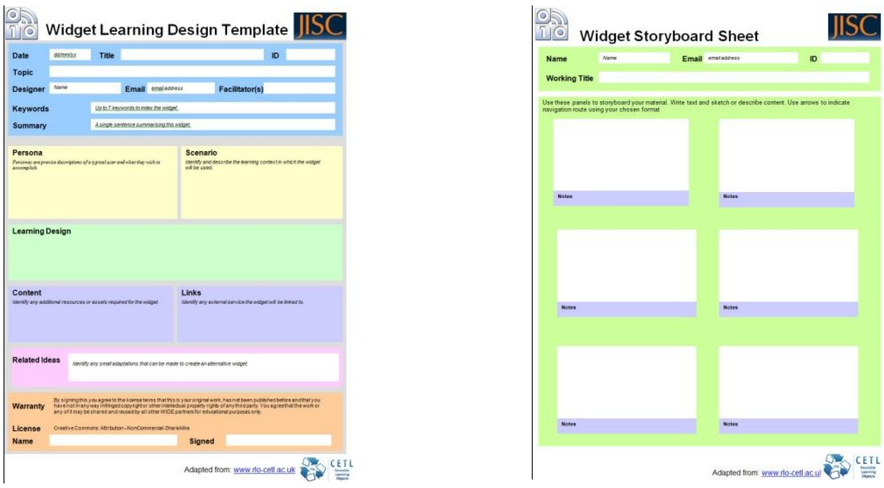

Figure 2 and 3. Widget Learning Design Template and Storyboard

The Widget Learning Design Template provides all the necessary information on the interface and functionality of the widget. It consists of a number of sections that the participants need to fill in to describe the widget in detail. Participants were required to complete the following sections on the template:

- *Persona*: a precise description of a typical user of the widget and identifies what the user needs to accomplish
- *Scenario:* identifies the learning context in which the widget would be used
- *Learning Design:* describes exactly what the widget will do and how it will operate
- *Content:* identifies any additional resources or assets that would be required for the widget For example a 'calendar widget will require the designer to provide a list of events
- *Links:* identifies any external service the widget might need to be linked to. For example a mobile widget using GPS
- *Related Ideas:* participants are encouraged to identify any small possible adaptations that can be made to create an alternative widget
- *Warranty:* a short statement signed by the designer to license the work under the Creative Commons License

The storyboard template allowed the participants to document and design the interface of the widget. In some cases, participants were required to provide information not only for the user interface of the widget but details on the design and functionality of the administrative side.

On completion, the learning designs were photographed, archived digitally, and made available on the WIDE wiki where the final widgets are available for download and distribution. This approach was adapted from the learning object design approach used by the Reusable Learning Objects-Centre of Excellence in Teaching Learning (Leeder, 2009). However many of the elements such as personas and scenarios are commonly used in user-centred design or user-experience design.

Widget Development

A total of 31 widget designs were produced during the WIDE workshops, which meant that each team produced more than one design. These designs include a wide range of widgets such as:

- Visual shopping list widget that provides symbol-based task list (Figure 4).
- Digital abacus, a learning aid widget to assist students with motor difficulties in their math calculations (Figure 5).
- Sentence jumbler widget that shuffles the words in a sentence requiring the user to put them in the right order.
- ‘I am here widget’, a widget that allows the user to report that they have arrived at a specific location.
- ‘Ruler’, is a simple widget that supports dyslexic students reading and tracking text.

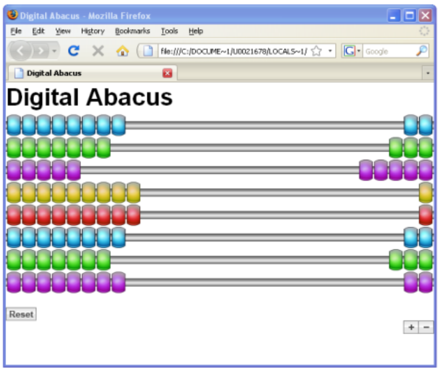

Figure 4. Visual Shopping List Widget **Figure 5. Digital Abacus Widget**

The widget designs were classified into three categories:

- Tools: self-contained widgets that might require access to a Web service but do not store or edit data.
- Applications: complex widgets that use Web services to store and retrieve persistent data.
- Learning Objects: independent self standing units of learning content.

The widgets were most commonly classified as tools (61%) with around a third (26%) being considered as applications and only a few were classified as learning objects (13%).The designs identified by the participants included a wide range of different types of widgets – all designed to meet particular needs - categorised as time management widgets (13%), task management widgets (16%), assistive technology widgets(16%), learning aids (16%), independence tools (19%), social network widgets (3%), content-free apps (3%) and learning objects (13.5%).

Following the design process, each of the widgets were classified in terms of a number of factors grouped into technical elements (such as whether they needed access to a database, web-services, operating system or GPS) display features (widget window, desktop, full-screen, movable, resizable, dockable etc) and application compatibility (such as to mobile device, browser or VLE). These features determined the development platform of the widget. As each widget was developed, a liaison from the WIDE development team contacted the designer to seek clarification or request additional content and invite feedback on the widget (design, interface, functionality etc). This ensured that the designer was aware that 'their' widget was being developed and that they were involved in the whole process.

The intention was to develop W3C standard, free, open source widgets that can run in any web browser, do not require installation and are platform independent. Apache Wookie (Incubating) is an application that provides a W3C-compliant widget server where you can deploy widgets and serve W3C widgets from the Wookie server in third party applications. Although the original intention was to develop Wookie (2010) widgets, in some instances this was not feasible, particularly if the widget required access to the desktop or local device.

As a result, three types of widgets were developed:

- Wookie widgets: standard W3C widget running from a Wookie web server.
- Opera widgets: standard W3C widget but benefitting from installation on a desktop or devices hosting the Opera web browser
- Mobile, desktop or windows app: designed primarily to install and run on a specific mobile phone or device, laptop or as a windows app and therefore usually not W3C-widget compliant

In practice, the majority of designs (23) were implemented as Wookie widgets, while some (8) required facilities that weren't available to the widgets standard APIs so needed to be Opera (6) only or Windows applications (2).

WIDE Evaluation (Phase 3)

In accordance with the principles of participatory design, the CoP was involved in every stage of the evaluation:

- Analysis and design stage: Accessibility experts and technical experts evaluate and advise on proposed designs.
- Implementation stage: Evaluation of prototype widgets by designers
- Deployment: Widgets evaluated in practice by designers (post project)
- External evaluation: an evaluation of the widgets developed, the design approach and the potential for adaptation is being carried out by accessibility experts external to the project.

A full evaluation of the widgets in use is necessarily a longitudinal process and is ongoing.

Evaluation at Analysis and Design Stage

Although the primary stakeholders of this study are the students, the teachers and supporters of students with disabilities and accessibility experts were also considered as stakeholders. For this reason, it was important to seek informal feedback on the workshops from the participants and partners at Portland and York. Some comments include:

> *'In terms of the workshops themselves, I thought that they were superb. It was great to have the morning to contextualise the aims and objectives and then the afternoon for the participants to be creative and work on specific (and therefore highly relevant) widgets'*

The workshop facilitator at Portland College gave this view of the experience:

> *'The dynamics of the three workshops were all very different, with pros and cons to each. The mix of the audience in York was superb, with ideas being adapted and changed from ISC to FE to HE and vice versa. In complement to this though, specific groups also formed on occasion to produce a level or user-specific app.'*

Feedback from staff at the specialist college also indicated that they enjoyed the control of being authors, especially when there was no need to have the technical expertise to worry about how to produce the widgets themselves.

Evaluation at Implementation Stage

A preliminary evaluation of the widgets has been carried out and initial results confirm that the designers are enthusiastic about their widgets, generally the learning designs have been translated successfully into widgets and they have met the expectations of the designers.

A total of 13 participants took part in the evaluation and evaluated the widgets they have designed. A selection of the feedback and suggestions for further development (some of which has already been implemented) is given below:

Touch Screen Timer widget:

> *'It's excellent! Well thought out. I like the digital display going red during the last 5 seconds'*

Visual Shopping List widget

> *'I like the idea of audio feed back on choice selection and selected items put into basket.'*

Digital Abacus widget:

> *'This is very impressive. Thank you for bringing my idea to creation. The widget works fine and is very close to how I imagined it to work. Could you make the background of the application transparent so the user can see the other 'open' window behind the abacus?'* (This was implemented).

Sentence Jumbler widget:

> *'First of all let me say that the Sentence jumbler is a really nice idea and I like how quickly it works - no waiting for too long. I think that if I was going to use this with a learner it would be useful to be able to generate more than one sentence at a time for the learner and click jumble and leave them to it for a few minutes'*
>
> *(Dyslexia Tutor)*

The widgets have been widely disseminated and we have already had a request for an adaptation to the Visual Shopping List widget:

> *'When I saw the Visual Shopping List in the JorumOpen listings I knew it was something I should show to the teachers. They like the widget very much and have asked me to try and find out if it can be adapted. Their particular idea is that the teacher would be able to type in weights and specify exact brands, where necessary, to allow the system to be used within*

cooking classes where students visit the catering store to collect their ingredients."

Evaluation at Deployment Stage

A preliminary evaluation of the widgets developed was also carried out, where selected widgets were evaluated by disabled students in practice. These students have not been involved in the workshops and they were give a list of widgets they could chose from to download and evaluate. The data collection method that was employed was a questionnaire that included both rating scale and open ended questions. The students were required to comment on the widgets' functionality, suggest how they would use them, and identify possible adaptations to their design, functionality or purpose. Overall, the feedback for the widgets was positive and the students identified a number of adaptations to the widgets. All of the students found the process of downloading the widget straightforward and easy and only one of the students had difficulties in understanding the purpose of widget.A selection from the comments from the open ended questions is given below:

Spell it widget:

> *'This is great for anyone with learning difficulties when it comes to spelling. As a dyslexic myself, this is a great tool. All you have to do is guess how to begin spelling the word and the widget does the rest for you!'*

Visual shopping list widget:

> *'The widget is quite simple to operate but I would have liked some kind of table with the items on to be generated after the done button is clicked'.*

One-Click timer widget:

> *'I expected a simple and easy to use widget with a basic but usable interface, but I was actually unable to get it working at the beginning. I would have liked the opting of adding multiple alarms'.*

The other student also commented on the interface of the widget:

> *'I would use this timer when working on small tasks –especially in a time critical environment. But I tried clicking and dragging the timer bar but instead it dragged the whole application and I would have liked a solid background to it so it won't conflict with my desktop'.*

External evaluation

In terms of the external evaluation, the intention was to receive feedback from accessibility experts external to the project on the validity of our overall process which is relevant in terms of the participatory method applied. For this reason, we engaged a number of accessibility experts to evaluate the overall process of the WIDE project, in terms of the wiki, widget learning design and implementation method and the widgets themselves. This evaluation covered an evaluation of a sample of three WIDE widgets, an evaluation of the process of developing a widget (from a non developer point of view and from a developer point of view) and an evaluation of the WIDE wiki as a means of supporting the participatory design process (WIDE Project Report, 2010).

In terms of the widgets, the evaluators found that the working versions of the widgets show significant potential in addressing accessibility issues, and matched the learning designs. Regarding the participatory process, the evaluators identified that the wiki-based approach adopted by WIDE offers a suitable basis for bringing together and supporting interested parties to design and develop widgets. Nevertheless they commented that it was limited to supporting the community of practice and the workshop participants, rather than the wider community.

CONCLUSIONS

Linked to the overarching aim of enhancing the e-learning experiences of disabled learners, the WIDE project aimed to apply user-centred methodologies to the design of accessible widgets and to disseminate these widely, in order to promote a participatory approach to designing and evaluating e-learning.

Web 2.0 technologies equip educators with a rich repertoire of services and applications to address this challenge by enabling learner choice and allowing creative decisions about how to best to set learning goals and create learning environments that support those goals. The findings of the WIDE case study demonstrate a need for personalised applications to enhance the learning experience of students with disabilities, they also recognise that although basic widgets are simple for those with some technical expertise to develop, the development of new widgets is likely to be beyond the means of most teachers or tutors. For this reason a set of authoring tools (incorporating libraries of templates, services and APIs and a repository) that would enable academics without technical skills to develop, modify, adapt and share widgets is required.Development of such a toolkit would require extension of the CoP to include developers, content providers, researchers and learning design experts as well as teachers, tutors and students. This represents a significant challenge but would provide a means for a much more extensive CoP to develop widgets tailored precisely to the needs of disabled students, and would make a considerable contribution to emerging models for supporting greater levels of personalisation and customisation of learning for all individuals.

Abstract and Symposium Plan

The rate of new ideas and the multitude of pressures on time poor academics means we have to develop new ways of recognizing innovative ideas worth implementing and supporting, and to consider effective ways of building capacity which have real impact on student learning. This symposium will highlight and consider some approaches to determining the ideas that make a difference in a time of changing demands and changing directions, as well as offering ways of building academic capacity. Ideas and comments will be sought from the audience, and the group will determine the developing "big ideas" from the symposium and the conference more broadly.

This session aims to be interactive and audience led. In the style of ABC's Q and A, the panel members will provide comments and provocations, and then lead discussion facilitated by a chair. Audience members will be able to engage via their mobile devices; using OWL (Open Web Lecture), a new web-based student response system developed by QUT, which blends the physical space with a virtual learning environment to create a live collaborative experience. The format will be lively, provocative and responsive to emerging topics from the conference. The Chair and Panel will strive to create a blended learning environment by demonstrating an effective format and use of technology that engages the audience and stimulates thinking and discussion.

Using log data to investigate the impact of (a)synchronous learning tools on LMS interaction

Steven Greenland
Swinburne University of Technology

This paper presents exploratory examination of LMS log data from ten undergraduate business courses that differ in terms of learning activity design. Data were derived from the Unit Statistics and User Activity functions on Blackboard versions 8 and 9.1, which report the number of student hits across the various LMS applications. The research identifies obstacles encountered when using log data. Findings suggest that the design of learning activities has substantial impact upon levels of student interaction with the LMS. Furthermore the greater the amount of asynchronous learning activities, versus synchronous ones, may generate increased student interaction not just with the interactive applications but with the LMS overall. This outcome is particularly relevant given the correlation between LMS interaction and student results reported in other studies. The research confirms the potential of log data to inform online teaching practice, highlights some of challenges involved and outlines avenues for future research.

Keywords: log data, LMS, synchronous, asynchronous, e-learning.

Introduction

The past five years have seen dramatic growth in online education in Australia, as well as the surrounding Asia Pacific (APAC) region. As illustration, Open Universities Australia (OUA) enrolments increased from 38,133 in 2005 to 130,976 in 2010 (OUA, 2011). Many other well known universities have also joined the e-learning bandwagon, delivering online and blended teaching not only in Australia but to other APAC countries as well. The international delivery mode frequently takes the form of collaborative ventures with locally based institutions such as Kaplan in Singapore.

With the growing use of learning management systems (LMS) in online education (Weaver, Spratt & Nair, 2008) an apparent correlation between level of LMS student interaction and the assessment grade achieved has been inferred by some researchers using log-in statistics (Beer et al., 2009; Macfadyen & Dawson, 2010). Log data provide an indicator of user interaction with the LMS and have the advantage of being non intrusive, readily available and free. However, the downsides include the time it takes to prepare the data into a format ready for appropriate analysis (Black et al., 2008), as well as the fact that log data never fully describe how users interact with the LMS, nor reveal insights into the users experience, both of which may influence the depth and quality of interaction with the learning site (Beer et al. 2008). Furthermore log data do not necessarily track frequency of reading / interacting with learning materials since some students, perhaps those with connection problems or those who prefer paper, may work with downloaded materials. While few institutions have used student access data obtained from the LMS system logs to inform decision making (Beer et al., 2009), the potential for extracting pedagogically meaningful data is becoming more widely recognised (Macfadyen & Dawson, 2010; Yang et al., 2010).

One potential avenue for log data research concerns the ongoing debate about the use of synchronous versus asynchronous approaches in online education (e.g., Cheung & Hew, 2010). Synchronous live online chats are structured by a moderator and may be text based discussion threads, as well as audio or video discussion using software such as Elluminate. Recordings of the live debate can be posted onto the LMS after the synchronous session to provide students unable to attend the opportunity to observe the interactions. Advantages of these live chats have been discussed widely (e.g., Luck & Whiteley-De Graaf, 2004). They are perhaps most popular since they provide instant responses and feedback between students and teachers.

Many researchers and educators view asynchronous online discussions as playing a crucial role in online learning. Asynchronous discussions are mainly text based. The key advantage over synchronous tools, is that they do not require a presence at a particular ‘time’ and ‘place’ and hence students may revisit this environment as often as they like at their own convenience. Kim and Shaw (2009) conclude that online discussion promotes collaborative problem solving and discovery-oriented activities. Another advantage is the ability to foster student-peer interaction (Rochester & Pradel, 2008). According to Lee (2005) use of discussion boards also helps students to learn to respect and appreciate the opinions of other participants. Birch and Volkov (2005) found that the use of discussion boards allowed students to achieve a range of cognitive and social learning outcomes, and to develop some important graduate skills.

Given the strengths of synchronous and asynchronous approaches supporters and detractors can be found for each; both among teaching staff and students. Some online educational researchers recommend utilising both delivery formats (e.g., Greenland & Ho, 2010; McDonald, 2006). This paper describes exploratory research examining LMS log data from business undergraduate units that employ varying degrees of synchronous and asynchronous learning activities. After presenting the methodology and results, the potential implications for pedagogy design, as well as LMS service providers are discussed.

Methodology

Data were derived from the Unit Statistics function on Blackboard 8 and the Summary of User Activity function on Blackboard 9.1, which report the number of user hits on the various LMS applications. Units examined in this exploratory research ran between 2009 and 2011. Those selected vary in terms of the degree of asynchronous and synchronous learning activities involved in weekly lesson activities. They are classified as being either synchronous (using text based live chat as the main learning activity), asynchronous (using text discussion threads as the main learning activity), or as combining a mixture of synchronous and asynchronous activities. To serve as a constant one unit was run in the three different learning activity modes across different study periods. For units using synchronous discussion recordings of the transcripts were posted to the LMS after each live chat session.

Challenges of using Blackboard log data

The log data downloaded from Blackboard enable the mean number of hits per student to be calculated for each of the selected units. While such data are fairly simplistic in nature a number of challenges were encountered in their retrieval and are outlined below:

With the Blackboard LMS, if user interaction and the number of hits are to be recorded, the track statistics option must be manually set for the various applications for each unit. While this was done for the units investigated in this paper, if a unit convenor does not do this when constructing the unit learning site, or simply forgets to set this option for just one of the applications, then the data are rendered unusable and cannot be compared against other units. Ideally an LMS should have tracking statistics enabled automatically for all applications; otherwise potentially valuable information is lost.

While log data remain available for the duration of the unit, the Blackboard LMS purges log entry data shortly after the unit is complete. Consequently if data are not downloaded immediately after the unit is finished then the information is lost.

Currently the unit statistics relating to interaction with the LMS are separate from the grade centre. If analysis of LMS student interaction against student performance is required then two separate data sets must be merged manually. This adds significantly to the time required and hinders investigation of this rich data resource.

Another limitation with the Blackboard log data reporting system is not being able to drill down into and separate the information. The user activity data include those for non student users such as tutors, administrative and IT staff, as well as students who enrolled but did not actually complete the unit. For this study the data therefore had to be manually cleaned or filtered in order to examine LMS activity specific to students who had completed each unit. While non student users can be deselected during the data download process, enrolled students who had not completed the unit had to be first identified by matching against the separate grade centre output and then manually deleted from the data file. This is time consuming, especially so for larger units with several hundred or more students.

The validity of Blackboard's log data is open to debate. Data presented in Table 1 in the results section are from Blackboard 8 only. With this version there are minor inconsistencies within the unit reports for the total number of hits recorded. Total hits vary depending upon which section of the unit statistics report is used. As illustration for unit F the total number of hits reported in the initial "Access / Application" section of the output is 21365. However a later section of the output report "Access / Day of Week" gives a total number of hits as 22488. For the Blackboard 8 unit statistics, examined in this research, variations of between 2% and 5% were observed in the total hits across all the units studied. Blackboard does insert the following caveat at the top of the unit statistics report "Due to the way statistics are collected, not all totals are consistent", but offers no further explanation. For the sake of consistency, in this research only the hits within the "Access / Application" section were examined for each unit. Nevertheless, any apparent inconsistencies in the statistics reporting function of Blackboard raises concern about the validity of using these LMS log data.

There are significant differences between Blackboard 8 and 9.1 and this year Swinburne University adopted the upgraded version, which offers greater functionality to users. This research had planned to include a greater number of courses using additional 2011 unit data. However, comparison of the output from the two Blackboard versions reveals that 9.1 reports a much higher levels of user interaction with the LMS. This is perhaps logical given its greater functionality and also explains the much greater time that it takes for the 9.1 LMS to perform the unit statistics analysis and produce the output; over 20 minutes for units with several hundred students. Given the apparent higher levels of LMS interaction we cannot yet make valid comparison between levels of unit use across the different versions Blackboard. However, this may be possible once data have been established across a larger number of units. A more significant reason for not reporting any Blackboard 9.1 log statistics in this paper is the much greater inconsistencies observed between the total number of hits reported in different sections of the user activity reports. As illustration across five 2011 Blackboard 9.1 units examined, the number of hits reported in the "Access / Application" varied by between 20% and 60% compared to the total hits in the "Access / Day of Week" section. While discrepancies of the order of a few percent may be more easily overlooked clearly differences of this magnitude cannot be. Furthermore, the unit activity reports from Blackboard 9.1 do not include the caveat regarding inconsistencies in the totals. At the time of writing feedback from Blackboard on this issue is still pending.

Results and discussion

Table 1 presents the log entry details for over 1200 students taking ten online business units. The average or mean number of hits per student has been calculated for different applications for each unit.

Online course or unit	Live chat main learning activity	Thread & live chat activities	Thread only learning activity	Total students	Total hits interactive application areas**	Mean hits interactive application areas**	Total hits all application areas	Mean hits all application areas
A - SP2	✓			53	2536	49	NA	NA
B	✓			15	751	50	2197	146
C	✓			31	803	26	4622	149
D	✓			19	1380	72	3705	195
A - SP3		✓		176	19988	114	32311	183
E		✓		77	11823	154	20195	262
F		✓		81	12547	154	21365	263
A - SP4			✓	85	17833	210	25589	301

H			✓ *	343	161910	472	215377	628

* Assessment component linked to participation in thread discussions
** Collaboration & discussion board application hits combined for interactive application hits

Table 1: Log statistics for student hits by unit and learning activity delivery mode

The 'mean hits' columns in Table 1 suggest that the level of online unit interaction varies considerably depending on whether synchronous or asynchronous communication tools are used. Indeed the frequency of student visits to learning sites is much higher for asynchronous than synchronous tutorial discussion. This higher frequency of hits is also evident across most areas of the learning sites, and not just those in threaded discussions. As a constant, unit A was run using each of the three different learning activity modes across different study periods. This is perhaps therefore the strongest indicator that the (a)synchronicity of a unit's learning activities determines the level of student LMS interaction. Intuitively this outcome makes sense in that students would use asynchronous activities more often since this is a major affordance of this approach. Furthermore when students enter the LMS to check development in the thread discussions they are also likely to visit other applications.

Conclusion

While the total number of students studying the units examined in this exploratory research is large, the sample of different courses involved is narrow. Nevertheless, the log data analysis supports the hypothesis that course activity design in the virtual learning environment has a strong influence on how students interact with the learning management system. Furthermore, it appears that units with more asynchronous learning activities may correspond with greater levels of interaction. This increased access appears to occur not only with the interactive areas of the LMS but across all application areas. Given that others studies confirm links between level of LMS interaction and results, this finding could have important implications for teaching practitioners wishing to design courses that encourage maximum student interaction with the LMS, and thereby contributes to the ongoing debate on online education surrounding synchronous versus asynchronous delivery.

This study is specific to one LMS, but underlines the potential for, as well as some of the challenges of, using Blackboard log data to inform teaching practice. The study may therefore assist e-learning teachers, as well as LMS service providers in terms of prioritising the development of more effective log data reporting capabilities. Further research involving a larger sample of units, as well as using other LMS platforms such as Moodle, might seek to confirm or otherwise the tentative findings and patterns discussed in this exploratory study.

Over the past decade, teaching and learning in virtual worlds has been at the forefront of many higher education institutions around the world. The DEHub Virtual Worlds Working Group (VWWG) consisting of Australian and New Zealand higher education academics was formed in 2009. These educators are investigating the role that virtual worlds play in the future of education and actively changing the direction of their own teaching practice and curricula. 47 academics reporting on 28 Australian higher education institutions present an overview of how they have changed directions through the effective use of virtual worlds for diverse teaching and learning activities such as business scenarios and virtual excursions, role-play simulations, experimentation and language development. The case studies offer insights into the ways in which institutions are continuing to change directions in their teaching to meet changing demands for innovative teaching, learning and research in virtual worlds. This paper highlights the ways in which the authors are using virtual worlds to create opportunities for rich, immersive and authentic activities that would be difficult or not possible to achieve through more traditional approaches.

Keywords: virtual worlds, VWs, Second Life, OpenSim, engagement, VWWG

Introduction and Background

The use of virtual worlds (VWs) for teaching and learning in higher education has gained increasing popularity over the last several years. As Salmon (2009) observes, it is not surprising that some early adopters of virtual world (VW) technology initially used these environments as replications of activities that could perhaps more easily and appropriately be undertaken using traditional teaching and learning technologies. However, VWs have the potential to extend traditional web based online curricula by providing an online space in which students, represented by their avatars, can learn, create, explore, gather information and collaborate in a safe environment that supports experiential learning activities (Wood, teaching and learning). These environments are increasingly being used for a range of activities including presentations, discussions, role-plays, simulations, historical re-enactments, laboratory experiments, games design, creative arts, machinima, virtual tours and career planning. Levine (2010, online) supports this view, noting findings that investigate how educators view VWs today, ‘Contrary to statements that virtual worlds are passé … among educators, interest continues to be strong or growing’.

In 2010, 21 members of the Virtual Worlds Working Group (VWWG) contributed to an ASCILITE paper titled ‘Australian higher education institutions transforming the future of teaching and learning through 3D virtual worlds’ (Gregory et al., 2010) in which they provided a snapshot of the ways in which they were using VWs to transform their teaching for an unknown future. Since that time there have been several important drivers that have influenced the ways in which institutions are responding to changes in the wider policy environment. The first of these drivers relates to the need for institutions to increase their capacity to offer flexible learning environments to meet the needs of an increasingly diverse student population in response to the Australian Government's widening participation agenda (Gillard, 2009). The second major driver arises from the opportunities afforded by the Australian Government's digital economy strategy, which seeks to ensure that by 2020 universities and higher education institutions will have the high speed connectivity and facilities to offer students and learners who cannot access courses via traditional means, the opportunity for online virtual learning (Australian Government, Department of Broadband, Communications and the Digital Economy, 2011). This paper provides an update on the ways in which Australian educators who are members of the VWWG are using VWs to contribute to the changes required to respond to these policy drivers through the innovative use of VWs to provide more flexible learning environments for an increasingly diverse student population. The contributions by the 47 authors of this paper reporting on 28 Australian higher education institutions provide further evidence that supports Levine's (2010) observation that the use of VWs in teaching and learning in higher education continues to increase in number and in scope.

Australian higher education institutions working with virtual worlds

The VWWG was constituted in November 2009 with 12 members from the institutions forming the DEHub research consortium: University of New England, Charles Sturt University, Central Queensland University, University of Southern Queensland and later in 2010, Massey University. In 2010 membership was expanded to all Australian higher education institutions and by mid 2010 the numbers had grown to 24. Due to growing interest, in late 2010, New Zealand educators were invited to join. The numbers currently stand at over 170 members from Australian and New Zealand higher education institutions (HEIs). The members of VWWG come from many different disciplines, specialties and expertise and use a variety of VW platforms. Second Life (SL) remains the most popular platform although the numbers using SL started to decline after the discontinuation of educational discounts to SL customers (Nelson, 2010). The work of the VWWG encompasses a variety of areas. Group members collaborate on research projects, papers, in-house seminars, presentations and also work with students across institutions. The VWWG epitomises what many higher education institutions are striving to achieve, collaboration that permits students to receive their education from the 'experts' in the field. Australian institutions represented here provide an overview of how they are using VWs for teaching, learning and research and changes that have occurred over the past 12 months since this snapshot was last reported.

Methods
A call was sent out to Australian members of the VWWG to contribute to the paper. Authors were provided with the proposed Abstract as to complete a survey, using Qualtrics, to provide consistency and gain insight into the way the authors, whose case studies are reported in the subsequent sections, are using VWs. The 47 authors represented in this paper responded to the call for submissions and this is their story. Analysis was undertaken by examining the type of virtual world each institution used, how long each institution had been using virtual worlds, the disciplines that were using virtual worlds, the number of students at each institution using virtual worlds and queries in relation to challenges and successes in using a virtual world in their teaching and learning. Themes from responses were identified and collated and are discussed in the Analysis and Discussion section.

Of the 28 VWWG Australian institutions reported in this paper, 25 are using SL, 14 Open Sim and 7 are using other platforms, such as Vastpark, iSee, Unity3D, Quest Atlantis and three customised VWs for their own needs. There are a variety of disciplines using VWs, with the most dominant in Education (22), Health (15), Business (12), Science (7) and a range of other disciplines (25), including history, art, sociology, law, engineering, architecture, visual and performing arts, tourism, hospitality, construction, languages, pharmacy, social and behavioural studies. There are approximately 200 students per HIE studying through a VW. The following snapshots represent recent experiences from Australian HEIs utilising various VWs for teaching, learning and research. This illustrates the diverse range of activities being conducted and collaborated by educators, students and researchers as well as their collective experiences. Following the snapshots is a cross-sectional analysis of the various institutions, providing ideas of what worked for various institutions and what the future may hold in relation to VWs. The snapshots are to provide potential users of virtual worlds with a reference guide.

University of New England (UNE)
UNE ventured into VWs in 2008 following the creation of the Education Online Headquarters in SL as a space for teaching and learning in the prior year (see http://www.virtualclassrooms.info). To date, over 500 education students from UNE have experienced SL for virtual tours and excursions, guest lectures, role-play, web quests, basic building and scripting, round table discussions and for fun (Gregory, 2009). Several research projects have

been conducted culminating in an Australian Learning and Teaching Council (ALTC) grant led by UNE and in conjunction with Charles Sturt University (CSU), Australian Catholic University (ACU), RMIT, Curtin University and the University of Hamburg to establish VirtualPREX, professional experience role-play for pre-service teachers with peers and bots. In other fields, students in Pharmacy and Social Work programs are using videos (machinima) and role-play scenarios created in Open Simulator (OpenSim) as part of the Social Work Pharmacy Interaction Contextualization Experience (SPICE). This DEHub funded collaboration between UNE, CSU and James Cook University is creating lifelike, immersive, communication experiences for students with input from industry and is researching their effectiveness to improve learning outcomes.

University of Western Australia (UWA)
The UWA SL presence was launched in 2009 focusing on teaching, research, art, architecture and machinima. Classes have been conducted in several degrees and with international lecturers (Canada, US, Denmark) through SL. Teaching through SL to offshore students in Singapore commenced in 2010. Partnerships have been signed with The University of Texas, San Antonio, for cooperation in Teaching and Art. In architecture, the building creators have created models for the Office of Facilities Management for long term campus planning. An international 3D Architecture Design challenge was held 2009-2010 to provide a design for the Cultural Precinct Flagship building. With Visualisation Research, initial tests have been conducted across many fields including nanotechnology, chemistry, physics, and mathematics, allowing for actively working on 3D data sets with collaborators around the world. Across arts and machinima, the art and machinima challenges have seen prizes up to L$1,000,000 (AU$3,777), some of the richest in SL, and have attracted some of the most inspirational creators in SL from around the world. Close to 1,000 entries from more than 40 nations are received over a year.

Curtin University (Curtin)
Since 2008 Curtin University academics have used SL across a range of disciplines and for different purposes. A key undertaking was the establishment of a representation of some iconic buildings and Student Central from the Bentley campus to be used as a virtual information portal for finding information about courses, faculties and services, as well as for contacting Student Services. The School of Nursing and Midwifery established a virtual wound clinic to allow students to engage in a series of activities relating to wound management and patient interaction (in partnership with Kings College London). The School of Science has been using Michael Bulwer's 'Life on an Island' in Quantitative Biology classes to create very authentic and engaging assessments. Staff and students in Curtin Business School have also conducted teaching and learning projects within SL. The School of Information Systems has used SL to facilitate a role-play assignment, involving buyers and vendors in an international collaboration with Molde University College in Norway. In 2009, an informal 3D MUVE (multi-user virtual environment) Special Interest Group was established for a more formalised and collaborative approach to teaching and learning activities in VWs.

Victoria University (VU)
Educators at VU have been deploying VWs since 2006. Initially working in SL and Teen Second Life. VU's VW activities have focused on increasing student engagement in the VET sector (construction, hairdressing, multimedia, building design) and piloting the use of VWs within the VicHealth-funded Avatar and Connected Lives projects. In 2009 VU's main project team moved to OpenSim and has since run projects using versions of OpenSim hosted externally, on local networks. In 2009 the team also began work on its flagship web-based learning management system called PushLMS. This system allows teachers to enter multiple choice or yes/no question sets that appear inworld when triggered by avatar actions. In 2010 the team used PushLMS to build a virtual unsafe construction site where students triggered questions by exploring and clicking on unsafe workplace practices. Monash University's Pharmatopia has adopted PushLMS, an open source system, trialing undergraduate students in the Bachelor of Pharmacy.

University of Queensland (UQ)
The Foundation Year Business Island in SL (moving to OpenSim) gives students access to a virtual trading environment. Operating as managers within eight businesses, students are able to implement strategic plans and compete with other businesses while receiving guidance from teachers and leaders within the business community. In Education, SL is used to demonstrate the features and possibilities of VWs to pre-service teachers. Mathematics and Statistics use a custom built web based 2D world, 'The Island' to simulate a virtual population consisting of towns, households and individuals. This supports teaching in experimental design, epidemiology and statistical reasoning. Religious studies use 'The Religion Bazaar' (Farley, 2010) that has buildings from a variety of religions to teach first year classes and for supervising distance postgraduate research students. In Pharmacy a virtual compounding dispensary has been built allowing students to practice pharmaceutical calculations. This is located on the Pharmatopia islands in SL (moving to OpenSim), a multi-institution collaboration using a shared practice model where each school develops and shares a simulation. The

Faculty of Health Sciences is planning a virtual medical facility for immersive scenario based learning where interdisciplinary teams collaborate on patient treatment plans from emergency care through to rehabilitation. It aims to develop clinical, communication, problem solving and teamwork skills.

University of Adelaide (UniAd)
'Getting a MUVE On' based in the History discipline aims to evaluate a re-creation of eighteenth-century London in SL. It was used to illustrate lectures, run inworld tutorials and for the design of learning tasks. Students in the pilot course completed inworld assessments which entailed constructing a display including a critique of historical research they had conducted and writing a reflective journal (Matthews, 2010; Lemmings et al., 2010). Meanwhile the 'Transforming Assessment' island in SL was created as a professional development resource targeted at academics with the aim of improving assessment practice within VWs and other online environments. The SL island and website (transformingassessment.com) showcases approaches to e-assessment across a range of disciplines. Examples in SL (Crisp, Hillier & Joarder, 2010a) include using the Sloodle Chair for quizzes integrating both inworld and web content, Sloodle Awards that provides instant and comparative feedback, a chat logger that links inworld and external participants, QuizHUD with 'touch to answer' exercises and using chat bots (scripted avatar robots) to provide interactive quizzes and simulated discussions (Crisp, Hillier & Joarder, 2010b).

TAFE NSW Western Institute (WIT)
WIT provides vocational training (VET) across 65% of western NSW, including many remote locations. In 2010, funded by the Australian Flexible Learning Framework, a project focused on developing virtual tourism learning experiences to engage young learners, specifically VET students and remotely located trainees. The WIT Virtual Campus is currently utilised by Tourism & Hospitality students for a range of web quests and role-play activities. WIT Virtual Campus was established in OpenSim enabling students aged from 15 to 60+ to access a common space. Learning materials are brought to the Virtual Campus via Sloodle through the Learning Management System (LMS). TAFENSW is part of the Department of Education & Communities (DEC) where policies relating to firewall management practices bar the use of innovative technologies such as teaching and learning in VWs using the DEC portal and intranet. Firewall barriers are the keystone to expansion in the delivery base and WIT are balancing the desire to explore technology use in teaching and learning while maintaining the integrity of the IT systems network.

Queensland University of Technology (QUT)
QUT has been utilising SL to facilitate teaching and learning in a variety of modes since 2007. SL machinima have been used to contextualise legal principles in a number of projects such as Air Gondwana (negotiation skills) (Butler, 2008), Entry into Valhalla (legal ethics) (Butler, 2010) and The Sapphire Vortex (criminal liability, responsibility and procedure). All utilise detailed sets created on QUT Island. These projects are testament to the ability of machinima to make real world connections to otherwise abstract principles and to create cost effective learning environments that are both engaging and challenging. QUT Island also provides synchronous learning in both architecture and interior design. Students have used SL to obtain an introduction to 3D modeling and as a simulation of the built environment in creating landscape architecture while others have been involved in the creation of the QUT Space Station, which requires the design and construct of a complex microgravity environment reflecting not only community, connection and inhabitation but also physical expression. Students of advertising, marketing and public relations have also used SL to experience VW immersion and to appreciate 3D implications for marketing including branding, public relations, advertising and sales perspectives (Mathews & Bianchi, 2010).

University of Ballarat (UB)
In 2009 UB created an online SL presence and purchased its own island, including the creation of an online campus which houses interactive lecture theatres, meeting rooms, University promotional literature and specifically built research orientated simulations for different schools and associated academics. Critical Life is a simulated emergency room (ER) to expose nursing students to possible real life scenarios. First created in 2008 Critical Life has since been expanded upon and refined to encapsulate six different scenarios focusing on common ER crises. Critical Life has found to be a valid and embraced environment in which student nurses found it to be a highly beneficial to simulated exposure and also team-based learning. In 2009 the Virtual Stuttering Support Centre (VSSC) created a multi-story building - a hub of self-support for people who stutter (PWS). The VSSC conducts PWS support groups, presentations and meet with other interested people. Members are encouraged to verbally communicate in a safe and supportive environment.

Monash University (Monash)
Monash University Behavioural Studies department first piloted a lecture in SL in 2007. Although technically challenging, the inherent potential of the platform encouraged the lecturers to expand their use of SL as a teaching environment. Since 2009, Digital Selves, a final year subject, has been offered, focusing on equipping students with theoretical and applied knowledge and experience of the implications for identity, privacy, communication, teamwork, commerce and community that are affected by digital mediation. In 2008, the Faculty of Pharmacy and Pharmaceutical Sciences developed a virtual laboratory in SL where students could learn how the pharmaceutical industry manufactures tablets and also the role of ingredients in shaping a tablet's physical properties. The virtual laboratory is a safe learning environment that students can access anytime. The development of the virtual laboratory led to an international collaboration of 12 schools of pharmacy in which each school develops a learning activity on the 'Pharmatopia' island. Chinese Island is designed to complement traditional classroom-based learning with task-based, contextualised learning in a high fidelity virtual environment of Chinese language and culture. Learning on Chinese Island encompasses a range of inworld learning activities, from realistic task-based scenarios, to role-play, quests, the making of television chat shows and news-desk reporting.

Charles Sturt University (CSU)
The School of Information Studies built the CSU-SIS Learning Centre on Jokaydia in SL in 2009, a customised facility to support the teaching of distance education (DE) courses (Hay & McGregor, 2010). Library and information management and teacher librarianship subjects use SL requiring students to complete a number of learning activities inworld. DE students are encouraged to attend inworld discussion sessions hosted by faculty, guest speakers or student presentations; join a range of professional and educator groups; attend professional development activities; visit a range of libraries, university campuses, professional and education spaces; and meet with their lecturers for individual consultation (Gregory et. al., 2010). An evaluation of academics' and students' experiences using SL was conducted in 2010 (Hay & Pymm, 2011) with general consensus from both students and staff that the provision of teaching and learning experiences in SL is very worthwhile. In 2011 staff are exploring new ways to support teaching, research and professional development activities in the CSU-SIS Learning Centre. In the design of energy efficient buildings, students from the School of Education have made good use of Google SketchUp's 'geo-location' feature to place virtual buildings onto a site where it is subjected to simulated sunlight at designated times of the day and year. Using this virtual environment, students walk through buildings and to assess according to their incorporation of passive solar design principles.

Deakin University (Deakin)
Deakin supports a cohesive digital simulations program that includes VWs to encourage flexible, student-centred and accessible teaching and learning. Ubiquitous etechnologies support augmented reality and virtual simulations (Grenfell and Warren 2010) to enhance work related learning (Devlin, Coates & Kinzie, 2007) enabling students to access learning content. In 2007, the building of the Arts Education Centre on Deakin Island in SL began. Later, Criminology, Nursing and Occupational Therapy precincts and an introductory skills development zone were established. To promote greater collaboration, three islands were merged to form a single integrated virtual campus. Currently, undergraduate students, undertaking an elective art subject, are immersed in elearning artifacts embedded within the Deakin LMS system and in virtual and real world art studios. Students move seamlessly from text based content, still and moving images, audio and movie clips, located in the LMS and inworld to real time studio activities using traditional media and techniques or digital image manipulation software. Collaborative learning is experienced and students conduct inworld presentations of their artworks, culminating with a virtual exhibition of artworks in the art gallery in SL.

University of South Australia (UniSA)
UniSA has been active in VWs since 2007. Trials in the use of VWs for health science role-play simulations, experiential learning, defence simulations, performing arts and games design have been widely disseminated (see Fewster, Chafer & Wood, 2010; Fewster & Wood, 2009; Gregory et al., in press; Gregory et al., 2010; Wood, 2010a, 2010b,). Findings suggest: a) students put effort into virtual learning experiences providing they can see the direct relevance between learning activities and their future career aspirations; and b) students studying externally are more positive about the potential of VWs than students studying on campus. The School of Communication, International Studies and Languages is extending its teaching and learning activities with a focus on enhancing and supporting the development of students' career skills in areas such as journalism and professional communication. UniSA is currently developing a virtual careers centre using OpenSim, which will provide students with access to a wide variety of written and multimedia based career learning and information

resources. UniSA is also developing a range of interactive scenarios to better assist students identify and articulate their employability skills.

MacICT Virtual Worlds Project – NSW DEC and Macquarie University (MacICT)
The MacICT project assists classroom teachers in primary and secondary schools to develop curriculum-specific units of work using OpenSim. The objective is to develop programs which maximise student learning outcomes and cyber-citizenship, through engaging students in design and construction activities in the VW. Programs involving sculpture, sustainability, learning spaces and architecture have been completed, covering Visual Arts, English, Mathematics and Human Society and Its Environment. Each program aims to engage students in design tasks with real-world implications, for example designing students' ideal learning spaces for a location at their school. Project evaluations have found that the design and construction activities in the VW can: facilitate students' understanding and application of concepts and design processes; support development of spatial awareness; be highly engaging; encourage collaboration and team work; and enable design resolutions that students are proud of by allowing rapid visualisation and refinement of design ideas.

University of Canberra (UC)
In 2008 the Faculty of Information Sciences and Engineering (ISE) acquired land in SL (Telework, Telework Space, UCISE and UCISE Project). The two Telework regions are largely used for research into virtual work environments and sustainable VW ecosystems and as a platform for scripting and demonstrating artificial intelligence applications (Campbell et al., 2007; Cox & Crowther, 2008; Cox, Crowther, & Campbell, 2009). The Telework regions are also used to support postgraduate research training and projects. It hosts examples of interactive art and artificial intelligence. The underwater environment located in Telework Space is rich in free-roaming artificially intelligent objects. ISE subjects utilise the UCISE and UCISE Project spaces in SL and focus on construction of objects, scripting, land management and practical applications of VWs to industry. Students have the opportunity to acquire high-level skills in building and scripting complex objects (see Ryan, 2009, for an example of student work). In 2011 ISE established a 16 sim OpenSim grid.

University of Tasmania (UTas)
At UTas post-graduate students are exploring the potential for VWs in their own teaching contexts. Students engage in ethnographic research of the textual, discursive and social literacy practices occurring across a range of new media spaces including VWs and other social networking sites. In particular, English teachers and their classes are exploring how complex, esoteric and poetic concepts of texts can be constructed and examined critically in VWs. The site of Virtual Macbeth is being used for research with several secondary English classes. Classroom management is being used with teachers in Australian schools who need to demonstrate a capacity to engage and manage the behaviour of pupils in order to be effective leaders of learning. These skills are not easily practised in the university setting and are often acquired by default during professional experience placements. Trials in SL with pre-service teachers taking the role of students have stimulated development of OpenSim, enabling social exchanges to be private, replacing volunteers with 'bots' to improve learning efficiency.

University of Southern Queensland (USQ)
USQ was an early entrant into VWs in the Australian context. In 2005, the Advanced Learning and Immersive Virtual Environment (ALIVE) project began at USQ, with the aim of providing easy to use, Web3D elearning content development tools for educators (de Byl, 2009). The difficulties and high cost associated with creating a bespoke 3D environment became obvious and given that environments such as SL were emerging, the project was discontinued. Given impetus by this earlier work in 3D environments, USQ hosted a virtual careers fair in SL in 2008. In 2009, the careers fair was held in Exit Reality (McIlveen at al, 2009). USQ has positioned itself at the vanguard of VW use in higher education. In 2007, the first sim in SL provided housing to a variety of immersive teaching activities relating to Law, German language learning, Australian literature and education. In 2011, a second sim was created to explore the restorative possibilities engendered in Indigenous and virtual environments. USQ's exploration of this space continues with the development of an in-house OpenSim grid. National and international projects are being formulated in Unity3D, Minecraft and Kitely.

Griffith University (Griffith)
Griffith School of Education has used a variety of VWs since 2007: the Appalachian Educational Technology (AET) Zone; their own SL island and Quest Atlantis (QA). The School is currently developing VWs in OpenSim, MineCraft and Cryengine. In SL pre-service teacher preparation experience different simulated classroom teaching environments, comparing spatial arrangements and availability of arrangeable space for individualised, collective and collaborative learning. They also explore how student and teacher stereotypes (via avatar role-play) can influence teaching practice (Zagami, 2010) and create collaborative constructions in virtual environments to improve understanding of peer communication that increase complexity and creativity. Arts

education concepts are taught via virtual excursions, performances and installations to prepare students to use VWs in primary and middle years to meet curriculum goals through QA and to participate in international multi-university online projects to develop understanding of the effectiveness and challenges of collaborative online projects. Postgraduate courses use VWs as examples of educational technologies in AET and SL, enhance online course discussions in SL and compare various VWs for achieving curriculum goals (Zagami, 2009).

Southern Cross University (SCU)
In 2009 SCU Interaction Island was purchased. In 2010 Commerce Town was developed to support teaching scenarios in programs in the School of Commerce and Management, Law and Justice, Hospitality and Tourism and Education. The buildings on this island represent a range of business premises and have been realistically constructed to facilitate role-playing and teaching scenarios (Phillips & Ellis 2011: Jacka & Ellis, 2011; and Jacka, Logan & Ellis, 2011). The School of Education has been active in its use of Commerce Town for pre-service teacher courses in visual art, science and technology and learning technologies. In 2011, DBA Island has been constructed to support the International Doctor of Business Administration Program. The students and staff come from throughout Australia and overseas so the SL platform provides an ideal way to bring them together. In 2012 a fourth island is under consideration to allow for facilities to be constructed to expand teaching and role-play scenarios in additional courses in the School of Education and the School of Nursing.

Royal Melbourne Institute of Technology (RMIT)
In 2009, researchers in the School of Electrical and Computer Engineering developed a virtual TV studio learning environment in SL (Neville, Burton, & Burnett, 2010) aimed for use in courses taught at both the Melbourne and Ho Chi Minh City campuses. A significant component of these courses is the practical experience. Students learn to design and create multimedia content, use advanced audio/video editing, mixing tools and the RMIT TV studio. The RMIT Vietnam campus does not have a TV studio facility, thus the SL virtual studio mirrors the City Campus TV studio aiming to help bridge the facility gap and enable student collaborations between the two campuses. The City Campus TV studio is a fully operational facility and with avatar interactivity in SL, the virtual studio mirrors the studio and control rooms (and communications/feeds), props, cameras, and DMX lighting rig with static and intelligent lights. Currently being integrated into LMS coursework repositories using Sloodle for alignment with course material, students can communicate with teachers and student peers, keep a record of their studio setups for class sessions and save the 'film' that they have created in the virtual studio for assessment. Trials using the virtual studio are ongoing with local students to obtain feedback on its effectiveness before deployment across both campuses.

University of Western Sydney (UWS)
UWS has both developed the technology of VWs and utilised that technology for education purposes. Research has been focused on technology for electronic trading, cultural studies, tourism and emulation of processes in hospitals. Core technology is based on the integration of formalized social norms, Artificial Intelligence and VWs. The Westopia Island in SL is used by the School of Computing and Mathematics for teaching, developing new methods of human-computer interaction, game technologies, social informatics and professional communication. A SL project, Uruk, recreates humanity's first city in ancient Mesopotamia and simulates daily life using Artificial Intelligence (Bogdanovych et al. 2010). Education uses it for experiments in creating immersive teaching materials, in particular, history. Students learn about the daily life in Uruk by 'living' there and interacting with virtual 'inhabitants' who are agents aware of where they 'live', hence the history learning happens through interacting with them. The team has developed technology for controlling avatars via a motion capture suite for applications in sports, health informatics and tele-health.

Swinburne University (Swinburne)
Swinburne's Koala Island in SL caters for two groups of students, on-campus students and Open University Australia (OUA) students. On-campus students have been exploring the VW of Exit Reality alongside SL. However, the lack of 'virtual life' within Exit Reality has been a constant issue for students and consequently they prefer SL to do their business model analysis. Over the last year there has been an increase in usage by distance and OUA. They have been made up of post-graduate students undertaking IT subjects. These students have been using the island for group discussions for subject related matters and exploring the island together in groups as part of their get to know routine and ice breaking. This has been a new development and is very encouraging given the difficulty surrounding group work involving distance of OUA students. To facilitate these, several cubicles have recently been built and usage of these spaces is readily noted. Despite the growth in usage and popularity of the island in SL there are discussions to move to OpenSim due to funding.

Central Queensland University (CQU)
In 2008, CQU Learning Island opened with a welcome area providing signposts for spaces and events enabling one to teleport directly. Interests were strong initially for usage of SL as the platform for micro-worlds, but there were concerns about the requirements for sufficient bandwidth and computational power for effective use of the environment. Organisational issues impeded the use of SL, with some campuses blocking access at the network level. Issues around cognitive load was also explored by the research team as it had been observed that as users spend most of their time trying to learn how to navigate through the unfamiliar environment, instead of planning, articulating and thinking about their ideas; it was hindering learning. The research interest then shifted to exploring the educational potential of SL machinima and CQU integrated the use of machinima in curriculum and instruction (Muldoon et al. 2008; Muldoon & Kofoed, 2009). In this longitudinal design-based research, machinima were used as an anchor for apprenticeship style learning in the classroom.

University of Sydney (Sydney)
Sydney's Faculty of Architecture is using SL for lectures, demonstrations, tutorials, exhibitions, interactions and discussions where students collaborate on designs, presentation and exhibition and are critiqued by teachers in SL in conjunction with Istanbul Technical University, Turkey and Yuanze University, Taiwan. Being together increased the awareness of others' activities and social presence, which mimics characteristics of face-to-face learning. The Estate USydney in SL facilitates teaching instrumentation, process dynamics and process control concepts in the Faculty of Engineering and IT. Equipment found in oil refineries was built in SL with simulated behaviour augmenting practical learning. A challenge facing this engineering application of SL is interfacing the environment with dynamic simulations that mimic real process behaviour. Students in SL engaged with instructor and peers. International students, with preliminary English skills, favoured SL over local students (Abbas, 2010). A Sydney and Macquarie University project explores the use of educational virtual worlds to develop scientific inquiry skills in secondary school science education. This project uses Unity 3D to design the Omosa Virtual World enabling students to engage in scientific inquiry in biology as they investigate the mystery of a plummeting population of megafauna in a scenario inspired by Australia's unique natural history. Students are encouraged to gather and analyse data to solve the mystery of ecological crisis on Omosa.

James Cook University (JCU)
When developing an on-call hospital ward simulation at JCU, it was considered that the limitations of third party platforms were too restrictive to capture the real world nuances that exist within the communications and interactions of patients and medical professionals in a hospital ward. The lack of control over the technical facilities of the underlying technology also limited the ability for customised data capture for formative feedback and automated elearning assessment. The imposition of available interface options starkly contrasted real world interactions. In response to these problems, the medical ward environment was created using Unity 3D with avatars and medical models created in AutoDesk Maya. Unity 3D offered high resolution 3D graphics with superior performance, networking support, ease of importing 3D objects, terrain builder, audio capabilities, light mapping for realism (reflections and shadows) plus avatar customisation and animation. In addition, Unity 3D provides the ability to read and write from files and to interact with a database. These features provide a basic infrastructure and make data capture for assessment and feedback more flexible. Using Unity 3D a prototype of the on-call hospital ward simulation was developed featuring virtual patients with intelligent conversation system, networked supervisor observation console and time-stamped log files of interactions.

La Trobe University (LaTrobe)
La Trobe's Faculty of Humanities and Social Sciences built an island in SL in 2007, providing a series of learning, teaching and meeting spaces based on LaTrobe's bush campus and the laneways of central Melbourne. An open-air lecture theatre modeled on LaTrobe's amphitheatre and a sandpit and campsite were also provided. Initial uptake from academic staff was slow and depended on individual enthusiasm. A virtual Art Gallery was added in 2008 and is used to showcase student work in photojournalism. The Faculty of Law and Management is about to use the space for mooting classes and projects have been conducted in Nursing and Education.

The University of Melbourne (UniMelb)
Researchers at UniMelb are studying the use of VWs and online games, researching: the impact of voice communication on user experiences in online communities (Wadley & Gibbs, 2010); problems of mutual awareness during collaboration around objects in SL; building and studying networked games that employ 'exertion over a distance'; and the ongoing negotiations of rules and conventions by users of VWs.

Australian Film Television and Radio School, (AFTRS)
In 2006 Esperance was established in SL and used for educational and pervasive game applications through the Laboratory of Advanced Media Production (LAMP) including ‘Thursday's Fictions’ combining art, poetry, real life performance and spiritual exploration. The Graduate Media curriculum uses SL for sound design for games, cinematography, machinima pre-visualization, script development through role-play, VW creation and 3D art as well as hosting mini conferences with international media schools.

Analysis and Discussion

In 2010, the VWWG presented a snapshot on institutions using virtual worlds in their institutions (Gregory, et. al., 2010). At this time, 21 authors from the 22 members of the VWWG contributed to the paper. There has been a rise in popularity with contributions for this paper increasing to 47 authors from 28 institutions. Members of the VVWG were asked a variety questions in a survey to provide current information on what is happening in the Australian VW sector. Table 1 indicates when each institution began using VWs at their institution.

Table 1: Opt in year of using virtual worlds of institutions represented in paper

Year			Institution
1998	UWS	2007	Griffith, LaTrobe, Monash, QUT, Swinburne, UNE, UniSA, UB
2005	USQ	2008	CQU, Curtin, Deakin, UC, UQ
2006	AFTRS, Sydney, VU	2009	CSU, RMIT, SCU, UWA
		2010	JCU, MacICT, UniAd, UTas, WIT

As can been seen in Table 1, UWS began using VWS in 1998, however, the uptake from other members of the VWWG has been since 2005 with the use of immersive VWs such as Second Life. Table 2 outlines key responses in the survey from the authors of these institutions on two questions; the key things that they are using VWs for and the unresolved challenges that VWs present.

Table 2: Institutional responses on experiences of teaching, learning and research in a virtual world

Question	Key responses
List three key things that you are doing in a virtual world	Research; providing students with virtual experiences unavailable to them; meetings; tutorials; social media; inter-professional education; ethical decision-making; experiential learning, collaboration; role-play; simulation; guest lectures’ web-quests; excursions; tours; scenario based training; building; scripting; authentic assessment; programming behaviour of avatars and objects; interfacing VWs with motion capture suits and cybergloves; design and implement distributed sports games
What are your current biggest unresolved challenges	Technical and financial support; bandwidth; acceptance; accessibility; lack of vision; preparation of materials; many people on the one sim at the one time; timetabling, learning curve

What do virtual worlds provide or enable?

The themes that emerged from content analysis of the snap-shots and survey responses were assessment, collaboration, communication, engagement, stepping stones and simulation and that the following discussion elaborates on the responses according to each of these identified themes. Virtual worlds provide ACCESS where ACCESS is an acronym for assessment, collaboration, communication, engagement, stepping-stones and simulation.

Assessment – While not necessarily its key strength, VWs provide a vehicle for assessment. An advantage of setting assessment tasks in a VW is that marking can be automated. They are also a useful venue for conducting assessment tasks when other barriers are in play. Typically this would involve physical barriers (for example a disability) or a geographic barrier. UniAd have established 'Transforming Assessment' island in SL as a resource for academics to improve VW assessment activities, as well as Curtin, using 'Australis 4 Learning'.

Collaboration – the VWWG itself is an exceptional example of collaboration. Members have produced over 300 articles on VWs. VWs play an important role in overcoming the tyranny of distance and as a result, members report increased collaboration and networking not only between students, but also between staff and especially with international collaborators. Phrases such as, 'the ability to develop and participate in cross-disciplinary, cross-institutional and cross-border research and collaboration' is one that most members of the VWWG relate to. Many institutions report international collaboration on research and teaching (expert international guest lecturers are invited to present at various institutions to students at little or no cost). Where else but a VW could a student be provided with interaction from these experts? To the authors' knowledge, to date there have not been any similar collaboration internationally with the exception of academics from New Zealand universities who are part of this group.

Communication – At one level communication is at the heart of what VWs do. Collaboration and simulations, for example, highlight the power of VWs as a synchronous communication tool. VWs have a special role in asynchronous communication. VWs have been used as a vehicle to demonstrate student work and machinima is often used for demonstrations or for students to submit assessment tasks. QUT and CQU have used machinima as a vehicle to make real world connections to otherwise abstract principles. Higher education institutions and institutions generally have, to some extent, used VWs to communicate something about who they are. For instance SCU have designed a virtual presences mirroring their physical presences, Deakin highlighted their strength in the visual arts by their appealing use of colour and light.

Engagement – While engagement is a multidimensional concept, the authors generally acknowledge that engagement exists when students have a sense of energetic and effective connection with the activities they are undertaking, for example, one author commented that there was a 'high level of engagement in virtual world-based activities by young male construction students'. Many members reported increased engagement of students. This may be reflected in increased participation, increased interaction and a greater willingness to share. VWs provide an increased sense of 'being there' that has resulted in increased student perception of their engagement and is correlated with increased student grades. VWs play an active role for engagement (or at least the student perception of engagement) effective (feelings) behavioural (observable actions or performance), cognitive perceptions and beliefs (Finger & Asun, 2001). Possibly the most significant venue for engagement is in simulations, and it is so important, that it has been allocated a category of its own.

Stepping-stones – Virtual worlds provide stepping-stones to overcome barriers. These barriers may be physical, cultural, geographic, psychological or even financial. For example VWs have a role in reducing performance anxiety, supporting international students and students with a disability to increase confidence and participation. VWs have been used to create a virtual support centre and this provides skill development opportunities as much as it provides solutions for the users. Several institutions reported that they used VWs to eliminate many of the social and cultural barriers to engagement in the classroom.

Simulations – Simulations provide a rich tapestry of opportunities for educators. VWs have been used as mock trials, a virtual pharmaceutical compounding dispensary (UQ) pharmaceutical virtual laboratory (Monash) and defence (UniSA, CSU, USQ). Even at a less complex level VWs enable educators to add lifelike contexts to learning and to contextualise otherwise abstract and dry education principles.

Challenges for Virtual Worlds

The learning/inconvenience curve and physical constraints (bandwidth and computer hardware) are two significant impediments to VWs. 'Lag' (slowing of the computer) is a common problem experienced when many (upward of 30) students share the one virtual space. Lag is a function of bandwidth and computer capabilities (especially RAM). Some VWs cope with lag better than others. The learning/inconvenience curve comes about because software needs to be downloaded on a computer and then a set of basic skills needs to be acquired (movement and communication). Often this whole process could be achieved within two hours with good guidance. Experienced 'gamers' would do it much quicker. However, this is just to function at a basic level. Often these impediments are overlaid with institutional constraints (e.g. firewalls) and financial constraints. Much VW work has been initiated on minimal budgets by motivated academics. This effort must be leveraged by budgets and institutional support to deliver the higher dividends offered by VWs (e.g. simulations).

How have these challenges been overcome?

Some members of the VWWG reported that they upgraded computer equipment in laboratories enabling better access for on-campus students. However, they were not able to provide this support for off-campus students. When students took on this expense themselves they found it improved their VW experience. When technical support was available during initial workshops many issues were overcome. Staff were provided with professional development immersive learning experiences and research and professional literature on VWs to give them a better understanding of the virtues of VWs. Members of the VWWG also worked with their staff to identify potential applications of VWs. Support from senior management assisted in overcoming many barriers as this support enabled academics with the financial and time required to provide VW experiences to their students and other staff. Staff also reported on the development of appropriate non-player characters to assist with teaching and designing of pedagogy, lessons and tasks. Collaboration with other institutions provided professional development, guest lecturers or join forces during lessons with students. Many members report that they used external assistance such as machinima and non-player characters to assist with their lessons. As VWs are currently undergoing dramatic change, many members of the VWWG are migrating to other VW platforms.

The above list of successes of using a VW in teaching, learning and research outline how a VW could be used as an educational tool. The HEI discussions demonstrate that virtual worlds have been used for various learning scenarios and across a variety of disciplines. VWWG members were asked to respond to how their teaching or use of a VW has changed. Grant Meredith, UB, encapsulates the many responses: 'Our teaching using SL has extended more towards multi-discipline awareness and education regarding the possibility of VWs being integrated into curriculum. We are continuing this education process at the moment to step up embracement and experimentation. We are continuing to experiment and evaluate group interactions and meetings within VWs'. These challenges and solutions can guide those planning to undertake teaching and learning activities in VWs.

Future and Conclusions

VWWG members see the future application of VWs, as outlined by Helen Farley, USQ, as: 'I think browser-based VWs will become more common and make OpenSim and SL more accessible by circumventing current ICT security issues associated with these platforms. Gesture-based computing will similarly become more commonplace. Gaming consoles such as Kinect and Nintendo Wii will push this trend. In turn, this will lead to activities supporting authentic learning and become a cost-effective way of providing authentic learning experiences at a distance.' There are many similar experiences outlined in this paper. Although some institutions may be a couple of years ahead of others, they have all learnt from each other and new users are able to learn from the more experienced users. Higher education teaching, learning and research are changing and educators need to embrace the opportunities that VWs provide to ensure their students receive the best possible immersive and engaging education that Australia can provide. 47 authors reporting on 28 institutions have demonstrated how the Australian higher education sector are addressing continuous changing demands by utilising VWs into their teaching, learning and research repertoire of resources. Not all Australian universities were represented in the paper and due to limited space, an in-depth analysis was not possible and content analysis was thus also limited by number of responses by members of the VWWG. The changes from the 2010 snapshot (Gregory, et. al., 2010) to this snapshot highlight the emergence and collaboration that has taken place in the VWWG. Further research should be undertaken to provide readers of a more in-depth analysis and cross-section of teaching, learning and research currently being undertaken by the HEI across Australia.

Acknowledgements

The authors would like to acknowledge members of the DEHub Australia and New Zealand Virtual Worlds Working Group (VWWG) who have made it possible for this collaboration to take place.

Many pre-service teachers currently undertake their professional experience with insufficient knowledge and confidence to handle unexpected teaching situations. VirtualPREX explores the experiences of 72 pre-service teachers who undertook a teaching role-play in a virtual world. The researchers discuss this opportunity for pre-service teachers to utilise new methods and avenues in a virtual world to both supplement their learning and undertake preparation for practical experience. Participation by pre-service teachers in role-play enables them to test and develop a better range of professional skills and acquire confidence in, and more realistic awareness of, their skills before being placed in real-life classrooms. Presented in this paper are the findings from a pilot of this study and pre-service teacher reactions to the role-play activity including whether they felt that it was helpful in preparing them for their upcoming professional experience placement.

Keywords: virtual worlds, Second Life, professional experience, pre-service teachers

Introduction

The term VirtualPREX (virtual+professional+experience) has been developed as part of an Australian Learning and Teaching Council (ALTC) grant where pre-service teachers role-play professional experience in a virtual world. Researchers from six institutions, University of New England (UNE), Charles Sturt University (CSU), Curtin University (Curtin), Australian Catholic University (ACU), Royal Melbourne Institute of Technology

(RMIT) and University of Hamburg (UHH), are exploring assessment of virtual professional experience using peers and bots (virtual world robots or non-human characters). An overview of the results of a pilot study, where pre-service teachers experience teaching their peers in the virtual world of Second Life (SL), is presented in this paper.

Key literature, background and rationale for the study

A virtual world is an online presence that imitates real, or fantasy, life in the form of a personal presence through someone's avatar, their alter ego, a graphical representation of themself in the virtual world (Gregory, 2007). SL is one of over 200 virtual worlds (Gregory et al., 2010) and was chosen for the project as UNE, Curtin and ACU already owned a joint island in SL, Australis 4 Learning (C. Dreher, Reiners, H. Dreher, & N. Dreher, 2009), where five of the project members already taught. This was an ideal place for pre-service teachers to practise their teaching as a classroom and playground was already established on the island.

A strong professional experience component is acknowledged as essential to teacher preparation (Darling-Hammond, 2006; Hastings & Page, 2007; Keogh, Dole & Hudson, 2007; Smith & Lev-Ari, 2005) and school-based practice sessions to allow pre-service teachers to apply pedagogical theories in a realistic teaching situation are integral to all pre-service teacher education programs in Australia. Nonetheless, research has shown that, in Australia, as elsewhere, pre-service teachers often enter the workforce ill equipped for their professional role (Ferry, et al., 2004). This unpreparedness no doubt contributes to the rise in attrition rates when pre-service teachers undertake professional experience (Sim, 2006) and the 45% of newly recruited in-service teachers who resign or burn out in their first five years of classroom teaching (Ingersoll, 2001). However, and increasingly, accessibility to meaningful professional learning experiences, located in the field, is becoming limited due to significant increases in enrolments in teacher education and no subsequent increase in field placements (Barbousas & Nicholson, 2009). Furthermore, pre-service teachers who are located in rural and regional centres, or are in a low socio-economic bracket, and therefore have difficulty funding significant travel, are further restricted in the access to quality professional experiences (Abbott-Chapman, 2011). Therefore, there exists a mismatch between the value of learning in professional settings and the opportunity to undertake such learning. By supplementing traditional professional experience placements with a model of professional learning in the virtual world, concerns about accessibility may be partially addressed. Through a virtual model, pre-service teachers are no longer restricted by travel times nor availability of schools to practise their teaching prior to undertaking professional experience.

In considering the learning that occurs in a professional placement there is the inevitable matter of inconsistency in experiences and thus concerns about ensuring a defined and expected level of quality in the pre-service teacher experience. As universities move further towards an accountability agenda (Massaro, 2010) there is a growing need to better manage the quality of learning, and hence professional experiences. Here quality is being distinguished from standardisation. The idea of a standard professional experience is an enigma, however, quality experiences should be aspired to for all pre-service teachers. Quality professional experiences provide a diversity of experience within a variety of learning settings and interaction in complex classroom environments. At times where a pre-service teacher is successful in being placed into a school, they are put into environments that are less than supportive, or limit their opportunities to take a leading teacher role, for example team teaching with other pre-service teachers. Whilst pre-service teachers do learn from such experiences there is no consistency on how this learning can then be related to the teaching skills that they have learned in their course, nor are they afforded the opportunities to develop the range of professional skills required of a professional teacher. SL provides a highly immersive environment (Dalgarno & Lee, 2010) where pre-service teachers can interact and become fully engaged in their experience as practice teachers.

Where issues of accessibility are not problematic, the experience of a virtual world can further supplement the development of professional skills necessary to ensure successful achievement in the real world professional experience. Formative assessment, explicitly designed to promote effective learning, has a powerful influence on educational outcomes, supporting both high-quality learning and empowering lifelong learners (Crisp, 2008). VirtualPREX is being designed and implemented to provide pre-service teachers with experiences that reflect the complex, diverse and multi-faceted nature of a teacher's role in classrooms, schools and the broader community. The virtual world learning experience provides the ability for an instructor to create spaces and experiences that permit pre-service teachers to engage in the variety of experiences needed to develop across all elements of teaching practice. Unlike real world professional experience, the virtual world is somewhat controllable by the instructor ensuring that a pre-service teacher's experience can test them in particular circumstances and environments better suited to their current learning position. For example, a pre-service teacher who has difficulty in managing the disruptive student could potentially be able to access a virtual world experience where the other variables of the classroom are managed to permit a focus on the acquisition of this skill. Over time, the other elements could be varied slowly approaching a more definite simulation of the real world environment. Through constant practise and feedback, and the variations possible, a pre-service teacher will potentially be able to assess and evaluate their skills, developing these further before eventually applying them to the real world.

Locating practice within a virtual world creates a space of safety for the testing of ideas and practices which would otherwise be socially difficult in the real world (Campbell, 2009). The anonymity afforded by a virtual world environment may permit pre-service teachers to engage freely in practice and test their strategies to deal with the situation without a fear of errors being attributed directly to them. Also the errors of judgement, whilst providing valuable feedback, have no long-term impact on actual students in the real world. For example, a beginning teacher often has difficulty in assessing the levels and types of responses that should be given to certain behaviours of students. An inexperienced teacher may therefore either over-react or under-react to particular circumstances, with each level creating a range of possible consequences, such as impacts on student self-esteem. What may be regarded as small incidents in the classroom can have a long-term impact on the learning of students. Therefore, there is a need for emerging teachers to have developed proper responses to a range of classroom behaviours, but this should occur in a safe environment both for the teacher as well as the students. The virtual world presents such a possibility. Inherent in a progressive introduction of emerging professionals to the world of practice is one of the complementary development of professional identities and therefore the empowering of pre-service teachers to make mistakes and learn from these. As the pre-service teacher interacts with the virtual world professional experience it is anticipated that they will come to better understand themselves as teachers and therefore be able to draw from these experiences in responding to challenges in the real world.

Although providing these positive outcomes, it is acknowledged that limitations continue to exist in the use of virtual worlds as teaching and learning tools. Primarily, these limitations come through the ‘opaqueness’ of the technology and therefore the limitation of the ability of pre-service teachers to fully engage in this space. This critique refers to the problems associated with access to high-speed Internet which permits ease of use of the virtual world, particularly from a distance, and limits on the experience of pre-service teachers working in these environments. Despite Prensky’s (2001) claims of the emergence of the digital native there still exists a substantial percentage of the current university student population who do not regularly interact with role-playing games (RPGs) or virtual worlds. Therefore pre-service teachers can make cynical responses about the use of these tools for meaningful learning (Gregory & Masters, 2010). VirtualPREX, as well as developing a useful professional experience for pre-service teachers to engage with, needs to also consider the usability of such tools for these purposes, as well as developing the capacities for pre-service teachers to competently and willingly engage with these.

Research design/methodology

Aims and objectives

The primary aims of the project are to:

- Assist pre-service teachers in acquiring a better range of professional skills and confidence before being placed in a real life classroom;
- Provide diverse professional experience options for pre-service teachers;
- Create awareness about virtual worlds as a pedagogical and social networking tool, and;
- Compare different methods of interaction to enhance pre-service teacher learning and teaching.

The primary outcome of this project will be the development, implementation and evaluation of VirtualPREX with structured learning experiences for formative assessment (Crisp, 2008). The project as a whole will consist of four phases as follows:

- During Phase 1 (which has been completed),
    - a focus group session was conducted with experienced teachers to identify the aspects of teaching practice to be included within VirtualPREX role-play scenarios, and;

- a pilot study of pre-service teachers undertaking a role-play activity using the initial version of the VirtualPREX environment was undertaken.
- During Phase 2, the VirtualPREX environment will be further developed, including the creation of bots (short for robots; being avatars completely controlled by the computer) representing school students exhibiting particular problematic behaviours;
- During Phase 3, the VirtualPREX environment will be trialed with cohorts from each of the partner institutions; and
- During Phase 4, data collected during Phase 3 will be analysed and the results reported in various formats.

The project has adopted an action research methodology involving action, analysis, reflection and re-action (Kemmis & McTaggart, 1988) and, in keeping with good evaluation practice, mixed methods will be used (Babbie, 2007) to ensure accuracy and alternative explanations (Stake, 1995). There is an ethical need to confirm validity of the process and this will be done through triangulation (Tellis, 1997), using multiple sources of data (Yin, 1994). Reported in this paper is Phase 1, which focused on developing a model of an effective, replicable approach to using and evaluating a virtual space for teaching and learning. Ethics clearance for Phase 1 was obtained from the University of New England Human Research Ethics Committee. Phase 1 consisted of two stages as follows:

Stage 1: A focus group of eight (8) experienced teachers was formed to gather the participants' experiences of key pedagogical issues and classroom management problems that they encountered during their careers. The focus group session was recorded and transcribed to provide material to be used to design the virtual world role-plays.

Stage 2: 72 pre-service teachers undertook role-play activities in an immersive virtual classroom environment, prior to undertaking a real professional experience placement. The pre-service teachers undertook teaching role-plays with their peers role-playing primary school students. After completion of the role-play activities students completed a survey. The interactions during the role-play were also captured as text, video and screen shots to allow for analysis as part of the project as well as for the purposes of reflection and evaluation by the pre-service teachers and their lecturers. The sequence of events for pre-service teachers in Stage 2 were:

- Undertake dispersed days in schools;
- Undertake VirtualPREX role-play in a computer laboratory, and;
- Complete a survey after the completion of the role-play focusing on the usability of the virtual environment and students' prior experience with virtual world technologies.

Environment and role-play design

SL was chosen as the platform for the research project as UNE, Curtin and ACU already owned a joint space for their students. Four new virtual classrooms were created on the Australis 4 Learning island in SL (see Figure 1). 40 primary school student avatars and 8 teacher avatars were created for the role-play. The primary school student avatars were small, looked younger and were dressed in school uniform. Four computers were set up to record the VirtualPREX classes (video, screen shots and text). These recordings will be used to create machinima (in-world video footage) to create tasks for self, peer, formative and summative assessment. They will also be used for reflective tasks.

Five 2-hour workshops were completed with 72 pre-service teachers, ranging in number from 9 to 19. The workshop groups were divided into smaller groups of between 6 and 8 pre-service teachers each, depending on the size of the group. Each workshop began with a reminder to students on how to control their avatar in the virtual world. Students had received a prior 2-hour workshop learning how to navigate and interact with the virtual world. The reminder presentation took approximately 15 minutes. The presentation put VirtualPREX in context. It was also to remind the pre-service teachers of a few tips and tricks on how to use SL. Pre-service teachers were then handed their avatar's name and their student role-play scenarios for the workshop and each person received the choice of a male or female teacher to role-play.

The intention was that all students would have the opportunity to play the role of the teacher as well as the role of a primary school student. Specifically, each pre-service teacher was to present a 7 minute teaching episode or idea focusing on their preferred Key Learning Area (KLA) to a virtual classroom of their peers, followed by an interactive peer feedback session. The pre-service teachers were expected to develop teaching strategies to control their class and to draw upon relevant resources such as readings, texts, web resources and study guides to inform their role as the teacher. Peers, role-playing primary school students, were given their role during the workshop. These roles were designed drawing on the description of student behaviours that emerged during the focus group discussions. The role-plays that the students received were colour coded – pink/orange were "good" and blue/green were "naughty" students (see Table 1). This assisted in keeping the pre-service teacher on task as to which role to play and to easily swap if needed.

Figure 1: Pre-service teachers undertaking VirtualPREX role-play activities

Results

Focus group sessions

Eight experienced teachers and principals attended a focus group discussion and the session was recorded and transcribed. From this discussion, role-play scenarios for the primary school students for VirtualPREX were developed. The focus group thought that the following were the most common types of students you would find in a typical classroom:

- Getting up and down, wandering around and never still
- Calling out all the time
- Know-it-all – beyond putting their hand up, they just want to get the answer out
- "Goody goody" – just want to please the teacher all the time – going beyond being helpful
- Behaviour Disorders – may not have taken medication
- Tattletale – dobs on fellow students
- Over-achiever – knows answers beyond capabilities of other students – potential of becoming bored
- Noisemaker – tapping the desk, whistling, humming
- Under-achiever – does not understand and is always asking questions
- Does not pay attention and is always asking what is going on or getting the teacher to repeat things
- Slow learner – always behind in their work and often off-task
- Language Disorders – these children may be a bit slower
- Dominator and defiant – takes the teacher on
- Non-responsive student – withdrawn, sulky, non-cooperative, disengaged
- Eye-roller
- Attention seeker

After the focus group meeting the researchers chose the most common behaviours of students in a typical classroom and these are outlined in Table 1. Students were to role-play either a "good student" or a "naughty student". It was decided that, as these were first year pre-service teachers, they would not be given any student role-plays that were beyond their capabilities to control as a teacher.

Table 1: VirtualPREX role-play characters

"Good Students"	"Naughty Students"
Good students – ideal students in a	Walk around the class a lot, stop and talk to other
Good students, but do not understand	"Dob" on peers and continuously interrupt
Teacher pleasers	Stay up too late and nod off
Know-it-alls	Withdrawn – will not say anything or do anything

	Other things on mind – looking out the window and Back chatters who are rude to the teacher

Initially there were meant to be more “good students” in each class than “naughty students” to provide the “teacher” with the opportunity to focus on strategies to involve the “naughty students” in their lesson. However, this did not always eventuate depending on the number of pre-service teachers in the workshop.

Role-play participants

All 72 students who participated in the role-play activity were first year on-campus pre-service teachers at the University of New England. 61 were female and 11 were male. They were all aged below 26 years of age and came from various locations around NSW when they were not living on campus (none indicated in the survey that they lived in a capital or non-regional city, 55% indicated that they lived a regional town or city, and 37% indicated that they lived in a rural town or on a rural property). Students were asked a variety of questions in relation to their ICT skills prior to commencing university studies, their use of ICT online tools and knowledge of virtual worlds prior to commencing studies. 70 of the 72 respondents indicated that they used the Internet daily and 70 indicated that they used social networking tools either daily or several times per week, with 68 of the 72 respondents naming Facebook as the social networking tool they used regularly. However, less than 10 of the respondents regularly played networked or 3D games or regularly used virtual worlds. In fact, 37 respondents indicated that they never used virtual worlds and 25 indicated that they did so infrequently. When asked about their skill level in relation to the use of virtual worlds 30 indicated that it was very low, 20 low, 18 average, 4 indicated that it was high and none indicated that it was very high. Clearly, the profile of the students suggested high usage of computers and the Internet, but very low levels of experience with virtual worlds and related technologies.

How the role-plays progressed

A number of technology problems were encountered in the first workshop. Firstly, people and surroundings in the virtual world did not ‘rezz’ (come into focus), and secondly, and most importantly, for two of the groups, group chat did not work properly. Even though the group chat failure only affected two groups, everyone was affected by the revised strategy, which had to be applied quickly to keep the momentum going. The revised strategy, which was kept for all future workshops, was that the workshop participants were divided into only two groups (instead of four) and used the virtual classrooms that were far enough away from each other so that local chat could be used. After they had completed their seven-minute lesson, the pre-service teacher had to log off and change roles back to a student and the next teacher had to log on and begin their lesson. At the same time the role-playing students had to switch their student persona from “good” to “naughty” and vice versa. This process was repeated until everyone had had a turn at role-playing the teacher. In the first workshop, some students did miss out on role-playing the teacher because of lost time working out a strategy to overcome the technological problems. In all workshop teachers were asked to type in capital letters in local chat to differentiate the teacher’s talking from that of the students.

Pre-service teacher views on the role-play activity

At the conclusion of the role-play activity, pre-service teachers were presented with a survey and were asked a series of questions about their experience of the role-play activity and their views about its value. Table 2 shows a summary of their responses to a question asking them to rate the degree to which they found the activity Confusing, Difficult, Irrelevant, Interesting, Easy to use, Useful, Boring, and Enjoyable. Only 40% of the students found the activity useful with 24% undecided, possibly indicating that the value may not have been clearly communicated or perhaps that students did not see practicing in a virtual world as a valuable way to develop their teaching skills. Interestingly, of the 10 students who did not play the role of the teacher, 9 indicated that they found the activity not useful, and of the remainder, only 28% indicated that they did not find the activity useful. This suggests that playing the role of the teacher is the most important part of the activity from the pre-service students’ perspective. Encouragingly 61% found it interesting, with 18% undecided. A sizable minority (31%) found the activity confusing with 28% undecided and 29% found it difficult with 15% undecided, indicating that additional support or preparatory training may be required. Another factor which was mentioned in a later question was the difficulty and confusion experienced by the role-playing teacher in keeping up with the typed conversation in the virtual world.

Table 2: Overall perspectives on the role-play activity

Response	Not at all ←					→	Extremely	Mean
	1	2	3	4	5	6	7	
Confusing	7%	15%	18%	28%	20%	8%	3%	3.75
Difficult	13%	20%	23%	15%	20%	8%	1%	3.41
Irrelevant	17%	29%	13%	14%	13%	9%	6%	3.26
Interesting	1%	7%	13%	18%	30%	14%	17%	4.77
Easy to use	0%	9%	16%	26%	23%	24%	3%	4.47
Useful	3%	13%	21%	24%	23%	10%	7%	4.08
Boring	13%	17%	19%	30%	7%	10%	4%	3.49
Enjoyable	1%	7%	24%	24%	11%	19%	13%	4.44

Pre-service teachers were asked to state the best and worst thing about the activity. In describing the best thing, a number of students noted that it was entertaining; a number highlighted the novelty of the experience, while a number commented on the value of role-playing a teacher or particular types of student.
In describing the worst thing, a number mentioned the problem of everybody talking at once. This could just indicate the challenges for novice teachers in managing student behaviour or it may suggest that there are problems in using text chat rather than audio in a simulated classroom role-play. Consistent with this, a number also indicated that having to type made things move slowly and that they found it boring at times. A number also mentioned the difficulties in obtaining control of the class as a teacher, which may in fact be a positive rather than a negative, if in fact the pre-service teachers who were role playing primary school students were doing so in a realistic way.

Pre-service teachers were also asked to name one thing about the activity that could be improved. A number commented on aspects of communication suggesting, for example, that the teacher should be able to use the audio talk function. Others suggested the need for stricter guidelines for the activity and restrictions on avatar actions (for example preventing unrealistic actions like walking on desks).

Using reactive bots to create an interactive classroom

In the Pilot, pre-service teachers engaged in different roles to interact with other human-controlled avatars. As a consequence of the Pilot study, a number of changes were recognised as being useful to ensure the role-play runs more smoothly and effectively in future sessions. First, the current turnaround time to change from one role to another (e.g. teacher to student) was too time consuming as pre-service teachers had to log off and back on. Second, the role-play was only possible if a certain number of human-controlled avatars were simultaneously online and knew how to play their role. The first concern can be solved easily by having *outfits* available that the avatars use to replace their current look (including items like glasses or hats to identify the avatar in the new role). The question of human-controlled avatars and consistency in the role-play can be resolved by the inclusion of bots, which are currently in the development stage. As is common in games, non-player characters or bots will be provided that can fill each role; see also Mahon et al. (2010), Jolie et al. (2011). Major advantages for this approach from a non-technological perspective are:

- Multiple roles for the simulation even if the classroom is used by an individual learner;
- Predefined (scripted) reaction on events occurring in the classroom;

- Re-playing the same scenario multiple times without variations, e.g. in the case of exams where each learner should get the same test and not depend on bad acting capabilities;
- Changeable behaviour of bots using script libraries, that is, the teacher can configure the bots in advance to define certain scenarios including required actions to react to, and observing the experiments, the teacher can interactively manipulate bots to change their behaviour;
- Monitoring is simplified: bot action can easily be recorded and consequently observer is focused on learner;
- Replay of sessions to provide formative feedback.

SL offers an ideal environment to implement an interactive environment that allows monitoring of all events as well as providing bots at a high level of sophistication by using the original avatar technology. Figure 2 shows a schematic of the anticipated framework consisting of in-world and external components. The design is related to performance issues, as a complete in-world control of avatars would be too slow (Ranathunga, Cranefield & Purvis, 2010; Kumar et al., 2008). An experiment involves the following activities:

1. All roles/characters are either assigned to a human-controlled avatar by wearing the corresponding outfit or a bot is initialised by requesting the external server to log in and take control.
2. Configuring the mood, behaviour, event and solution for each avatar. For human-controlled avatars, this is only a guideline, as the software cannot influence the behaviour. Bots, on the other hand, perform based on these settings; e.g. A2 is naughty (mood) and will throw paper-airplanes (behaviour) whenever the teacher's area of observation is not on the student (event) (see Figure 3). Asking the student to draw a picture or keep the area of observation on the student can prevent the behaviour. Note that we plan with single events and actions at this project stage. The configuration board can be in SL (e.g. hidden behind a flipchart that only the teacher can turn around) or on external clients.
3. During the experiment, all events (including chat, movements, actions) are observed by an *object* in SL and reported to the external server for storage and later analysis.
4. The results are exported in different formats (e.g. Excel, websites) and will allow the whole scenario to be replayed by having the server use the information to control all roles as bots.

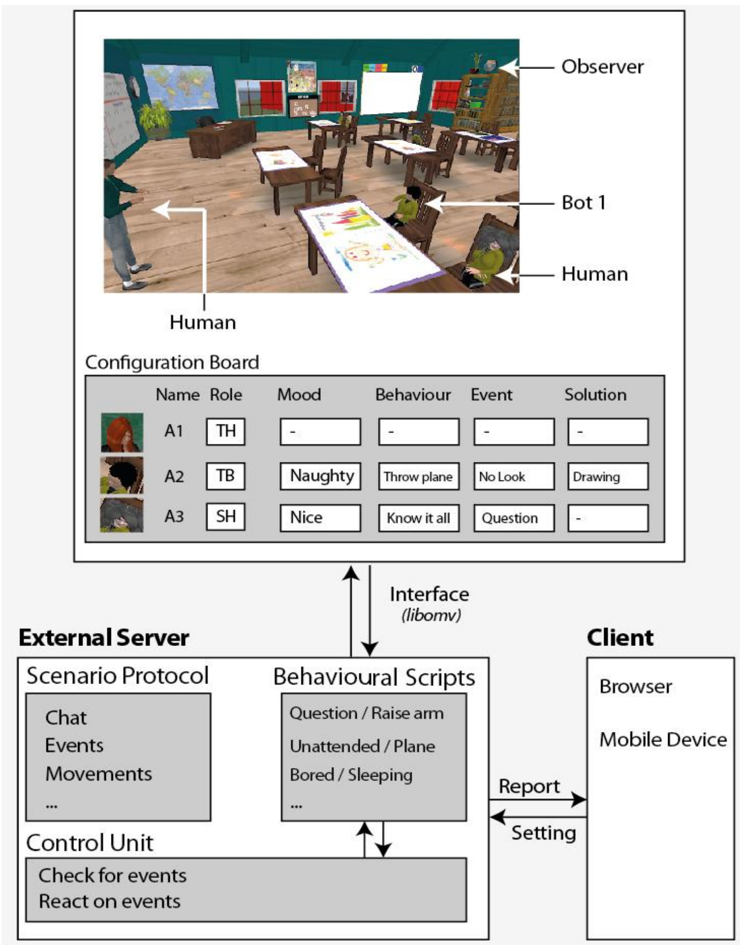

Figure 2: Schematic framework of in-world and external components of bot creation

The implementation uses the libomv-library (OpenMetaverse Foundation, 2011) for communication; thus allowing the usage of other virtual worlds in future projects; see Ranathunga, Cranefield and Purvis (2010), Prendinger, Ullrich, Nakasone and Ishizuka (2011); Gayle and Manocha (2008). The server applications are written in C# (due to the library being available for C# only), the in-world scripting uses the Linden Script Language (LSL). The whole system is kept modular such that scripts and server-client-technology can later be re-used as currently the development of virtual worlds is very fast paced. Over the last two years, several technologies to design and implement bots have disappeared and even though suggestions for standardisation exist e.g. MPML3D (Prendinger, Ullrich, Nakasone and Ishizuka, 2011), there is no final solution visible in the near future.

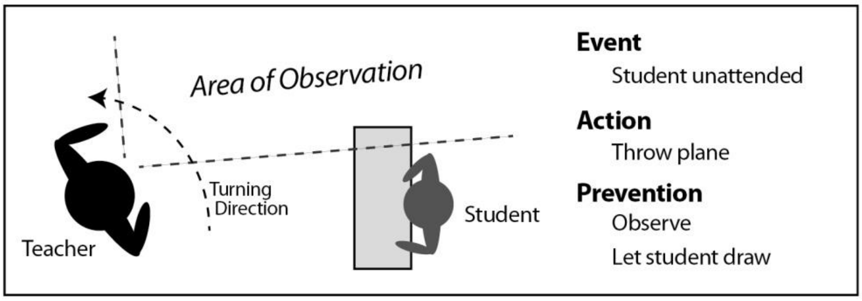

Figure 3: Example for event with teacher avatar and student bot

Conclusion and next steps

Each pre-service teacher was given two role-plays to act out as primary school students (one “good” and one “naughty”). When they had only two roles, after a while, they became bored and over-acted their part (or maybe this is just immersing themselves in their roles). Pre-service teacher feedback was that they wanted more in-depth criteria to act. Consequently, pre-service teachers will be given more roles to carry out. These will be created with the next iteration of the project.

In Phase 2 one component is the creation of machinima (in-world video) of online practice sessions that will be uploaded for viewing. The machinima will then be used as learning aids for self-assessment through reflection, as well as peer/educator formative assessment. Scripted machinima demonstrating best practice will also be produced and made available for pre-service teachers and other academics.

VirtualPREX on Australis 4 Learning will be accessible to members of the Second Life community of educators and all teachers, academics, pre-service teachers and postgraduate students across the higher education sector nationally, and potentially internationally, to use for practising and, researching professional skills. Results of the research will be shared and freely available to the higher education sector through the delivery of conference presentations, production of journal articles and via the virtual world of Second Life through online resources.

Acknowledgements

The authors would like to acknowledge the contribution of the following: Geoff Crisp (RMIT), Heinz Dreher (Curtin University), Deanne Gannaway (University of Queensland) and the Australian Learning and Teaching Council (ALTC) for the grant that enabled this project to come to fruition. Support for this publication has been provided by the Australian Learning and Teaching Council Ltd, an initiative of the Australian Government Department of Education, Employment and Workplace Relations. Abstract and Symposium Plan

There has been much media reporting on the efficacy of virtual worlds for education over the last few years. Some of the claims made are unfounded and not based on empirical evidence. All panel members have been teaching and conducting research in virtual worlds for several years. They will address many of the myths about teaching and learning in a virtual world. The format will follow Jamie Hyneman and Adam Savage's television series, "Myth Busters" ("MythBusters," 2011) to find out whether the myths are "founded", "busted" or "plausible". To date there has been limited research and publications reporting on myths surrounding the teaching and learning in virtual worlds. However, Calani (2010) attempted to resolve the myths around immersion, James (2007) set about resolving the myths surrounding business in *Second Life* and, Hendrich & Mesch (2009), discussed 10,000 reasons why a virtual world will or won't work. This interactive session will seek audience participation in resolving these myths through evidence-based practice. In this symposium we will endeavour to address some of the following myths that have been perpetuated about teaching in learning over the last few years:

- Virtual worlds are not a platform in which one should do business.
- Virtual worlds offer no educational value.
- Anything you can do in a virtual world you can do somewhere else.
- Virtual worlds are too complicated for students.
- Virtual worlds take too long for academics, teachers and students to learn. *Second Life* is really expensive.

- Why not just use Skype instead of using a virtual world for conversations?
- *Second Life* is not scalable.
- You need to be a computer geek to be effective with using a virtual world.
- Virtual worlds won't survive; the 'hype' is over.
- *Second Life* is designed to be all things to all people; thus, it is not good for specialised activities such as teaching and learning.
- There are risks to students, as *Second Life* is all about sex, gambling and entertainment.
- There are too many distractions in *Second Life*.
- Young kids aren't allowed in *Second Life* then why use it with teachers when they can't use it for their own teaching?
- Students with disabilities cannot access virtual worlds.
- Virtual worlds contribute to the 'digital divide' by creating barriers to students from equity groups.

Students’ engagement with technologies: Implications for university practice

The inexorable pace of technological change demands frequent modernisation of learning technologies and services to ensure they support equitable and engaging learning environments. Because of the resources involved, costs incurred need to be carefully weighed up against the potential benefits that upgrades will bring to students and their learning. In order to provide an evidence-based approach to planning, three Australian universities have recently completed a multidimensional survey to gain a better understanding of students’ experiences and expectations of technologies in everyday life and for study purposes. More than 10,000 students responded. Technologies surveyed included established (email, learning management systems) and the more recent Web2.0 technologies (YouTube, Facebook). This paper presents the initial findings and implications they have for the development of technology-rich environments that are equitable, engaging and support quality outcomes.

Keywords: learning technologies, infrastructure planning, student experience

Introduction

Few can deny the pivotal role that technologies play in facilitating learning. Maintaining currency with the latest technologies however, incurs substantial costs to institutions, not only in developing robust technical infrastructure but also in the provision of educational development and support services. Hence, decisions about technologies need to be made with clarity of the potential benefits to students and their learning.

Kuh (2003), in his research on student engagement warns against universities making judgments about policies and practices in the absence of student engagement data or some comparable source of information. The danger of making decisions based on assumptions, rather than evidence, is borne out in research on the net generation, i.e. students 25 years and under. These students are claimed to have digital technologies central to their daily lives (Strauss & Hoew, 2006). However research by Kennedy et al. (2006) challenges assumptions of the digital literacy of net generation students as well as their interest in the use of digital technologies for study purposes. They found that the use of technologies was not as widespread in first-year students in Australian universities as expected. On the other hand, Oblinger & Oblinger (2006) in studies of American students, found that it is the mature-aged students balancing work, family and study who are more likely to be looking to use technologies to support their learning. Although this may have changed in the last five years, it does point to the value of understanding students and their academic and social practices; something that Gibbons (2007) maintains as necessary if students are to be placed at the centre of decisions about services and facilities.

The need to establish an evidence base to support future planning for learning technology infrastructure provided the impetus for three Australian universities – Macquarie University (Macquarie), the University of Western Sydney (UWS) and the University of Technology, Sydney (UTS) – to embark on a project to identify students' experiences and expectations of technologies. This paper reports on the preliminary findings from a survey, developed as part of the project, and also highlights the implications they have for future planning.

The survey

The survey was designed to provide insight into students' current and expected use of technologies for learning and also differences in academic use compared to use in everyday life. The development of the survey drew on several sources of information. The ECAR Survey, a United States based survey developed by Educause (ECAR, 2008), gave a perspective on how undergraduates think about and use information technology. The Great Expectations of IT Survey (JISC, 2008) from the United Kingdom, canvassed students aged 16 –18 considering going to university about their expectations of technology provision. To preserve commonalities with these surveys we used them as a reference point in relation to the scope of technologies and issues to be canvassed. The Horizon Project, a project of the New Media Consortium (http://www.nmc.org/horizon), produces annual reports describing emerging technologies likely to have an impact on teaching and learning in universities. These reports were used to ensure the survey was forward looking, capturing emerging trends. In addition, the work of Kennedy et al. (2008) served as a reminder that not all students have access to, or use the latest technologies, hence we were careful to include the familiar established technologies (email, SMS, mobile phones) as well as more recent Web2.0 technologies.

Overall, the Learning Management System (LMS) (i.e. Blackboard) and 25 other technologies were surveyed: instant messaging, text message (SMS), email, collaborative/conferencing technologies (e.g. Skype, Elluminate), mobile phones for voice calls, mobile phones with internet access, social networking sites (e.g. Facebook, Myspace, Twitter), virtual worlds (e.g. Second life, Active Worlds), blogs, wikis, online multi-user computer games, podcasts/webcasts (e.g. YouTube), social bookmarking/tagging (e.g. del.icio.us, Diigo), software used to create audio/video materials (e.g. Audacity, GarageBand, iMovie), presentation software (e.g. PowerPoint, KeyNote), data analysis software (e.g. spreadsheets and databases), Google docs, e-portfolios, GPS tagging (e.g. Flickr, Picasa, blog), library search engines, internet search engines (e.g. Google, Yahoo), RSS feeds, interactive whiteboards, web development software (e.g. Dreamweaver, Front Page), and tablet computers (e.g. iPad).

The survey comprised 127 questions covering demographics, access to technologies for learning, administration, communication and everyday social and work purposes. Included were four open-ended questions to provide qualitative data about the student experience.

Procedure and results

The survey, open to all students, was delivered online at each of the universities through Voice Project (http://www.voiceproject.com.au/). Invitations were extended through the LMS and the regular avenues for student announcements at each of the universities. The survey was administered during 2010: in April at Macquarie, May at UWS and October at UTS. The combined responses yielded a data set of 10,269 participants: 1104 from Macquarie, 7419 from UWS and 1754 from UTS. Only a portion of the findings that relate to technologies for everyday use and coursework purposes are reported here.

Technologies used in everyday life

Participants were asked to indicate on a five-point scale (Never or Rarely, A few times a semester, A few times a month, A few times a week, or One or more times a day) how often they currently used the technologies listed above in their everyday life, for social and work purposes. The top 10 technologies used a few times a week or more were: internet search engines (93% of respondents), text message (SMS) (92%), email (90%), mobile phones for voice calls (83%), social networking sites (77%), podcasts/webcasts (54%), instant messaging (51%), mobile phones with internet access (50%), library search engines (36%), and Google docs (28%).

Technologies for learning

To explore current and future use for learning, participants were asked, *How often do you, and how often would you, like to engage in the following learning activities that use technologies as part of your course?* The top 11 technologies currently used are shown in Figure 1. The most popular was internet search engines with 90% of participants using them at least a few times a week. This was followed by library search engines (46%), social networking sites for groupwork activities (24%), and podcasts/webcasts created by lecturers (23%).

When these technologies were matched with participants' preference for future use (shown in grey in Figure 1), it can be seen that comparatively more use would like to be made of all technologies, except internet search engines and social networking sites. Two other technologies, not shown in the figure, were also rated highly: tablet computers (e.g. iPads) for information access and contribution (42%) and interactive whiteboards (33%).

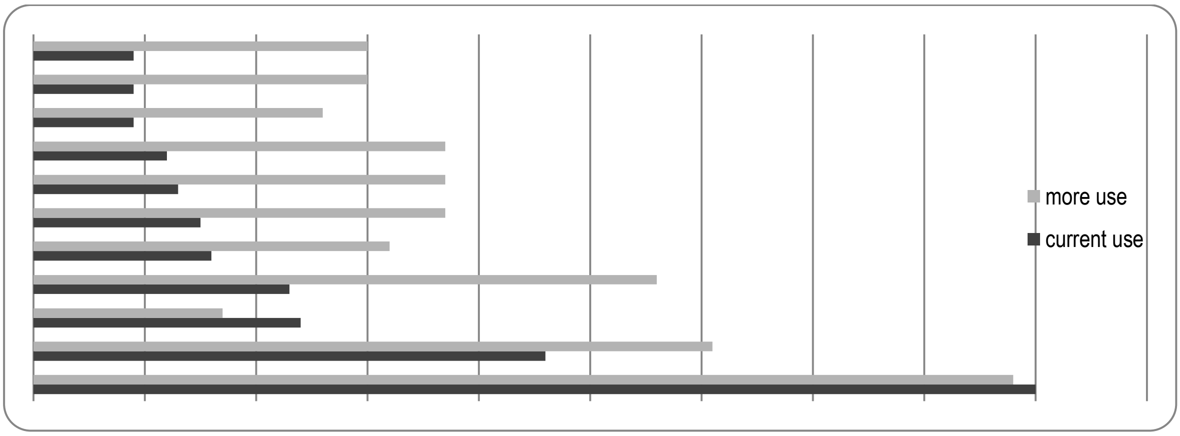

Figure 1. Students' current use of technologies compared with preferred use for learning

With regard to the LMS, participants were asked to indicate their use of 12 tools/functions. Their current use in rank order is: access to content (56% of participants doing so at least a few times a week), announcements appearing at login (56%), access to unit outline (40%), access to lecture recordings (37%), discussions (36%), quizzes for assessment (28%), tracking of progress and grades (26%), mail (22%), quizzes for feedback (19%), submission of assignments (17%), return of assignments (14%), and sharing work with other students (13%). In the future, students would like more use made of all tools and functions, with the strongest demand for lecture recordings with a 27% increase, followed by increases for assignment submission (23%), quizzes for feedback (21%), tracking grades and progress (21%), return of assignments (19%) and discussions (18%).

Web 2.0 technologies

There is quite a lot of speculation about the use of Web 2.0 technologies for learning, particularly applications that are popular in everyday life. Figure 2 shows the current use for social and work purposes (black) and preferred use for learning (grey).

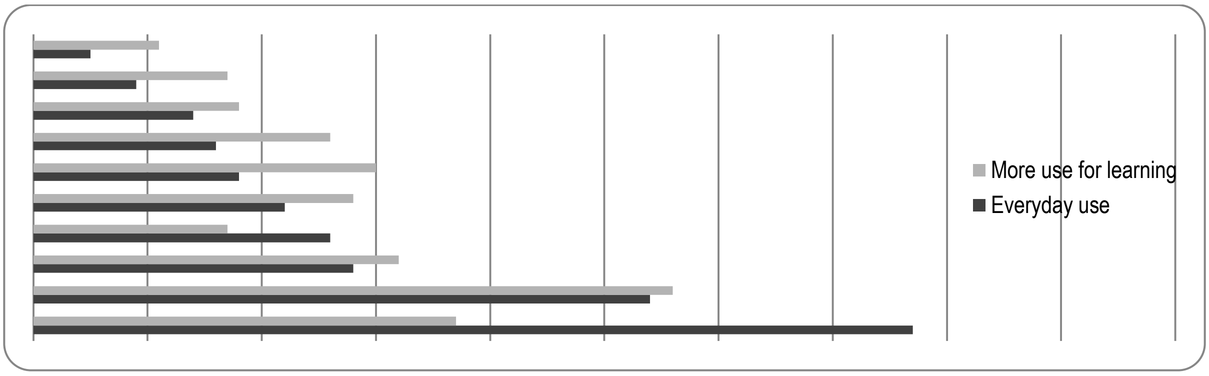

Figure 2. Students' current everyday use of Web 2.0 compared with their preferred use of learning

In can be seen that in everyday life the most frequently used Web 2.0 technology is social networking with 77% of respondents using it at least a few times a week. However, most students clearly do not want more use made for educational purposes, with preferred future use for learning falling to 37%. A similar but weaker pattern was evident for wikis. This was not the case for the other technologies shown. In everyday life, little use is made of virtual worlds (5%), tagging (9%), e-portfolios (14%), blogs (16%) and RSS feeds (18%) with somewhat more use being made of Skype/Elluminate (22%), Google docs (26%) and podcasts (54%). Nevertheless, these technologies are seen to have some educational value and students would like more use made of them.

Implications and concluding comments

The findings presented provide a snapshot of emerging trends. Overall, there is a clear message that students would like more use made of almost all technologies to support their learning. An exception to this is social networking, which is clearly seen as a technology for everyday use. The technologies that are currently used most often for learning are search engines, library databases and e-materials, and the functions in the LMS related to accessing information and resources. For future use, a similar pattern emerges with the strongest preferences being for search engines, access to online content through the LMS, announcements (LMS), lecture recordings (LMS), and podcasts/webcasts created by lecturers, followed by the LMS tools (discussions, access to unit outline, tracking progress, quizzes for feedback and assessment purposes). This suggests a continued focus on the development of the core, mainstream technologies in the university is warranted.

Looking at the comparative differences between current and future use, as opposed to outright rankings, gives an indication of the technologies associated with the strongest demand for increased use. Appearing in this group are mainstream technologies; podcasts, lecture recordings, and LMS tools for assignment submission, tracking progress, quizzes for feedback and assessment. Other technologies in the group reflect an increasing demand for mobility, flexibility in access and synchronous interaction and these are: tablet computers, e.g, iPads, to access and contribute to activities; mobile phones to access and contribute study-related information on the internet; interactive whiteboards to participate in tutorial-based learning activities; and web conferencing, e.g. Skype/Elluminate, to join in remotely to lectures or tutorials.

A cautionary note when interpreting the findings is that students' ratings could be influenced by their current experiences of learning and teaching with technologies; if courses are not designed to encourage new learning experiences and use of emerging technologies, their future potential may not be evident. If the full potential of these technologies is to be exploited, then academics must have the understandings, skills, support and time to enable their effective integration into the curriculum. Students' current experiences of campus infrastructure and support facilities also need to be taken into consideration. Although not shown here, satisfaction levels with these were quite low at all three universities. The reliability of technologies on campus, availability of wireless networks and power points to charge devices, and spaces to use mobile devices, attracted satisfaction levels of between 45% and 49%. Not only could this impact future use, it has serious implications for the present.

Overall, the findings suggest the need for continued investment in core technologies and services to promote more reliable access and effective use. However this should not exclude investment in more recent and emerging technologies, as there is a growing demand and awareness of their potential. Further analysis is taking place exploring the use of the LMS, differences between cohorts (e.g. disciplinary groups, low SES students, international, distance and on-campus students) as well as individual differences (e.g. age, gender). There is also the potential for repeated use of the survey to increase the database and provide a profile of changing usage patterns over time.

Sustaining elearning innovations

Dr Cathy Gunn
The University of Auckland, New Zealand

The challenges of turning funded projects from elearning innovations into sustainable products and services have featured in the higher education literature for more than forty years. Various guidelines and strategies designed to facilitate the process have been developed and tested. Key challenges are identified and critical success factors proposed. Yet the problem persists in more or less original form, suggesting that most of the advice has been lacking in some respect. This paper examines the current raft of ideas and proposed solutions to the problem of sustaining elearning innovations. Preliminary findings from sixteen case studies are presented to see how experience aligns with the guidelines. While the evidence from these cases is not universal, it is does support comment on the usefulness of existing guidelines and a proposal for an alternative approach to sustainable innovation based on this research.

Keywords: elearning innovation, sustainability models, organizational change, project processes

Introduction

Since as early as the 1960s, institutions and governments have promoted the use of educational technology through various strategic initiatives and a funded project model. This model typically offers support for two or three years, and in recent times, the expectation has been that new elearning systems or products will be widely disseminated and self-sustaining by the end of the funded phase. In some cases, second round funding has been offered to projects that can demonstrate initial success, however, this is an exception rather than a rule. Since many funded projects involve research and development for innovative systems, it often proves difficult to meet all the funding body expectations within an externally imposed timeframe. Furthermore, project teams with strengths in research informed design and development may lack the skills for dissemination and to build a business case for ongoing support. As a result, many projects with strong educational potential fail to find the means to continue beyond the funded phase, and a low return on investment is achieved. Apart from some research publications describing the experience, which many teams have limited time to produce, there is no efficient mechanism for sharing the experience gained in the research and development phase. The research described in this paper acknowledges that this problem has existed for many years, and presents a representative sample of literature to track other researchers' analyses and proposed solutions. Case studies were used to explore the practicalities of these solutions, and to identify emergent approaches to sustainable innovation.

The problem with funded projects

In a seminal work on the topic, White (2006) presents a summary of national strategic initiatives that were significant in driving the development of educational technology in higher education in the UK from the middle of the 20th century. As one of the pioneering regions in this field, the UK experience is something others can learn from. The predominant focus on funded projects within major initiatives is noted; along with the Teaching and Learning Technology Program (TLTP) evaluation report observation that 'management support and related investment' are important determinants of elearning project survival beyond the funded stage (HEFCE 1996).

On the matter of management support, White (2006) questions whether national strategic objectives that drive significant investment are well aligned with institutional ones, because with hindsight, local support has been slow, and in many cases, failed to materialize. While the funding council identified its own strategic objectives, it offered no direct help or direction for institutions to develop their own strategies. It acknowledged some of the challenges that might arise, and tried to anticipate the help and support requirements this would generate. In the circumstances, it may be reasonable to conclude that the vague nature of what 'management support' actually means and assumptions about senior management's ability to provide it may be part of the problem. In another study, Duke & Jordan (2008) found 'significant shortcomings in the capability of senior management teams in HEIs to identify and exploit the full strategic potential of technology.'

While funding rounds achieved significant gains in building elearning capacity across the UK higher education sector, from a single institution perspective, the project-based approach showed little success. For example, in six institutions involved in the *Scholar Project*, White (2006) reports that the observed effects may have been a result of changing external circumstances, i.e. the advent of the WWW, falling hardware costs and a general increase in the use of technology, rather than project activities. Little activity continued after the funded phase, and it was difficult to see how this could be maintained in the face of competing priorities such as research and the normal demands of teaching. Some initiatives report higher levels of success, (e.g. Anderson et al 2009). However, low uptake is common, and experience shows the opinion expressed by one participant that 'if it works the faculty will find a way to pay for it' doesn't hold true in many cases; certainly not when locally developed elearning systems and tools are made available beyond the host institution. There were cases where local developments had been adopted for institutional use, but frequency and processes through which this was achieved were not described. White's study also explored alignment of individual and institutional objectives, and concluded that improvement was needed, not just locally, but also for governments and their agencies. A distinction between teaching and research-intensive institutions was noted, as drivers of behavior, structure and management are different. Other researchers make a similar distinction (e.g. Czerniewicz & Brown 2009)

A final point of note in White's (2006) paper is that different capacity building strategies are required for early and late adopters of technology. While it is relatively easy for decision makers to identify early adopters, the challenge is to harness their energy and achievements as sources of systemic change. Both the need for this, and proposed processes to achieve it have featured in the literature for many years, but the success of such attempts has been variable. The question that remains is, what factors contribute to the situation where a seemingly simple process involving creative effort picked up by structure, strategy, policy, procedure and tactics has failed to achieve this objective? The parting comment from White (2006) is that institutions might usefully establish long-term strategic alliances to identify local barriers to change and critical success factors. While this kind of collaboration has run against the grain in a typically competitive institutional environment in the past, the case studies conducted for the current research suggest it is emerging as a practical rather than policy driven strategy.

Why initiatives fail

A high level perspective is offered by Demirkan et al (2010), who note that many elearning initiatives fail where substantial economic investment is required upfront, and the ability to adapt systems and services is limited. The case is based on an industry/university consortia reference model, which is validated through experiences of the Teradata University Network. The reference model addresses basic and advanced sustainability capabilities that integrate partner, application, faculty, student, and elearning service system issues. Validation of the model is by mapping to the literature on advances in elearning service system capabilities. One generally useful product of this validation step is a comprehensive set of capability assessment questions for use by national or institutional elearning initiatives. Broadly speaking, success depends on the ability to sense the environment and reconfigure systems to meet changing requirements; to assimilate or transform them to generate new ones; to manage interdependencies; and to integrate or adapt system elements to suit specific purposes. This high level view of systems and services is clearly important in a rapidly changing higher education environment, yet it is absent from most national and institutional elearning initiatives.

Further support for this perspective comes from a conference of researchers, policymakers, and practitioners focused on ‘scaling up success in technology-based educational improvement’ (Harvard University, 2003). The event synthesized insights from lead researchers working on challenges of transfer, generalization, scaling up, and adaptation of successful educational interventions. Participants included researchers and educators from case study sites, as well as national and state policymakers. The conference provided the opportunity to share insights, and to explore the missing links between theory and practice that undermine promising innovations. In brief, these links related to the need to adapt innovations to local contexts, and contextual factors that are often overlooked in research studies. The importance of a shared vision was noted, along with the increased chance of sustainable change where stakeholders have a practical problem to solve, and an innovation is the solution.

The lack of focus on adaptability and responsiveness to changing conditions is implicated in the failure of major initiatives such as the ‘learning object economy’ (Gunn, Woodgate & O’Grady 2003). Yet these attributes are uncommon in planning and implementation of most elearning projects. The open source community is a notable exception, with a model of adaptability that shows signs of making further inroads into national tertiary sectors.

Conditions for success

To address the barriers identified in various contexts, lead researchers have published frameworks they believe will support general capacity development in elearning, for example:

> If higher education is to meet the forecast challenges of this century, initiatives in elearning will need to encompass more than the current focus on teaching strategies… This article describes a framework for developing the capacity to deliver elearning courses. (Alexander 2001, p247).

Alexander’s framework is representative of initiatives with similar aims, and includes:

- A vision for e-learning at the institution
- A technology development plan
- Development of faculty workload policies which relate to e-learning
- Maintenance of a reliable technology network
- Facility for providing technology support to staff and students
- Market research support
- Faculty development opportunities in student learning, good practice in course design, development and implementation, project management, team- work, evaluation and time management
- Provision of time release for faculty engaged in e-learning developments

There can be little doubt that attention to these factors would help to achieve the benefits identified in an earlier study by Alexander, McKenzie & Geissinger (1998), i.e. improved quality and productivity of learning, improved access to learning, and improved student attitudes to learning through technology. In an article on ‘institutional readiness’ Czerniewicz & Brown (2009) examine the track record of different types of institution in supporting elearning innovation and achieving engagement by a critical mass, and find the two achievements tend to be supported by different types of institutional culture. Another author describes the dynamics of institutional change around elearning based on a series of discussions about elearning diffusion with institutional representatives from across the globe. The author notes that ‘in some institutions elearning was an accepted part of everyday activity, while in others it struggled to gain traction’ (Nichols 2008, p598). There were common factors in institutions that had successfully engaged with elearning across teaching and learning functions, i.e. elearning was approached proactively, was scalable, and self- perpetuating even if not all staff were currently making use of it. There was a sense of flow for elearning, and more confidence in future plans. Unless this sense of ‘business as usual’ is achieved, it is likely that elearning will remain the focus of enthusiasts.

Uys (2007) is another author who describes ideal conditions for elearning to flourish. He proposes the LASO (Leadership, Academic and Student Ownership and Readiness) model to ensure enterprise-wide technological transformation through a strategically developed framework, based on a clear and unified vision and a central educational rationale. LASO emphasizes the need for ‘integrated and orchestrated top-down, bottom-up and inside-out strategies’. Sustainability requires the model to be complemented by a ‘distributed implementation and support approach that advocates true partnerships between academic and support staff' thus providing the capacity for students or staff to initiate and participate in the technological transformation of an institution.

While many authors propose a formula for success, there are few practical examples where all factors are lined up and evidence shows that success has been achieved at a uniform level. It is more common for published articles on the topic to present ideas and works in progress than retrospective reports with evidence of successful diffusion and sustainable innovation. For example, Wiles & Littlejohn (2003) outline the progress of a national Supporting Sustainable eLearning Forum, funded by the UK Learning and Teaching Support Network Generic Centre. The aim of the forum was to move elearning from project-based innovation to embedded practice, and address questions around the scalable nature of elearning. Assimilated views of a wide range of support staff are presented, including ideas on how to devise strategies to support lecturers in the design, development and implementation of online courses; disseminate good practice in sustainable approaches to elearning; and contribute to the ongoing debate in the sharing and reuse of elearning resources. At the time of writing however, this was presented in the form of more great ideas with little evidence to show the outcomes of implementation.

Common challenges

Cox (2008) presents research to highlight common problems and contentions around elearning innovation. She quotes Salmon (2005) on two stages that elearning has gone through as, a) a new way of doing something familiar, and b) doing things that were not previously possible. The second stage is complex, requiring change at both practice and institutional levels, and a solution to the problem of fostering institutional learning about thousands of isolated examples of innovation where no support for systematic change is in place. To address this, she proposes identifying and promoting excellent sustainable, transferable practice and models of change.

Cox's study tests the first four of seven stages of the soft systems methodology described by Checkland (1990 and 2006a & b, cited in Cox 2008), and works with a definition of innovation derived from interview data, i.e:

> Innovation can be defined as a new and useful way of solving existing educational problems, for example, improving student understanding of content. The innovation does not have to be a new tool it could be changing the way an existing tool is used. Importantly any innovation needs to be understood in terms of its context, (Cox 2008, p204).

After an initial data collection phase, Cox aggregated a root definition in the following statement:

> Despite a lack of institutional support and encouragement lecturers find the time to innovate using educational technology in order to enhance their students learning experience as well as their teaching practice. However there is a concern here about who owns the innovation which needs to be investigated further, (Cox 2008, p205).

The next stage in her research was to take these definitions to the people interviewed and find strategies to address the challenging aspects of elearning innovation they had experienced.

Breslin et al (2007) identify many of the same issues as Cox (2008) and others seeking to integrate and sustain elearning systems and practices. Broadly, the issues are pedagogical, cultural and technological. A key point is that senior managers need to reflect on a range of related issues at a departmental or institutional level prior to implementation of new elearning systems. However, experience elsewhere shows that, although such reflection may prepare for many eventualities, there are almost always unexpected outcomes that require the flexible and agile organization identified above by Demirkan et al (2010) to generate an appropriate, timely response. It is unfortunate that these two adjectives – agile and flexible - are not commonly used to describe the organizational structure or processes for responding to innovations in universities.

Reuse of student-generated resources, which are added to a digital repository following review and addition of meta-data by specialist staff, is an example of pedagogical innovation cited by Breslin et al (2007). While this is becoming an increasingly popular concept among elearning enthusiasts, it seriously challenges tradition, and even professional identify for later adopters. Putting these cultural challenges aside for now, a question that remains unanswered is how the proof of concept stage for innovations is managed to ensure elearning systems are the best they can be in terms of educational potential and ease of use by different target groups. Breslin et al (2007) note that proof of concept was achieved, and designs refined through ongoing evaluation involving staff, students and objective data, which suggests good process but would benefit from fuller description. However, the kind of 'special attention' afforded by project resources is not present in normal circumstances, so the fitness for purpose of most elearning tools may be less well refined than it was in the cases involved in the study. Other success factors that receive less attention without the boost of institutional or national funding include strong project management to overcome cross-disciplinary and cross-functional differences. Pedagogical integration is identified as the most problematic issue, and could be expected to present significant barriers to wider use where dedicated support is not available. Another major question unanswered by Breslin et al (2007) as well as other published works, is what happens after the (often substantial) project funding runs out? Support from central university services is proposed, and a business case anticipated, but not actually presented. The authors also note that usability issues would need to be addressed for wider use to become feasible. Integration with enterprise systems has been achieved, although any changes such as new versions or upgrades would need to be addressed. What is not clear is where the mandate or resources to address these and other significant issues will come from.

Dede (2003) reinforces the point about the positive effects of dedicated resources on the success of elearning projects. He describes an initiative where investment in digital infrastructure was a key enabler of general improvement in the educational and professional development prospects in an American school district. In a study of ways the initiative can be scaled up, the author also identifies key questions that need to be answered to claim general applicability. Two significant points are that common purpose and shared vision brought various stakeholders together to solve a practical problem, so barriers to understanding, perceived relevance or the project gaining traction were likely to be absent. The other point is that a high profile researcher with external funding was instrumental in leading the initiative. This created an ideal set of circumstances that are unlikely to exist in institutions pursuing local elearning initiatives, however great the available technology resources are.

Dede (2003) also notes how organizational 'climate' and 'politics' influence progress, and that momentum was lost when school board members changed and a new agenda required refocusing of objectives. Stability and continuity were thus identified as additional success factors. A key strength of the initiative described was that data driven decision-making became instrumental in achieving the goals of improved student learning outcomes and increased organizational effectiveness. However, further research was needed to identify the types of data that would provide reliable evidence to support scalable, sustainable strategies for improvement for practitioners and policymakers. Further research is also needed to identify the conditions that contributed to success with generalizing improvements to other districts. So while this is an interesting successful case, it offers insufficient evidence to support general application, and corroborating evidence from further cases is required.

It's business – but not as usual

In a study of an initiative to embed blended learning in a university's teaching culture, Davis & Fill (2007) also endorse the benefits of the 'special attention' factor of project funding and dedicated staff. They describe the challenges that results when ' champions' retire or move on, and are replaced by staff with less knowledge or enthusiasm for the initiative. Faced with many demands on their time and not fully briefed about why and how particular approaches have been adopted, incoming staff may drop or reduce elearning components. They may be unable to defend the approach to colleagues or students. For those who continue on, there may be issues with maintaining and updating digital resources, especially if the information technology infrastructure changes, or the development and technical support initially provided through project resources is no longer available.

Those who subscribe to the promise of the 'learning object economy' promoted by authors such as Duncan (2004) and Campbell (2003), might respond to concerns about continuity by advocating reuse and repurposing of digital learning resources created by others and made available via centrally managed repositories. However, Davis and Fill (2007) noted that this approach to elearning was far from mature in the UK higher education sector, and in their experience, did not address the real needs of teachers for simple ways to adapt resources created by others without support from technical specialists. Gunn et al (2005) present a case study to illustrate the point, which Johnson (2003) endorses in a paper reporting the outcome of a meeting of thought leaders and practitioners from North America and Australia to discuss the state of play with reusable learning objects. In the latter case, a group came together to identify the systemic challenges inhibiting the realization of a functional economy in learning objects. The purpose was to explore the components of such an economy, and to identify obstacles impeding a reality where learning objects are created and shared, not only within sectors, but also across education, government, business, and national borders. The following quote sums up the discussion.

> No one at the meeting described the current level of activity as pervasive. Discussions over the two days focused rather on how to make the effort reach a tipping point… The issues with the

> learning object economy are content, content, and content. Unless we create an economy of content in which individuals and organizations can acquire, adapt, and repurpose content, the industry won't be successful, Johnson (2003, p7).

With hindsight, it is fair to conclude that the potential of the learning object economy has faded from view because its champions did not prioritize this pragmatic approach, and therefore, failed to reach a tipping point.

Fostering sustainable change

It is clear that sustainable change is a very different proposition to the special attention and resource richness of a funded project environment, and there is valuable experience within the sector to show how it can be achieved. However, it is also evident that this experience is not currently reflected in the policies and practices of funding bodies or recipient institutions. This mismatch is reasonably widely acknowledged, and there are cases that show how it can be addressed. For example, JISC, the UK-based sponsor of a Digital Libraries initiative aimed to ensure that changes made as a result of the project were embedded in the culture of participant institutions by requiring projects to continue for a further 2 years after 3 years of funding. The paper by Davis & Fill (2007) cited in the previous section was written during the two-year extension phase, and it would be interesting to revisit to see how it has survived five years on. The experience of the project revealed a number of factors that were considered critical to success in embedding the changes that the project funded. Active involvement of senior management is one such factor. While it may be easy to secure the letter of support that funding bodies require from senior management to indicate institutional commitment to projects, this often means little more than agreement to allow the project to go ahead without payment of overhead charges. As Lefoe & Parrish (2008) note in their report on an educational leadership capacity building initiative, senior managers need to be more actively and proactively engaged than this to make a difference. However, further challenges arise when the competing priorities and perspectives of senior managers come into the picture.

Challenges also arise from the recommended scale of change. The approach taken by Davis & Fill (2007) involved a complete curriculum review rather than changing a single module within a programme. The review supported identification of suitable places to include the elearning innovation that was the focus for the project. Selection was determined by the ability to serve specified learning outcomes and availability of suitable teaching staff as well as a range of other contextual factors. The challenge of bringing staff from an entire school or department on board is obviously greater, but so are the resulting benefits if the approach succeeds.

Funding is another critical success factor. Davis & Fill (2007) say their project would not have happened without external support. Although staff may be ready to change, they are not supported to take the risks involved in transformation. Support at the point of need is important, yet most universities offer support for elearning as a standardized central service. The limits on what is supported through this type of arrangement combined with the reluctance of central units to expand services and take on new systems is problematic. Staff need immediate support to allow them to continue their work uninterrupted. Many benefits accrue from funded projects, and a new service model that accommodates this type of innovative work is therefore required.

Collaboration is important for both obvious and unexpected reasons. In a collaborative project, it is reasonable to expect development effort to be shared and resources to be reused. Davis and Fill (2007) note that this happened to some extent, but that some benefits of collaboration were more subtle than anticipated, i.e. when working with staff from different departments across the institution helped project team members to gain confidence to deal with challenging times through a common sense of purpose. The authors also report on aspects of the project that didn't work so well, and these roughly reflect the absence of the various factors noted by different researchers as critical to success.

A holistic model for change

While describing a holistic approach to sustainable change, Buchan (2010) notes that only general references to the limitations of institutional support appear in the elearning literature, and explains this as a possible result of the historical separation of management and support from decision-making and use of ICTs. She introduces the concept of panarchy as a holistic approach to project management that offers a broad institutional perspective, while also centralizing the role of the individual. She defines panarchy as:

> …a systems analysis tool for describing and understanding the dynamics and complex inter - relationships of multi-scale institutional projects and the influences of a variety of factors on the learning environment, and on the potential success of elearning initiatives (Buchan 2010, p55).

Panarchy is presented as one of five heuristics in a social-ecological systems approach, which the author uses as the basis to develop a tool for para-analysis. The ‘para’ element of the analysis involves looking beyond the normal organizational perspective on project management to assess the potential impact of projects as well as physical and financial criteria to support decision- making around educational technology investment and support. The process is described in the context of an institutional case study, and involves mapping events and creating a visual representation of a system over time and space.

Four broad guidelines to sustain elearning initiatives include:

- Sustainable funding and IT services models
- A centralized project based approach to educational technology implementation
- A multi-stakeholder approach to managing the implementation of elearning
- Mainstreaming support after the project phase.

Buchan (2010, p73) concludes that this model also supports the decision that some technologies have to remain on the 'virtual horizon' until they can be properly resourced and implemented, and users can learn to use them effectively. There is, however, no description of the decision-making process or who would need to be involved.

The leadership challenge

All articles featured in the literature review for the current study either explicitly or implicitly point to the agency of strong and informed leadership for elearning innovations to become transformational, both across the higher education sector and within its institutions. While acknowledging that leadership and management are very different roles, the reality is that most universities are hierarchies where power and decision-making reside at the top level. It is therefore reasonable to assume that senior managers have a key role in decisions around elearning. In this context, the findings of a UK study commissioned by JISC (Duke, Jordan & Powell, 2008) give cause for concern. The study found that managers who combine a deep understanding of technology with senior management experience remain uncommon in the sector. The situation where management teams rely on collaboration between individuals with complementary skills to provide insight into the actual and potential contribution of technology to the strategic aims of the organization sounds fine on paper. However, in practice, these groups rarely include, or are influenced by front line teachers, despite them being the ones most deeply affected by decisions about technology, and having first hand experience for the organization to learn from. Gibbs & Gosper's (2006) article on the 'upside-down world of elearning' highlights the need for their voices to be heard and influence brought to bear. Otherwise, a worst possible scenario is that elearning will (continue to) be dominated by politics, power and the unrepresentative perspectives of people with limited experience of the workable nature of the elearning environments they are responsible for creating.

To paraphrase Gibbs & Gosper (2006, p51-52), unless educators play a more prominent role in the design of elearning systems and tools in the future, the sector will continue having to cope with the narrow view of education and pedagogically weak designs that are reflected by the capabilities of current systems. Technologies need to be able to accommodate the philosophical underpinnings, as well as the very broad range of activities that characterize teaching and learning environments. The authors equate the experience of using the currently common LMS as 'attempting to teach in a straightjacket', and quote an earlier study where the 'pedagogical awkwardness' of commercial systems led the author to develop his own simple system (Gibbs & Gosper 2006, p47). While the original statement was made some time ago (1999) many practitioners would relate to it today. Institutions should ignore the warning at their peril. Many academics are perfectly capable of pursuing independent courses of action, and in doing so, undermine the institutional objective to achieve standardization through the provision of secure and centrally supported enterprise elearning systems. This risk will exist as long as enterprise systems stifle innovation, as Kuriloff (2001) suggests they do.

Since Gibbs & Gosper’s article was published in 2006, an explosion of free software and social networking tools has increased the range of opportunities for teachers, and with it, the risks to institutions, which can neither stop nor control the tide of elearning innovation. To 'put the right side up', effective communication between software developers and educators is one necessary step, which they believe professional development for all parties may facilitate. In a few universities, people in these roles are co-located in an attempt to raise mutual awareness and increase collaboration, though this model is rare beyond specialist elearning units. Learning design is considered a key role for the future, as it can mediate between the technology and the pedagogy of different disciplines. However, until educators can articulate their teaching and learning needs more clearly, and software developers broaden their understanding of elearning environments and processes, the transformative potential of technology is unlikely to be fully realized. A major challenge is developing the strong and informed leadership capabilities that can steer institutions towards achievement of these objectives.

Working within the system

While innovation and user choice around elearning is definitely to be encouraged, there are clear benefits to framing these opportunities within existing systems. Gosper et al (2007) report on a project involving software selection in the context of curriculum redesign for a university program. The aims were common to those of many initiatives, i.e. to improve learning outcomes, and to increase flexibility of access and approaches to teaching and learning through the use of a variety of software packages and digital resources. It was important to ensure the solutions adopted were manageable within the existing infrastructure of the department and the university so support and maintenance issues did not become unmanageable. The selection process worked out for this case study led to the development of three instruments, which now offer a generally applicable CICTO (curriculum, ICT and organization) framework for selection and integration of software solutions. Key points to consider on the pedagogy dimension include support for an appropriate instructional methodology, integration, interaction, efficiency, effectiveness, value added and feasibility. The technical dimension focuses on process management, assessment, content creation and management, user management, usability and growth potential. Organizational factors are administration and interoperability, financial and asset management, policy compliance, support requirements, workload implications and risk management. These three instruments offer comprehensive support for faculty and academic support staff in selecting elearning tools and systems. They require discussion with technical and development staff, so may serve the additional purpose of raising mutual awareness among the different parties involved. Because they define key decision points that guide user choice, they can also be used as sustainability criteria for developers of elearning systems and tools, to ensure they would pass the selection test in institutions where similar processes may be in place. While the principle of working within the system could be interpreted as being limited by what it already offers, the instruments and processes devised by Gosper et al (2007) actually offer development potential and opportunities for organizational learning, which is a subtle but significant difference.

The future of elearning

Like all educational innovations, the future of elearning has frequently been questioned and remains contested in some quarters. At a time when major investment in online or e-universities was failing, Cronje (2006) rightly asked ‘who killed elearning?’ This marked the end of a period of intense, and with hindsight, totally unrealistic speculation about the potential profits from online education. Such aspirations are a common response to the introduction of any new technology. Early adopters and entrepreneurs rush in to explore the potential. When the period of speculation ends, practitioners with more realitically focused aims can explore the real educational value of various approaches and areas of application of elearning (or whatever educational technology is called). However, it is easy to see how senior management perceptions of the potential of elearning will be shaped by early experience, and endorsed by the limited success rate for funded projects that receive no support after an initial research and development phase.
Cronje (2006) points to misalignment of objectives and needs, contending that return on investment was the over-riding aim, when learning design, management and learning needs should have been equal or higher priorities. He also notes that target markets must be understood, and demand realistically forecast, and uses Khan's (2005) framework for elearning, which focuses on pedagogical, technical, interface design, evaluation, management and support, and ethical and institutional issues to elaborate the point.

When speculation dies down and more realistic expectations come into play, the management tendency to ignore, or even oppose elearning becomes problematic (Cronje 2006, p4). Failed expectations are one common cause of this, and limited understanding a driver. Coherent and concurrent elearning and change management strategies are required, although these can hinder or help, depending on how they are developed and implemented. The common practice of developing strategy at the centre without sufficiently broad consultation brings the problems of low practitioner involvement (Gibbs & Gosper 2006) and limited management knowledge (Duke, Jordan & Powell 2008) to mind. Further reference to McGraw (2001) highlights how poorly informed many approaches to the challenge of sustainable elearning are, and how easily management led strategies can overlook critical elements. In McGraw's paper, the omission is any significant focus on learning needs. For Broadbent (2001, cited in Cronje, 2006) the missing element is logic to a case that cites examples of failed technologies to justify the likely success of the latest innovation (the internet).

Cronje suggests taking the 'e' out of elearning, and returning to the core principles of learning'. For this, he proposes a blend of two approaches, i.e. the ADDIE model of instructional design with the balanced scorecard as a business model. He calls the result the learning scorecard; an integrated model for planning learning interventions that will be aligned with business objectives. However, the strength of his case, which is speculative rather than evidence based, is challenged, when he contradicts his own argument with this quote:

> A successful project is just 20% technique and 80% tactics… no matter how much we try to analyze factors that lead to successful implementation or sustained use of technology in education... it always comes down to human aspects that are simply impossible to quantify Romiszowski (2004, p24).

Cronje (2006, p6) ends with a comment that no one mourns the 'death' of elearning, and as far as the RoI driven movement is concerned this is probably true. For the educational community however, this 'death' marks the beginning of an era of opportunity to explore and exploit real educational potential without the shadow of profit motives and speculation distorting expectations, but with the legacy of failed expectations to overcome.

The problem with innovation

To conclude this overview of key concepts from the literature describing attempts to manage and sustain elearning innovations in universities, it is useful to follow Cronje's lead out of the discourse of education and into the business environment where innovation has been an integral feature for many years. In their seminal work *A Passion for Excellence*, Peters & Austin (1985) note that innovation has always been an uncertain and messy affair. Rather than attempting to control it, they propose designing organizations that take account, and even take advantage of the unpredictable and 'sloppy' nature of the process. Most organizations pursue tidier plans and better-organized teams to 'beat the sloppiness' out of the process, regardless of the fact that this approach has never proved successful in either business or elearning. A better approach would be for managers to learn to create organizations that can respond to, and support innovations. Peters & Austin (1985 p119-120) examine common myths about innovation that need to be dispelled for this to happen. While these were written in a different context, they apply equally to elearning, i.e:

- Substantial strategic / technological planning greatly increases the odds of a 'no surprises' outcome
- Complete technical specs and a thoroughly researched market plan are invariant first steps to success
- Time for reflection and thought built into the development process are essential to creative results
- Big teams are necessary to blitz a project rapidly, especially a complex one
- Customers only tell you about yesterday's needs

A quote that is frequently echoed and worth remembering is that:

> The initial use and vision for a new product or service is virtually never the one that is of the greatest importance commercially (Peters & Austin 1985, p123)

Innovations require very different types of organizational structure and process to that commonly found in universities. Returning to the problem of how funded elearning projects, as instances of innovation, can be transformed into sustainable products, there are some clear implications, but with apparently limited ability for institutions to act on them. To use an analogy from the business world, if projects were seen as the research and development phase of new products, which is essentially what they are, then sales, marketing and technical experts would step in to take them to the next level once proof of concept had been achieved (Gunn 2010, p98). Instead, when funding runs out, if the research and development team has not managed to devise a business model for a sustainable future, then valuable creative work and experience is left to founder.

Case studies and conclusions

This paper has outlined the first stage of a study of the 'state of the art' at the end of the first decade of the 21st century for ways to address the challenge of sustaining elearning innovations. Common problems with attempts to manage the innovation process are identified. One problem is a lack of knowledge among senior managers and decision-makers of what is actually involved in promoting the transformational change that elearning represents. Most of the literature cites management support as critical to success, so the problem is significant. Another challenge is the lack of mutual understanding among different players, i.e. technical staff and software developers, institutional leaders and managers, and teachers and learning support staff. A major barrier to progress is the failure of institutions to learn from the experience of their lead practitioners, or to respond to the needs of valuable educational innovations that exist outside the enterprise system suite of elearning tools. Where these innovations start as funded projects, the lack of ongoing funding and support, or ways to operationalize project outcomes results in low return on investment in both financial and knowledge building terms.

A range of proposed innovation management processes has been identified in a literature review. Analysis of a series of case studies is now in progress to see how these align with practitioner experience. Preliminary results show than initiatives that make a successful transition from funded start up to sustainable product are few, and typically involve exceptionally skilled leaders. Many of the attributes described by authors cited in this paper are present, i.e. adaptability, usability, fit for purpose and a sustainable business model. The most promising current approach combines open source and commercially hosted service, though some systems are purely open source, and a few purely commercial. While all the cases included in the study began as funded projects in some sense, the culture of the institution played a major role in subsequent development. There is, however, an emergent trend for collaboration across institutions that helps to transcend the limitations that arise from the local context of a single institution. Attempts to limit and control access to technical systems are thus being overcome.

The literature review provides the basis to draft guidelines to support sustainability prospects for innovations that prove to be educationally beneficial, technically feasible and practically possible. Development of the guidelines is progressing, using a collection of case studies of successful, stalled and struggling innovations to test usefulness in a range of practical situations. The higher education sectors and institutions in many countries have supported a project-based approach to elearning innovation for the last half a century. Many reports claim the model is flawed because inadequate provision is made for sustaining initiatives after funding has run out. Yet many excellent developments have resulted from the funded project model, and as yet, no viable alternative has emerged. The proposition emerging from the research described in this paper is that it is not the model that is flawed, but the institutional structures and responses that must change to accommodate successful outcomes.

From funded project to sustainable product: elearning innovations in transition

Dr Cathy Gunn
The University of Auckland

Associate Professor Philip Uys
Charles Sturt University

Abstract and Symposium Plan

The transition from funded project to sustainable elearning innovation has been problematic for many years. Most elearning innovations rely on seed funding for a research and development phase that is risky and resource intensive. Once proof of concept is achieved, different skills are needed for dissemination, integration and professional development, and a number of other factors are critical to long-term success, i.e. strong leadership, supportive institutional culture, senior management support, effective professional development and integration with existing technology systems.

In the current tertiary context, there is unresolved tension between the need to experiment with new educational concepts and tools, and the provision of standard, centralized and secure elearning environments. Valuable knowledge is lost when project experiences are not analyzed to inform parallel or future developments. This applies equally to small-scale, developments and broad concepts such as learning objects and open educational resources.

The discussion in this interactive symposium will begin with a working definition of ‘sustainable’ and a brief presentation of the strategies and success ratings from 22 Australasian case studies of funded projects that have achieved varying degrees of sustainability. Delegates will be invited to share their opinions and experience, and to debate the findings from an ACODE sponsored study that concludes:

- The concept of sustainability is problematic in a context of shared, adaptable and transitory ‘products’;
- Confidence in open source systems is limited, as leadership and resources are still required;
- Committed and capable individuals remain the single most important success factor for sustainable innovations;
- Institutional structures and process are at odds with the management and governance needs of innovations, resulting in some great elearning products with owners that don’t care;
- Project funding for two or three years is enough to produce a good working prototype but not a complete and self-sustaining product.

These findings challenge the relevance and expectations of the funded project model. With participants' consent, the outcomes of the discussion will be disseminated with case study findings.

Teachers' Beliefs and Use of ICTs in Malaysian Smart Schools: a case study

Seri Rahayu Hamid
School of Education
University of Queensland

This preliminary study investigated Malaysian secondary *Smart School* teachers' beliefs about ICTs and how they are used in their classrooms. Using a case study design, data were collected from focus group interviews with 31 Science, Mathematics and English teachers from three Malaysian secondary schools, and from journals of three students. Results showed that although these teachers held positive beliefs about ICTs in education, these beliefs were not fully translated into their classroom practices. Most of them believed that ICT was just a tool to use in teaching and learning, particularly if it eased knowledge dissemination, and helped students to understand the content. The analysis revealed early career teachers were using ICTs in more varied ways than the more experienced teachers. Many of these early career teachers communicated with their students through blogs and online groups; practices that were rare among the more experienced teachers.

Keywords: ICTs, teacher beliefs, teacher practices

Introduction

Despite the increasing availability of infrastructure and equipment, teachers' use of ICTs, as reported in numerous recent studies, has been limited (Eteokleous, 2008; Lim & Chai; 2008; Nichol & Watson, 2003; Reynolds, Treharne, & Tripp, 2003; Sandholtz & Reilly, 2004; Smeets, 2005). In some studies of the extent of successful ICT use in classrooms, teachers were not fully using ICT in teaching and learning (Eteokleous, 2008; Nichol & Watson, 2003; Reynolds, et al., 2003; Sandholtz & Reilly, 2004), even when their schools were fully equipped with technology (ChanLin, Hong, Horng, Chang, & Chu, 2006; Zhao, Pugh, Sheldon, & Byers, 2002).

Teachers have often cited the inadequacy of ICT equipment and resources (Bauer & Kenton, 2005; ChanLin et al., 2006; Zhao et al., 2002), and the lack of adequate knowledge and skills (Brummelhuis & Kuiper, 2008; ChanLin et al., 2006; Eteokleous, 2008; Yang & Huang, 2008) as significant factors contributing to their limited use of ICTs in the classroom. However, Hokanson and Hooper (2004) suggested that the real challenges to teachers' uses of ICTs are pedagogical, curricular, and methodological. And to advance into higher levels of ICTs integration in teaching and learning, changes in teachers' beliefs are required (Hixon & Buckenmeyer, 2009).

Previous research has indicated that teachers' beliefs about ICT play a significant role in determining teachers' ICTs use (Ertmer, 2005; Ravitz, Becker, & Wong, 2000;Windschitl & Sahl, 2002), affecting their intentions to use ICTs in the classroom (Goos, Galbraith, Renshaw, & Geiger, 2003; Jimoyiannis and Komis, 2007), and the ways teachers choose to use ICTs in the classroom (Ruthven, Hennessy & Brindley, 2004). This study aims to build on this knowledge by examining teachers' beliefs and how they affect ICTs use in the classroom in the Malaysian context. The following research questions guided the study:

1. How are ICTs being used for teaching and learning of Science, Mathematics and English in the Malaysian secondary *Smart Schools*?
2. How do teachers' beliefs affect their use of ICTs for teaching and learning of Science, Mathematics and English in the Malaysian secondary *Smart Schools*?

Method

Participants

This study recruited teachers from three subject areas as participants. They were 31 teachers of Science, Mathematics, and English from three secondary *Smart Schools* in Kuala Lumpur and Putrajaya, Malaysia. Two Form Five students and one Form Four student were recruited (one from each school). These 31 teachers were divided into nine focus groups. Each school had a separate focus group for English teachers, Science teachers, and Mathematics teachers respectively. The number of teachers per group varied from three to five, depending on the availability of teachers at interview time. Only three teachers were male, while the rest were female. Their teaching experience varied from 4 months to 25 years. The majority of the participants held a bachelor's degree. Three held a master's degree and one held a diploma in education.

Data sources

This study adopted a case-study approach to explore the interaction between Malaysian secondary *Smart School* teachers' beliefs about ICTs and how ICTs are used in their classroom. It involved the use of focus groups and document reviews as main sources of data. Focus groups were used to understand the underlying beliefs that influenced those teachers' uses of ICTs for teaching and learning in specific subjects. A focus group protocol was developed and used to guide the discussions, and all focus groups were recorded and transcribed.

To provide an alternative perspective of how ICTs were used on a daily basis in the classrooms three students' daily journals were also used as a data source. These journals provided daily snapshots of how ICTs were used for the teaching and learning of Science, Mathematics and English in these schools. The students were provided with a bound set of journal entries templates which served as a guide to structure their responses.

Analysis

The data were first coded according to their sources and the research questions. Data analysis consisted of within-case analysis and cross-case analysis (Merriam, 2009). The within-case analysis took place first. For each school, the associated focus group discussions and student daily journal entries were analyzed to develop a rich description of the case. In order to understand the different uses of ICT observed in this study, the classifying scheme by Means (1994) was adopted. Means classified technologies according to how they are used for teaching and learning namely Tutorial, Exploratory, Tool, and Communication. The categories were applied to highlight differences in the instructional purposes of various technology applications. Following the within-case analysis, the cross-case analysis was carried out, exploring the similarities and differences among the three schools with regards to the research questions.

Findings

A significant finding of the preliminary study was that the teachers in the study generally held positive beliefs about the use of ICTs in education. Despite that, their focus on preparing their students for national examinations resulted in them viewing ICTs as tools that could help speed up or simplify the delivery of their teaching content. This led to the significant use of ICTs as presentation tools. However, further analysis showed that the early career teachers of the three subjects used ICTs in much more varied ways compared to their more experienced colleagues. These younger teachers used blogs, e-mails, online groups, online teaching, YouTube, Skype and movies, while the more experienced teachers preferred to employ the traditional, lecture-style teaching and learning method by utilizing mainly PowerPoint presentations and the teaching courseware.

Discussion

The findings from the preliminary study suggest that the teachers' different beliefs and practices regarding the use of ICTs in the teaching and learning of their subject should be further investigated. This may provide a deeper understanding about how teachers can share and learn from each others' differences to promote greater uses of ICTs for teaching and learning. These findings led to a more in-depth study which aims to investigate how early career and more experienced teachers can co-mentor each other to influence beliefs, ICTs practices and pedagogical practices.

Sherah Kurnia
Department of Information Systems, University of Melbourne, Australia

Online social networking (OSN) activities are becoming more prevalent in higher education. The phenomenon can be observed in many higher learning institutions around the world. There are many ways of appropriating OSN for teaching and learning. OSN enables lecturers and students to publish and share knowledge quickly and easily. However there are also several challenges which include the limited skills in using social technologies among lecturers and students. This paper discusses the findings from two case studies conducted using an exploratory approach employing semi-structured interviews to gather lecturers' perspectives on their appropriation and use of OSN. The findings demonstrate a range of approaches used as well as the benefits and challenges faced by the lecturers in appropriating social technologies for teaching and learning. The finding can be used as a guide for other lecturers and educational designers to improve the use of OSN activities in higher education.

Keywords: Online Social Networking, Appropriating, Teaching and Learning, Higher Education.

1.0 Introduction

Online social networking (OSN) activities are becoming more prevalent in higher education around the world (Mason & Rennie, 2008; Hughes, 2009; Kear et al, 2010). OSN is defined as a range of activities enabled by social technologies and operationalised by a group of people (Hamid et al, 2009). In the context of this paper, the social technologies of interest include blogs, microblogs, wikis, social networking sites, video sharing sites and online discussion boards or forums.

The driving factors for adoption of OSN include the increasingly ubiquitous access, ease of use, functionality, and flexibility of social technologies (Brown, 2010; Schroeder, Minocha & Schneider, 2010). It has been argued that, in the context of higher education, social technologies can support social constructivist approaches to learning; they have the potential to extend students' construction of knowledge and promote student interaction (Ferdig, 2007; Schroeder et al, 2010; McLoughlin & Lee, 2008). A further benefit of social technologies provided on the Web is that they are often free or require marginal investment, removing a potential barrier to adoption (Brown, 2010).

While research into the use of OSN in higher education is gaining more momentum, there remains a dearth of research that aims to understand the different ways lecturers are appropriating these social technologies for educational purposes. Anecdotal evidence is rather inconclusive with regards to the benefits and challenges faced by the lecturers and students when OSN technologies are introduced for classroom activities. This research aims to conduct an in-depth analysis of two case studies examining how two different lecturers in two Malaysian universities have appropriated social technologies for educational purposes. The research also aims to identify the benefits and challenges the lecturers encountered in their use of OSN for their teaching and learning. The two case studies provide preliminary insights into the appropriation of social technologies, and the benefits and challenges of OSN use for higher education. This paper is expected to contribute and enrich current understanding of how lecturers appropriate OSN and the actual benefits, challenges as well as the outcomes as experienced by them.

In the next section we provide more detail about the concept of appropriation of OSN for education, and discuss the benefits and challenges of OSN in higher education as synthesized from the extant literature. This will be followed by an overview of the methodology and data analysis techniques used for this paper and a discussion of the findings from the two case studies. Lastly, the contributions, limitations and future research will be discussed.

2.0 Literature Review

Conceptually and practically, OSN enables its users to socialise and create networks or communities online. In the higher education sector, publicly available social technologies for OSN are being appropriated for educational activities. That is, technologies originally designed for social, or non-educational, purposes are being used and repurposed to support pedagogical approaches in higher education (Hemmi, Bayne & Land, 2009). There are several views on what appropriation means in the context of using new technologies. Degele (1997) argued that the concept of appropriation comes from creativity, with users creating new ways of using tools, distinct from what the developers and managers originally designed and developed the software or application for. Orlikowski (2000) viewed appropriation as 'technologies-in-practice' in the context of IT use in organisations. Waycott (2004) examined appropriation as the integration of new tools into user's activities, while Hemmi et al (2009) used the term appropriation to describe the use of social technologies in the educational realm. According to Jones and Twidale (2005), there are two types of appropriation: (1) serendipitous appropriation which includes the uses that arise out of spontaneous creativity, and (2) goal-oriented appropriation, where a user finds a technology that can help him or her satisfy a need or aid in attaining a specific, defined goal. Additionally, Fill et al (2006) argued that pedagogically appropriating certain technologies is part of a teacher's expertise. Hence, academics need to equip themselves with the knowledge and skills to appropriate social technologies for their teaching purposes.

Previous works, especially by Kennedy et al (2009) who studied the general use of information technologies by young students, and Hemmi et al (2009) and Jones et al (2005), who studied the use of social technologies, suggest that the appropriation of social technologies is not an easy and straightforward process. As higher education deals with a new generation of students who are perceived to be familiar with OSN and social technologies, the literature has shown evidence of some efforts made to use these technologies to support educational activities with a certain degree of success. However, the process of appropriation of the social technologies is not well researched and can be considered a big gap in this research space.

Researchers have also argued that the pedagogical and social affordances of OSN should be leveraged for enhancing educational outcomes of students (Lee & McLoughlin, 2008; Tay & Allen, 2011). Tay and Allen (2011) argued that students should be given the choice to use the tools that they feel comfortable and familiar with and that they believe are viable for completing the tasks at hand. In this regard, the social affordances of OSN might not be provided in one particular social technology but rather in the combination of several social technologies. Therefore, lecturers could be advised to avoid specifying social technologies but rather specify the processes for the students to discover what will work for them. However, this approach may not be practical for lecturers teaching large classes. Furthermore, it may be difficult for lecturers to translate the potential of social technologies into actual usage (Bowers et al, 2010). Bowers et al proposed a Web 2.0 learning design underpinned by the Taxonomy of Learning, Teaching and Assessing. They focused on technology as a mediator of interaction and at the same time emphasised the importance of considering the content and pedagogical aspects of the task when designing a Web 2.0 learning activity.

We situate our study within the framework of learning, teaching and assessing as discussed in Bower et al (2010) and also within the context of understanding the pedagogical and social affordances of social technologies described by Lee and McLoughlin (2008) and Tay and Allen (2011). Based on a comprehensive literature review, we identified four categories of OSN educational activities, namely content generating, interacting, sharing, and collaboratively socialising (Hamid et al, 2010). Most social technologies allow users to easily create their own content and also to actively share information, opinions and support across networks of users. Students can write entries in blogs or wikis or record an audio file for a podcast lecture series (Kaplan & Haenlein, 2010; Hemmi et al., 2009; Kane & Fichman, 2009; Ras & Rech, 2009). Generating content can also involve creatively producing multimedia content for posting on file sharing sites such as YouTube (Anderson, 2007; Sandars & Schroter, 2007). Using social technologies, students are easily able to publish their work and ideas in a public space for others to view and download. For example, multimedia files can be shared on file sharing websites such as Flickr, YouTube or Slideshare, and social bookmarking sites allow users to bookmark certain websites or tag keywords for users with similar interests to peruse (Andreas et al, 2010; Murray, 2008; Ras & Rech, 2009). Sharing content and information using social technologies can mean much more than just publishing them online. It may involve further improvement and enrichment to the content and information being shared. For instance, someone else might expand the contents by putting more facts and figures or correcting erroneous data such as on Wikipedia.

Social technologies support interactions among students by allowing them to actively participate in a discussion. They can leave comments on a blog or discussion board and ask for more detailed explanations, adding someone as a friend and initiating communication by leaving a message (Kaplan & Haenlein, 2010; Hemmi et al., 2009; Munoz & Towner, 2009). In addition, interaction can involve responding to others' blog postings, co-writing wiki entries to enrich content on a selected topic, and joining a group on social networking sites (Andreas et al, 2010; Kane & Fichman, 2009). Students can work collaboratively in an online social environment to solve certain issues or problems with their peers, or to organise social events (Andreas et al, 2010, Hemmi et al., 2009; Kane & Fichman, 2009; Munoz & Towner, 2009). By collaboratively socialising also, students can establish and actively communicate with the contacts made online, with the aim of working towards particular outcomes or producing deliverables, in both online and offline modes (Lockyer & Patterson, 2008).

Based on a review of the extant literature we have identified four major benefits of OSN use in higher education, namely improving engagement, enhancing learning motivation, offering personalised course material, and developing collaborative skills (Wheeler et al, 2008; Rifkin et al, 2009). OSN activities have the potential to improve student engagement and increase their participation in classroom, in particular among quieter students. Students can work collaboratively online, without the anxiety of having to raise questions in front of peers in class – or by enabling expression through less traditional media such as video (Wheeler et al, 2008). Quieter students may feel reluctant and hesitant to participate and interact actively in class. However, with the use of online technologies (be it blogs, wikis, Facebook, and etc), the students are more likely to participate online compared to face-to-face interaction as some students may have a personal trait of being shy to speak up in public. Students may also create a sense of belonging and ownership when they are given the freedom to publish their work online (for instance in the personal blog related to the course) or contribute to the class blog. Learning to use social technologies can further boost students' motivation and may, in fact, improve the overall quality of students' work. A study by Rifkin et al (2009) indicates that when students publish their work online for multiple audiences, the external audience motivates them to create original, interesting and engaging work. This in turn can lead to a more positive assessment from the peers and lecturer.

In addition, lecturers have reported that the use of online technologies can encourage online discussion amongst students outside school, beyond the traditional classroom setting (Gray, Chang & Kennedy, 2010). In the case of social networking sites or blogs, when students update their user profiles and personalise their respective pages, they can provide comprehensive information about themselves (e.g., full name, date of birth, address, educational background, hobbies, social, and even political or religious affiliations). The academics who are using such technologies in their classroom will then be able to learn more about the students they teach simply by viewing the students' profiles (Griffith & Liyanage, 2008). In response to this, lecturers can personalise the course material based on the students' profiles (Oradini & Saunders, 2008). Some social technologies such as wikis and to some extent blogs, encourage inquiry-based and collaboration activities among students. This opens room for active participation and can therefore create opportunities for effective learning. Linked with this principle of collaborative production, social technologies enable learners and teachers to share and publish artefacts produced as a result of the learning activity (e.g., course materials such as course syllabus, course notes, assignments, test cases, etc) and invite feedback from peers. By publishing and presenting their work to a wide audience through blogs, wikis, or podcasts, learners benefit from the opportunity to appropriate new ideas, and transform their own understanding through reflection (Dale & Pymm, 2009).

Previous research has also identified challenges associated with using social technologies in higher education. Jones et al (2010) conducted an empirical investigation of OSN use in four universities in the UK involving 76 questionnaire participants and 14 interviews with students. They found five challenges of social software for learning such as the separation of life and studying; originality and copyright issues; sense of information flooded; time constraint, and lecturers are not up-to-date and may not know how to integrate and make use of social software. Their findings confirmed in general the earlier issues highlighted by Kennedy et al (2009) based on their Net Generation research in three Australian universities. In their report, Kennedy et al (2009) listed six policy issues which teaching and learning with technology should address: student learning; diversity, equity and access to technology; curriculum and assessment; academic integrity; staff development and capacity building, and lastly, ICT infrastructure. Despite the benefits and challenges identified, Kennedy et al (2008) also cautioned educators that not all young generation students are attuned to OSN. Therefore, lecturers are advised to be mindful in their appropriation and use of OSN as to cater to the various students' learning preference. The literature discussed above has been used to establish deeper understanding of the topic and to guide the empirical data collection and data analysis for the research reported in this paper.

3.0 Methodology and Data Analysis

This section explains the process we used to collect, code, and analyse the data from two case studies examining the appropriation of OSN in higher education by two lecturers in Malaysia. We chose to use a case study approach because it is appropriate for exploring contemporary phenomena (Yin, 2003) and focuses on understanding the dynamics present in a situation being investigated (Eisenhardt, 1989). Using the case study approach, researchers gather rich depictions of the social context of the studied phenomena, resulting in rich and insightful information (Yin, 1994).

Research Setting

This research took place in two Malaysian universities. There are two main motivations for conducting this research in the localised context of Malaysia. Firstly, the principal researcher, who is Malaysian, has a better understanding of the context. Thus, understanding the culture, social values and language enabled the researcher to be fully engaged with the research context and develop a deeper association with the research participants. Secondly, Malaysian higher education has started to adopt OSN on a wider scale and young Malaysians are very active users of OSN (Zakaria, Watson, & Edwards, 2010). Therefore, the Malaysian context offers a good opportunity to explore the phenomenon investigated in this study.

The two case studies described in this paper are drawn from a larger ongoing study involving interviews with Malaysian and Australian lecturers. For the purpose of this paper, two cases considered revelatory cases were investigated in detail. In the first case, the lecturer applied a systematic and detailed appropriation process that has not been identified or reported in other studies. Further, in this case the lecturer no longer needs to allocate a certain percentage of marks in her assessment to encourage students to interact and participate. This is not typical and suggests that the appropriation of social technologies in this example has been successful. In the second case, the lecturer appropriated four social technologies seamlessly in his teaching. This, again, is an unusual practice: other cases generally only employed one or two social technologies. In both cases studied here, the students were pre-service teachers pursuing education degrees.

Data Collection and Analysis

The data collection involved interviews with two lecturers in two Malaysian public universities in July 2010 and August 2010. Potential participants were identified based on personal contacts and through their university's websites. The final selection of the participants to be involved was then based on their use of social technologies after they responded to an initial invitation. Interviewing was chosen as the data collection method because it provided the researcher with the opportunity to collect rich data that revealed lecturers' perceptions of the benefits and challenges they faced when appropriating OSN in their teaching practices. Bryman and Bell (2007, p. 474) argued that the use of semi-structured interviews offers flexibility where the interviewer "picks up on things said by interviewees" and "the interviewee has a great deal of leeway in how to reply". This approach also allows person-to-person interaction where the researcher is able to alter the line of questioning depending on the answers and discussion. Specifically, the participants were asked about the process they used to identify and appropriate OSN, the advantages they perceived of using OSN for their students and for themselves, and lastly the obstacles they and their students encountered while using OSN. The duration of interviews was between 40 minutes to 1 hour. The interviews were audio taped and transcribed.

The data were analysed manually using thematic analysis (Boyatzis, 1998). All interview transcripts were printed, read multiple times, and notes were recorded in the margins to identify potential themes. These were then collated, reviewed, and examined for connections and redundancies. Over time, the themes were expanded, contrasted and changed. For this current work, our focus is mainly on the appropriation process as well as the benefits and challenges of OSN use from the two lecturers' perspectives. To mitigate potential subjectivity bias and provide triangulation, the data analysis was reviewed by multiple researchers involved in this study.

4.0 Findings and Discussion

Table 1 below summarises the context of both case studies in terms of what and how social technologies were used. Below, we provide a detailed discussion of the findings based on the data analysis. First we discuss how the two lecturers were using social technologies to support OSN activities, then we describe the OSN activities in more detail, followed by a discussion of the processes lecturers followed when appropriating social technologies for educational purposes, and an outline of lecturers' reflections on the benefits and challenges of using OSN in higher education.

Table 1. Summary of OSN activities for the two case studies

Attributes	Case Study 1 (Lecturer A)	Case Study 2 (Lecturer B)
Social Technologies used by the lecturers	Blog and Facebook	Wiki, Twitter, Facebook, SlideShare.net

OSN Activities (used by both lecturers and students)	**Content generating:** lecturer notes, related link and examples. **Sharing:** related questions to test students' understanding and students can share draft assignment for feedback. **Interacting:** students interact and discuss topic assigned**,** give their reflection and for other students' to comment. **Collaboratively socialising:** Facebook used more for small group discussion	**Content generating:** Assignments prepared in Wiki, Slideshare.Net as substitute to LMS in publishing lecture notes **Sharing:** announcement, update and sharing interesting and relevant articles (post the link) using Twitter especially to unplanned updating **Interacting:** Informal interaction in Facebook to motivate and enhance students interaction **Collaborative socialising:** group work through Wiki
Assessment approach used by the lecturers	Assessment for interaction using OSN (in the past, lecturer allocated 5% to encourage and motivate students use of the social technologies. Currently, there is no need to provide such marks due to strong and positive support from the students)	60% of assessment marks for Wiki and it includes face-to-face and online interaction
Methodology used by the lecturers	OSN is used as a supplement to conventional teaching and learning approach.	
Issues faced by the lecturers	Time management Limited skills (students) Limited ICT infrastructure	Time management Limited skills (students) Limited ICT infrastructure

Social Technologies for OSN Activities

In Case Study 1, the lecturer interviewed is a female lecturer, aged more than 45 years old and has experience of teaching for more than 15 years. She holds a senior lecturer post at the Faculty of Education in an anonymous University A. Her passion in teaching supported by the use of technology is evident from her early career where she adopted Web 1.0 tools such as the Yahoo! Group and group email to support her teaching. In this particular study, the lecturer used blog on WordPress and Facebook.

> *"For teaching and learning, mostly I use blog (WordPress). I also use Facebook. However, I am not using Facebook for teaching, just for announcement purposes. It is very much like Twitter, we use it to let the students know what is going on."*

In the second case study, the lecturer interviewed used four social technologies seamlessly. The lecturer is a male, aged between 35 to 45 years old and has been teaching for 10 years. The course he is teaching is a core subject for final year undergraduate students in University B. Similar to the first case study, the students taught in this course are pre-service teachers who will graduate to become qualified secondary school teachers. The decision to use social technologies was influenced by the lecturer's own educational background; he also conducted academic research on the use of Wikis. In addition to the Wiki, the lecturer also used Twitter and Facebook to support communication with the students.

> *"There are four social technologies that I use. First* is *Wiki, second is Facebook and the third one is Twitter. While Facebook is really popular among my students, I used Twitter because it has the ability to send information very fast. Further, I don't have to use proper sentences to type in like in Wiki. Lastly, I uploaded my lecture notes on SlideShare.net. I asked my students to do the same."*

In the context of adopting social technologies, it is observed that the lecturers in both case studies have not resorted to using only one social technology. The use of supporting technologies in addition to the primary tools provides evidence of how social technologies have become arguably prevalent in today's classrooms. In both cases, social technologies are used to complement the traditional face-to-face teaching delivery. This also indicates that conventional teaching and learning is still relevant but made more relevant by introducing newer technologies to provide an enriched learning experience for students.

Online Social Networking Activities

Content generating: As can be seen in Table 1, in both cases social technologies were used for content generating. This included the publishing of lecture notes by the lecturers and sharing of the class resources. Further, the students also used the social technologies to generate content when they wrote up their reflections in blogs or prepared their group assignments in Wikis. In the first case study, students used blogs to write weekly reflections about the concepts they had learned that week. Because students published their reflections of what they had learned each week, the lecturer and students were able to easily chart the students' progress and understanding of the topic. The lecturer mentioned:

> *"I think I can now easily see how my students progress over the semester. I can gauge their understanding of the course by seeing how 'wiser' they have become (in relation to the course) at the end of the semester as compared to when they are in the beginning of the semester. Beyond assessing them in formal examination, at least this way also tells us whether we have achieved or not the learning objectives set early in the semester."*

In the second case study, the lecturer occasionally shared the links he found on the Internet with the students via Twitter instead of putting up the links on the course's LMS. The beauty of Twitter, according to the lecturer, is that it was fast and easy to use. Where necessary, the lecturer also sent notifications to his students if the class had to be postponed due to some unavoidable reasons.

Sharing: The lecturer in the first case study also shared related articles about the topic discussed and some of her past year exam questions she thought the students might benefit from. The lecturer expected that the students would in return use these past year questions to test their understanding of the topics and discuss among themselves for possible answers. Despite doing this, the lecturer acknowledged having no knowledge of whether the students were really using these past exam questions to prepare for their examinations. The lecturer in the second case study shared new contents uploaded to third party sharing websites such as Slideshare.net and later tweeted the information about the uploaded documents to the students via Twitter. The lecturer encouraged students to share the information with their friends who had no access to Twitter.

> *"Typically, every time I found new materials that I think my students would benefit from, I would share the links immediately on my Twitter. Sometimes I also share random thoughts that I have just to challenge my students' analytical skills."*

Interacting: In both case studies, the lecturers used the social technologies, particularly Facebook, to support informal interaction with their students. Similarly, students were encouraged to use the same medium to interact among themselves. In the first case study, besides the reflections made in blogs, the students were commonly seen continuing their reflections and discussions via informal interaction in Facebook. The second lecturer claimed that his students frequently asked him questions pertaining to the course on Facebook. This informal mode of interaction helped the students to tap more of the lecturers' expertise and this was beneficial to not only students who asked the questions but also other students who were just lurking on the class Facebook group. The use of Facebook was critical when it came to the group project. The students were divided into several groups in which they are assigned to develop a multimedia presentation related to the course's topic. The lecturer mentioned the active use of Facebook by the students to support their small group discussions (of 4-5 students per group) and this sometimes led to a face to face meeting among themselves.

Collaboratively socialising: The first lecturer (case study one) used Facebook as the chosen medium to support this OSN activity. She encouraged the students to virtually 'mingle around' with all the registered students in the class Facebook group. She claimed that some students preferred only to keep their socialisation among friends whom they were comfortable with. The lecturer also expected students to extend their socialisation into meaningful learning experiences (i.e., collaboratively socialising in common pursuit of amassing knowledge).

> *"I encouraged my students to collaborate among themselves in completing their group works. I frequently see the students interacting among themselves on Facebook and surprisingly, they are discussing about the assignments I gave them."*

The second lecturer widely adopted a Wiki for supporting collaborative socialisation among his students. The lecturer claimed that the Wiki was an 'e-whiteboard' where students could put up their work. This analogy described the ability of Wiki to hold an amount of students' work in the repository and where other students could edit (add, remove, change) the content easily. The collaborative work supported by the Wiki made co-creation of content easier, and the published final outputs could also be easily shared.

Appropriation Process of Social Technologies for Educational Purposes

In the context of appropriating social technologies for teaching and learning purposes, the lecturer in the first case study described a systematic way of identifying and using social technologies for her class. Interestingly, the appropriation process was strongly influenced by her own research interests in understanding students' learning preferences. The lecturer mentioned four stages involved in her use of the OSN activities. These were (a) pre-implementation, (b) choosing the social technologies, (c) designing and using the social technologies, and (d) assessing the effectiveness.

In pre-implementation, the lecturer made use of Biggs' learning style (Biggs, 2003) to understand students' preferences. Based on the lecturer's own research performed in 2001, the lecturer discovered that most of the students could be categorised as persons who prefer visual information rather than auditory information. She also discovered that the students who were introverts made up a small proportion of students and in comparison, most of the students saw themselves as extroverts. The lecturer conducted a simple SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis to choose the right social technology. Typically, the lecturer compared at least two social technologies side by side. In addition to paper-based SWOT analysis, the lecturer would test-drive the social technologies to assess their usability. This trial-and-error approach had seen the lecturer adopt Friendster, a social networking site, for a short period of time with her students. According to the lecturer the students liked Friendster and used it every day as for socialisation. However, the lecturer chose not to continue to use it because it could not be used to systematically upload content and useful class information.

In designing and using the social technologies, the lecturer looked at four critical considerations of her use of OSN; content, delivery, outcome and service. The lecturer developed the course content for both face-to-face lectures and the virtual interaction via blog based on the syllabus requirements. From the delivery angle, while the main approach was still face-to-face lecture, the use of a WordPress blog for course reflections was given strong emphasis. On the outcome side, the lecturer expected that the students' learning outcome would match the expected learning outcomes designed for the course. This was done through a set of assessments, discussed below. To address the service aspect of her use of OSN, the lecturer committed to posting something related to the course every week. She also ensured that she replied to the students' comments, however minimal (e.g., by saying something as simple as *"I noted your suggestions", "Thanks for your comment"* or more elaborate feedback such as by *"I totally agree with your view. Further, if I may offer an alternative view to that initial thought of yours …."*). The lecturer claimed that the comments would indicate to the students that she actually read and appreciated their replies. The lecturer also added that, if the students sent her a link to visit, she would make an attempt to do so and provide her own views about the materials shared by the students. By doing so, she believed the level of student's motivation would increase and they would be more engaged with the course.

For assessment, the lecturer normally assessed the students' works once they had completed their assignments. While the students could submit their draft answers via their blogs, these preliminary write-ups could not be considered as their finalised job. Hence, only after the due date of submission would the lecturer fully obliged to assess the students' outputs.

The appropriation approach demonstrated by the case study one above fits the goal-oriented appropriation as suggested by Jones and Twidale (2005). On the other hand, the lecturer in case study two arguably used the serendipitous appropriation in which the use of social technologies arose out of spontaneous creativity (Jones & Twidale, 2005). In this case, the lecturer had no clear process or formal preparation for the OSN use. Instead, the implementation just grew 'organically'. Specifically in the second case study, the lecturer spent some time explaining the social technologies he intended to use to complement the face-to-face lectures. The lecturer gave an overview of the technologies, demonstrated how these technologies would be used for the course purposes. He also asked the students to experiment with the social technologies to give them a sense of familiarity with the tools. The lecturer explained:

> *"I will allow the students to play around with the Wiki to get familiar with the tool. For example, in Wiki, I ask groups to introduce members of their group. They put in their profile, names, their area of specialisation, as well as their interest in becoming teachers, why do they want to take my course, sort of personal reflections within the group."*

For the course assessment, the lecturer allocated sixty percent of the course marks on assessment alone. These marks were mostly for the group work project in the Wiki. The levels of interaction among group members in traditional classroom setting and in Wiki were given emphasis. Asked about how the lecturer allocated marks for interaction, the lecturer argued that the quality of work determined the interaction level. He claimed that there was a correlation (while not numerically justified) between a high degree of interaction among students and the quality of students' work.

It is interesting to note that no common method exists either in the literature or found in the field pertaining to the way social technologies are being used for teaching and learning. Despite that, the first case study provides an exemplary case on how lecturers could systematically leverage social technologies for OSN activities.

Lecturers' Reflections on the Benefits and Challenges of Using OSN

The following discussion describes lecturers' reflections about some of the benefits and challenges resulting from their appropriation of social technologies for use in higher education.

Engagement and interaction: In regards to engagement and interaction with students, both lecturers in the two case studies believed they engaged and interacted better with the students particularly those termed as introverts. Both of the lecturers observed that students who were introverts had many good ideas to share with the class. However, their natural dispositions limited them from being vocal like the extroverts. Using social technologies as the platform, this situation could be overcome and the two lecturers noted that introvert students were now more competitive with their peers. This created a synergistic relationship, beneficial for students' academic development. According to the lecturer in the first case study:

> *"For introverts at least they now have a platform to communicate although they become lurkers in the beginning ... but at the end, if they want to start speaking, this will be the first platform."*

Appropriation of social technologies helped the lecturers in both cases to come up with creative and innovative ways of teaching and learning. Using more than one social technology provided variety, offering more options to create an enjoyable learning experience for students. For example, the lecturer in the second case study noted his class had changed into a more 'lively' environment after using social technologies. The students were more open and talkative (in a good way) as a result of their online interaction, having made their revisions and work together in a significant amount of time on Wiki and on other tools especially Facebook. According to the lecturer, this phenomenon was totally opposed to what he had observed in his previous classes that used the traditional lecture-based and the lecturer-centric approach.

Time management: The lecturer in the first case study found the use of OSN was not really time consuming. She even considered the use of OSN as really easy and said it required less work than the traditional mode of teaching. Pedagogically, she claimed that she just 'extended' her previous use of Web 1.0 tools such as group email to the new stream of applications labelled as Web 2.0. The lecturer in the second case study mentioned the ability of the social technologies to make learning go far beyond the realm of the physical classroom. Specifically, the lecturer argued that social technologies extended the classroom experience beyond the classroom hour into what he termed 'virtual time'.

> *"I think it becomes the extended class from my face-to-face meeting with the students. So it extends the class activity beyond the class hour. I cannot be there to monitor all their activities so I use these tools to monitor what they are doing and learning and what's their discussion all about. In short, when my student and I used the social technologies, we are able to have what I can say as the 'virtual time'."*

Challenge of limited skills: The lecturer in the first case study argued that the challenges of using OSN in higher education could be lecturer-specific. This is because she had not faced any major problems in using the social technologies. This observation might be true especially in the case of proactive lecturers who are appropriating and using these technologies without being asked to do so by the faculty.

The second lecturer, however, mentioned some challenges that had affected his students. For instance, he found it challenging to introduce the students to a new tool that was not familiar to them. While the use of Facebook appeared to be second nature to the students, a similar view could not be generalised to the use of Twitter and Wiki. The lecturer claimed that the students were not familiar with these two tools although they had some awareness of the tools. In general, the students had an awkward response when being told of the use of Twitter and Wiki for their classroom support. In order to overcome this situation, the lecturer had to encourage the students to experiment and acquire more skills through frequent use of the tools.

> *"Students are not familiar with the technology. I have to push them to acquire the skill. Generally, they have heard of it, seen it but never participate using it. I think it takes some time for the students to embrace and getting comfortable in using such technology (e.g Twitter) for classroom purposes."*

Challenge of limited access: The lecturer also faced another challenge in the form of students' limited access to the Internet. The class was conducted in the computer lab but beyond that, the students had to access the Internet via the university's campus-wide wireless infrastructure. Additionally, some students did not have the latest range of mobile phones that are capable of running mobile social technologies, particularly for Twitter and Facebook. Some students could not afford to own smart phones although all of them carried mobile phones. To respond to this problem, the lecturer and his students had to rely on the only communal access to the Internet, which was the computer lab where the class was conducted. Due to this reason also, the use of social technologies could only be considered as complementary due to limitation in its ubiquitous access.

5.0 Contributions, limitations and future research

The use of social technologies for educational purposes has changed the demands and direction of higher education. Lecturers are now being encouraged to use social technologies in their teaching in order to encourage social learning and to prepare students as graduates who will contribute to a society that now relies heavily on social technologies. From the evidence provided by the two lecturers in this paper, we found that OSN activities were used to complement current teaching and learning practices. The combination of one or more social technologies in enabling one or more OSN activities also demonstrates the confidence of the lecturers as well as the relevance of social technologies to support teaching and learning.

This paper enriches the current literature on the use of social technologies for teaching and learning which is still emerging. It also contributes to practice by providing empirical evidence of how social technologies can be appropriated successfully for harnessing teaching and learning in the higher education context as well as highlighting the benefits and challenges faced by lecturers in their use of OSN for teaching and learning. We have demonstrated that the selection of social technologies and the appropriation process are very much based on the preference of the lecturers. Thus, the wide range of social tools that are available as well as the flexibility offered by the tools to support various uses and applications may require creativity and innovation from the lecturers to appropriate the preferred technologies to support their specific needs.

There are some implications of this study findings for other lecturers and potentially, educational designers in planning, designing and using social technologies for their purposes. In particular, lecturers could consider taking up the systematic process of using OSN by meticulously planning and conducting for (a) pre-implementation analysis of students preference and learning styles, (b) conducting a formal evaluation of social technologies such as via SWOT analysis, (c) designing how OSN could be used for classroom environment, and (d) assessing the effectiveness of OSN use to ensure the teaching and learning practice achieves the intended learning objectives. For educational designers, the lessons learnt from the benefits and challenges of lecturers in using OSN activities to enhance teaching and learning should become the key pointers for them in enhancing and improving OSN for educational purposes. While many social technologies were not designed for educational purposes, this paper demonstrates they can be appropriated for teaching and learning with support of educational designers. To address the challenges such as the low level of familiarity in using certain social technologies for teaching and learning, educational designers could engage lecturers and their students in training sessions to give them the opportunity to familiarise themselves with the system design, features and usability of the social technologies. The limitation of this paper is attributed to its localised context of Malaysian universities and the limited number of cases which may affect its applicability in other contexts. Thus, more cases of appropriating social technologies for teaching and learning in various universities and in different countries would be useful to complement the findings of this study. In particular, cases that demonstrate both successful and unsuccessful uses of social technologies for teaching and learning would be valuable to increase our understanding about the appropriate use of social technologies in higher education. Future works could be geared towards developing a 'toolkit' that could assist interested lecturers to easily and systematically use social technologies for their teaching and learning.

Bridging the Gap between OER Initiative Objectives and OER User Needs in Higher Education

Amal Hanna
School of Communication, International Studies and Languages
University of Australia

Denise Wood
School of Communication, International Studies and Languages
University of Australia

The *Open educational resources* (OER) movement is a new phenomenon in the field of education. Increasing use of Web 2.0 technologies along with growing competition between educational institutions have accelerated interest in the potential of such '*open*' educational resources. Some educational institutions have made their learning resources available online for learners for the purpose of encouraging knowledge sharing and improving effectiveness of teaching and learning. Furthermore, some community organisations are also hosting and supporting OERs. However, at least some reports from educational institutions indicate that the motivation behind this move to OERs might be driven more by a desire to enhance their reputation and attract new students to their programs, rather than the promotion of OERs. This paper presents the findings of a content analysis of a sample of OER websites undertaken to identify whether 'Net Gen' learner needs are adequately addressed by current OER initiatives. The findings suggest that although many educational institutions state that their OERs allow learners to share knowledge and extend critical thinking and interactivity, the OER community organisation sites reviewed appear to be offering learners greater opportunities for online interaction, critical thinking, and reflective learning practices than the formal educational institutions reviewed. The findings of the content analysis also suggest that OER initiatives do not necessarily meet learners/users' needs. The findings from this analysis are discussed and the implications for future uptake of OERs as a strategy for supporting widening access to education in response to the changing needs of learners are explored.

Keywords: Open Educational Resources, Initiatives, Web 2.0, Open Content, Qualitative Analysis, Electronic Learning, Interactive Learning, Learner Needs.

Web 2.0 technologies have opened up new opportunities for users to generate content and engage in collaborative efforts involving content sharing. Such Web 2.0 technologies are also gaining increasing acceptance in learning and teaching because they facilitate activities that 'enable learners to take control of their own education' (Franklin & van Harmelen, 2007, p. 21). 'Net Gen' learners, those born in the 1980s and after, are said to display certain learning characteristics such as preferring non-linear access and processing of information, multi-modal learning and learning activities that are active rather than passive (Oblinger & Oblinger, 2005). However, the literature suggests that there may be a 'mismatch' between 'Net Gen' learner and teacher expectations, and that new approaches are required to bridge this gap between the needs of learners and teaching practice (Kennedy et al., 2009). One of the emergent trends in response to such changing demands has been increasing interest in the potential of open educational resources for learning and teaching activities.

Open educational resources (OERs) have gained increasing attention because of their promise and potential for promoting individualised/personalised learning practices and facilitating lifelong learning. OERs, and more specifically wikis, are regarded as potential solutions for increasing access to education for learners from different cultural and/or socially disadvantaged backgrounds. This is because wikis support multiculturalism, do not require high technological specifications, and satisfy different user needs (Hanna & Metzer, 2011a, 2011b). Furthermore, more advanced Web 2.0 technologies and 3D Virtual Worlds can support the widening participation agenda for people in remote areas, and also learners with disabilities who may find it difficult to participate in on-campus learning activities (Wood, in press).

This paper provides an overview of the nature of open access and open content educational resources, the premises on which OERs are based, and the challenges facing the OER movement in a period of transition. The finding of a comparative review of OER initiatives, which considers OER objectives, target users, the nature of materials, and learners' FAQs, are presented. The assessment of OER users' needs and OER objectives provides insights that offer greater insight into whether there is consistency in the stated aims and achievement of objectives. Addressing these differences can help bridge the gap between the needs of learners and the OER services provided by educational institutions.

What are Open Educational Resources (OER)?

Open educational resources are electronic materials that are offered freely online for users. These materials include learning modules and content management systems (Hylén, 2006), which may be either open access (OAER) or open content (OCER). Open access educational resources allow learners to access and use educational content without (or with limited) restrictions. Open content educational resources allow users (including self-learners, students, and educators) to participate in the production of content, while also using and re-distributing the content. Figure 1 shows the process of production of OERS and illustrates the differences between open access educational resources and open content educational resources.

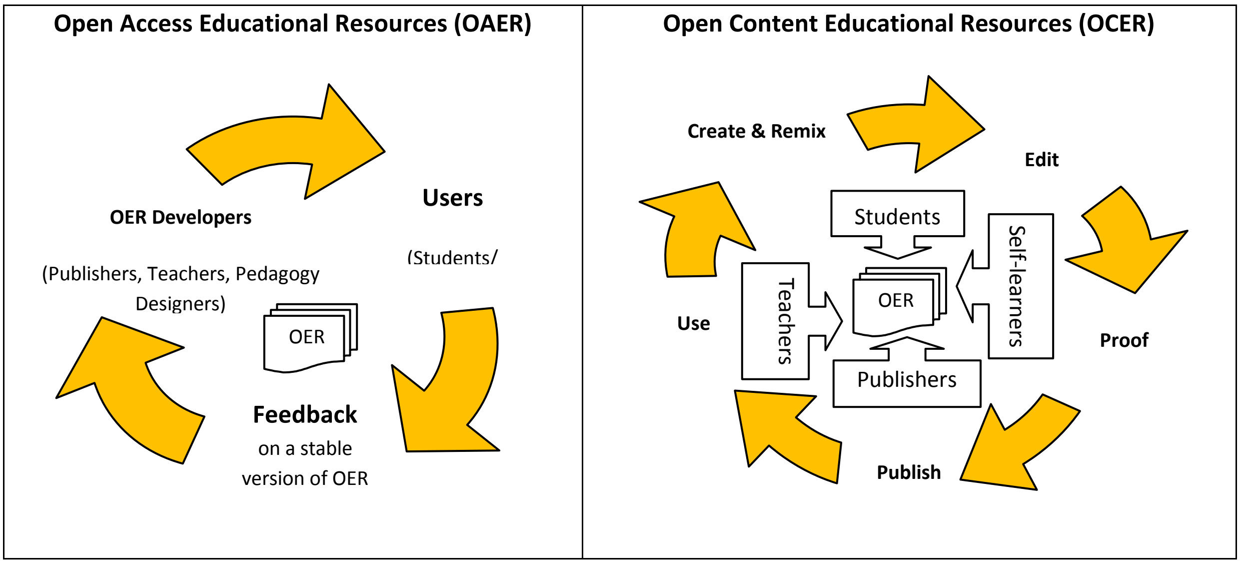

Figure 1: Production process of open educational resources

While OAER initiatives have contributed to the founding of OER repositories and have provided ongoing maintenance for host servers and content management systems, OCER initiatives also play a significant role in facilitating interaction, supporting production, and encouraging collaboration. Assessment of and discussion about the activities of some of the players in the OER market, as demonstrated in this paper, supports this view.

The goals of OERs

The primary goal of making educational resources 'open' through the use of Web 2.0 technologies is to disseminate and share knowledge for free (Yuan, MacNeill, & Kraan, 2008). Thus, OERs provide users with freedom from financial commitments and freedom from restriction of access (following Stallman, 1999). One of the fundamental basic rights articulated in the United Nation Declaration on Human Rights is that education should be (or shall be) free for all individuals (United Nations, 1948). OER initiatives, therefore, have the potential to provide the medium through which such democratisation of education can be achieved by providing 'a strategic opportunity to improve the quality of education as well as facilitate policy dialogue, knowledge sharing and capacity building' (UNESCO, 2011).

Grosseck (2009, p. 482) points to the growing uptake of the use of Web 2.0 technologies to enhance teaching and learning activities. He argues that the benefits of Web 2.0 facilitated activities include reduction in the cost of education, increased flexibility, ease of access to information, and the promotion of innovation. The 'knowledge-in-action' movement (Richards, 2009) supported by different applications of Web 2.0 has also contributed to the drive to 'reflective learning'. For example, Ras & Rech (2009) have found that the use of Web 2.0 technologies in education can significantly increase knowledge acquisition. The 'positive transfer' of learning *experience* instead of the 'negative transfer' of *knowledge* learning (Elgort, 2007) is one of the major reasons cited for incorporating Web 2.0 technologies in learning and teaching activities. As Bruns (2007, 2008) suggests, such technologies enable users to actively contribute in their capacity as product users, or 'produsers'; a term Bruns uses to describe the move towards community-based production, fluid roles, unfinished artefacts, and common property.

Many argue that the quality of OERs is indeed increasing, driven by 'open' market competition (Vukovic, 2009). It is argued that teachers and learners who are involved in the production of OERs, are motivated by 'altruistic ambitions', such as assisting developing countries and providing outreach educational services to disadvantaged communities (see for example GTP, 2005), while financial reward has been argued to be the least important motivating factor (Hylén, 2006, p. 6). Research undertaken to date suggests that the motivations of teachers and learners for using OER vary. For example, the findings of a quantitative study published on the OERCommons website (OERCommons, 2010c) suggest that students are using OERs to complete their assignments (9%), while self-learners either want to learn a new topic or expand their knowledge (~59%) or to stay current (~36%). The findings further suggest that teachers are using OERs to gather ideas for their lessons (~35%), to supplement their lessons (~30%), or to improve their teaching methods (~28%). It is apparent from these studies that the reasons for using and interacting with OERs differ according to the varying needs of different users. These findings illustrate that while learners use OERs to complete their assignments and expand their knowledge, teachers use OERs to learn new ideas for their lessons and improve their teaching methods; but both learners and teachers appear to also want to stay current and have the opportunity to network with others (Metzer & Hanna, 2011).

Hylén (2006) suggests that competitive educational institutions embark on the use of OERs for differing reasons including: 1) learning from the community about what courses work and which do not; 2) providing rapid diffusion of their courses; and 3) seeking different revenue models. However, the question remains as to why community organisations also become involved in the OER movement? Moreover, one might question whether there any differences in the reasons for user interactions with OER between OER initiatives, and further, whether there are differences between the motivations of users and the ways in which OERs are used in educational institutions and community organisations. Do OER initiatives satisfy OER user needs? Are there any differences between the explicit OER objectives documented via OER websites from the underlying implicit objectives? Regardless of whether the providers of OERs are educational institutions or community organisations, the nature of content production is argued to be the key issue in assessing objectives of OER initiatives against OER users' needs. To answer such research questions, a content analysis of a sample of OER websites was undertaken.

Method: Content analysis of OER initiatives

The main focus in content analysis of websites is not only on the technical features of the website, but also on the message form and the content, with a 'diagnostic-eye' on such matters as links, spelling, browser compatibility, image optimisation and accessibility (Newendorf, 2002), assessment of company's policies (Polariski, 2007), security, visual appearance, convenience of order process, information quality, responsiveness (accessibility of service and contact information) and interactivity (Chiou, Lin, & Perng, 2010). In other words, website content analysis has to date largely been a matter of evaluation. Gibson *et al.* (2003), for instance, applied comparative content analysis to assess party political election websites. Schweitzer (2008) found that websites of minor parties were underutilising the standard functions of websites, while major parties ran e-campaigns through sophisticated and interactive functions. While such studies may be useful in their own right, this project demands a different orientation. If website content analysis is to collect evidence of information presented to its users, then it should also be possible to use website content analysis to collect data for analysis focusing on an examination of the stated explicit objectives of OER initiatives and whether these objectives are met.

This study involved firstly identifying OER websites via a web search. From the relevant sites identified, a semi-random sample (Bourgeron, Humphries, & Jensen, 2001; Sim & Wright, 2000) of websites was chosen for further analysis. The comparison of OER initiatives involved establishing the following research criteria:

1. **The OER site stated objectives:** Content analysis involved assessing the stated objectives taking into account target users and the nature of OER materials available from the website.
2. **Target users:** Each OER website, either implicitly or explicitly, has identified target users. Understanding which users the site targets help in the assessment of the rationale of the OER initiative.
3. **Technology:** An analysis of the technology employed and features of the OER websites was undertaken to determine whether the objectives of initiating the OER are achievable. For example, if an OER website aims are to enhance collaboration among learners, but the technology employed in the website does not facilitate collaboration, there is very little likelihood that the stated objectives can be met.
4. **The nature of resources:** The educational resources available from OER websites might include textbooks, audio/video materials, simulations, course guides, educational games and educational software. Furthermore, these resources might be *open access* or *open content*. Content analysis therefore involved both identifying the nature of resources available and determining whether these resources can be characterised as being either open access or open content.
5. **The FAQs:** Since there is no way to survey users and understand their needs, the content of their frequent asked question help in understanding these needs. The questions by themselves are meaningless, so answers are represented to show common themes of needs of learners.

Results and discussion

The comparison of the selected OER websites is presented in Table 1. The analysis was based primarily on examination of each website's home page, the about-us page and the FAQs page. Other pages within the website were reviewed when more information was required for the purpose of comparison.

Table 1: A comparison of OER websites

OER	**Open Content Educational Resources OCER**	**Open Access Educational Resources OAER**
Website	**Connexions**	**OpenCourseWare**
Objectives	Connexions aims to encourage collaboration and of information sharing among learners, scientists, and people who do not read and write English, to address the increasing cost of textbooks, to make educational texts available to learners to access, and to reduce the time between production and distribution of textbooks (Connexions, 2010e)	To unlock knowledge, empower minds and help people who are socially disadvantaged. MIT, by launching OpenCourseWare, sought to enhance its reputation. Users are able to reuse the content providing they acknowledge OpenCourseWare (OCW) authors (MIT OpenCourseWare, 2010g).
Users	Authors who collaborate and create content, instructors who build and mix collections, and learners who would like to explore content (Connexions, 2010b).	The courses are available for any self-learner who would like to know more about the subject. However, learners are not awarded academic credit by MIT (MIT OpenCourseWare, 2010d). Learners of these courses are global and include: North America 40%, Europe and Russia 20%, East Asia 20%, India 8%, North Africa 5%, and Sub-Saharan Africa 1% (MIT OpenCourseWare, 2010e).

Technology	CNXML & MathML in addition to MS Word Importer (Connexions, 2010c). Content is open to learners as open access, however, in order to create content, an account must be opened. Creation of content is open to anybody. It is preferred that content is created in small modules since small modules make it easier for users to remix (Connexions, 2010d).	Static webpages, files available for download in Microsoft Word, PDF and in compressed zip files by clicking on 'download course material' link on the left menu (visit this course for example MIT OpenCourseWare, 2010f).
Resources	Textbooks (scholarly content) on which users can collaborate, from children to college students to professionals (Connexions, 2010a).	High quality open access courses which users can access. Resources include: course description, syllabus, lecture notes, readings, and assignments (MIT OpenCourseWare, 2010a). This website consists of different courses at college (university) level. These courses are available for open access by self-learners.

FAQs	Once they have accounts, OER authors, who are mainly professors and teachers, can create educational materials. Only authors can edit their created modules. However, users can make a copy of existing module and edit it as needed and republish it. Teachers and lecturers can customise their learning materials by mixing modules together to create new books, courses, syllabuses, and lessons, and to meet different learning styles of their students. Teachers cannot, however, test their students using quizzes or exams. There are options for self-assessment available for students. Students and self-learners can read and use these created modules. Connexions provide open educational resources that are free to use and reuse around the world. It supports different languages and different educational levels across more than 190 countries. OER brings people back to education. OER also help potential authors to publish their work (especially k-12 teachers, scientists, engineers and people who do not read and write English). The recognition that authors receive for their published work 24/7/365 universally is a great incentive. OER also help solving the high cost of textbooks (average cost $120). It helps by bringing current knowledge to learners instead of out-of-date of printed materials. In order to help users to find quality materials they need, connexions is developing a system that help authors to setup their own review process, and directs users to the content that	The use of MIT OpenCourseWare is free and no registration is required. MIT OpenCourseWare does not provide quizzes and exams; MIT faculty publishes content only. Only a few video lectures are available because production of video materials is very costly. Non-MIT-Students cannot have access to course-pack materials because they are copyrighted. Only copyleft materials are openly available to MIT OpenCourseWare users. MIT OpenCourseWare is not distance learning, so no degree, credit, or certificate can be obtained. However, those who wish to be MIT students, they need to contact MIT Admissions Office. However, in case of that organisations or teachers use MIT OpenCourseWare materials, acknowledgment should be made. Any translation to other languages should be accompanied with a specific MIT OCW disclaimer. MIT OpenCourseWare does not offer users the opportunity to contact MIT OpenCourseWare authors, as it does not involve interactive experience. Materials in MIT OpenCourseWare are openly available to users for non-commercial educational purposes. Materials on MIT OpenCourseWare published by their MIT staff only since MIT take the final responsibility of their materials. No download, copy, modify, reuse, remix, and redistribute MIT OpenCourseWare materials should be made without permission from the

	judged to be 'high quality'. This is done through allowing users to tag and comment on modules. Connexions allow dynamic, interconnected and engaging environment since it helps learners, students, authors and instructors to communicate cross-institutions and worldwide. (Connexions, 2010e).	copyright owner. MIT also offers OCW Scholar courses which are designed specifically for independent learners, hoping that learners provide their feedback and suggest ways to reshape content. These OCW Scholar courses are elementary courses. There are some messages and announcements from other MIT programs on MIT OpenCourseWare pages. (MIT OpenCourseWare, 2010c).
Website	**Wikibooks**	**OLI**
Objectives	To provide open books for an open world. To create free content in terms of freedom and money. To give back to humanity and help others. Teachers can use customised textbooks for their students, and learners can challenge themselves by making contributions. Authors can publish their books (Wikibooks, 2010c).	To allow independent learners to access open and free resources (material and activities). To allow instructors to build and customise their courses (OpenLearning Initiative OLI, 2010e, 2010f).
Users	Self-learners, instructors, institutions, and authors (Wikibooks, 2010a, 2010c).	Students, instructors, and institutions wishing to actively engage their students in material in various ways (OpenLearning Initiative OLI, 2010g).
Technology	Wiki which supports multilingualism	HTML, Java applets for simulations (see for example OpenLearning Initiative OLI, 2010b; 2010h which involves a simulation). This website has two groups of courses. The academic courses are not visible to self-learners. Students who have invitations can enrol when they enter the course keys. The free courses are open for any learners.

Resources	Open content textbooks that anyone can edit. These resources include: textbooks, annotated text, instructional guide, and manuals which all are instructional material (Wikibooks, 2010d).	Courses available are classified into two types: 1) Academic courses that are designed by instructors to create customised courses for their students. Low per-student maintenance fee (student may pay these fees on enrolment in their institution). Students can access instructors. There are graded exams. Instructors can trace student learning (OpenLearning Initiative OLI, 2010a, 2010e); 2) Open and free courses, which are designed for self-learners who are not supervised by instructors. Users are free either to register or anonymously use the content. There are no fees, tests or quizzes (OpenLearning Initiative OLI, 2010c, 2010f). All courses include course materials, computer simulations, course schedules, computer-based tutors, virtual laboratories, and self-assessment modules.

FAQs	Wikibooks aims to create free educational resources. Anyone can contribute to Wikibooks. Users of Wikibooks can download any content they like, and printing any book is also welcome by clicking on 'Printable version'. Users can communicate with other users through email lists. They can leave messages on talk pages of other users. Registered users can communicate with other registered users who have registered their email addresses by clicking on 'Email this user'. Users can contribute without having accounts; however, signing up with an account gives a registered user many benefits such as positive reputation of quality work. IP addresses of registered users remain unknown. While users, who seek recognition for their contribution, can use their real names, registered users are not required to use their real names. Users can change their pseudonym to their real names by 'Request for renaming' if they want. There is no mechanism to ensure that information in Wikibooks is correct and current since any one can edit. However, because there are many contributors, incorrect information is usually edited quickly. Users can create their own textbooks, guides, and manuals in Wikibooks. Debates and discussions are welcome in discussion pages as they help to improve content. Users, by contribution to Wikibooks, make information resources free to access. Contributions are being updated on ongoing basis which means they receive built-in feedback on their contributions.	OLI offers two kinds of courses: 1) open and free courses which allow a) access to resources, b) simulation and self-assessment, c) formative feedback to students; 2) academic courses, which in addition to the above listed affordances, also allow d) access to instructors, e) graded exams, and f) credit for course completion. OLI courses are offered based on education research: choice of and content of the courses are determined on the basis of empirical studies or the findings of evaluations. These courses are continuously updated based on feedback from instructors and students obtained through formal evaluation studies. Users have the right to opt-out from such studies. OLI expresses interest in working with teachers who would like to be part of ongoing evaluation and would like to adapt OLI courses for better teaching experience. Although accessing open and free courses does not require that users have an account, it is recommended that users create accounts to allow them to track their progress. Academic courses require registration. OLI does not grant any credit of any course. However, those who undertake Arabic courses can receive credit from the institutions of their instructors. OLI users who undertake free courses can download grade book results as a proof of their completed courses, but this does not grant credit (OpenLearning Initiative OLI, 2010d).

	Wikibooks considers users who have dial-up connection, so there is a limit of 30 KB of page size. The site provides features that are aimed at preventing or limiting acts of vandalism (such as deleting paragraphs from a webpage) and also a facility enabling users to recover texts. Logged-in users can track certain pages if they add those pages to personal 'Watchlist' by clicking on 'Watch this page' link.(Wikibooks, 2010b).	

An increasing number of educational institutions have embraced the OER movement in response to the rapid evolution of information technologies, globalisation and its impact upon economy and social life, as well as the growing competition between educational institutions (Wiley & Gurrell, 2009). Such factors have encouraged educational institutions to be part of the 'open' movement. Although some educational institutions, such as Carnegie Mellon University and Massachusetts Institute of Technology (MIT OpenCourseWare, 2010b; OpenLearning Initiative OLI, 2010g) have made educational resources available online for self-learners and students around the world, these resources have largely remained open access, rather than open content.

The reasons, whether explicit or implicit, for providing educational resources online for students and self learners vary, but centre around the following: 1) To encourage collaboration and knowledge sharing; 2) To make positive use of technology and allow wider access to information; 3) To maximise the impact of individual research by allowing individuals to publish their research; 4) To extend research; 5) To improve teaching and learning effectiveness; and 6) To foster critical thinking.

Table 1 shows that while some of the institutions included in this study demonstrate altruistic motivations for participating in the OER movement (for example, the provision of educational resources for the public good), the findings from content analysis suggest that they are also seeking social and economic benefits (see also McAndrew et al., 2009). Such social and economic reasons for developing OERs include: 1) Developing the institution's reputation and enhancing recognition; 2) Other implicit motivations, which 'might' include advertising their fee-based courses and their methods of teaching and learning inside the university; 3) Increasing earning revenue by selling their open course materials to instructors if they wish to re-use the content; and 4) Developing course materials for the public to edit and speed up the development of courses, whether for internal purposes or for external re-use. Examples of those institutions that seek financial and social reward are MIT and OLI. Organisations such as Connexions and Wikibooks that freely make their resources open to edit and re-mix, also make revenue by selling printable versions of textbooks and from accepting donations. These forms of revenue are important to ensure their sustainability. The most important issue is freedom in terms of money and contribution. The findings also suggest that some of the OER initiatives that are hosting quality educational resources are publishing their OER materials with minimum editorial assistance at a fee to cover their operating costs.

The findings also suggest that the reasons for users accessing and editing educational resources include: 1) The desire to acquire knowledge for free; 2) They are inspired to share their knowledge with others; 3) They seek to publish their work to receive recognition; 4) Editing OERs increases their understanding through peer review; 5) OERs help users to develop their networks through emailing authors, and communication via discussion boards or discussion pages; 6) They want to help others, especially those who are economically disadvantaged, or giving back to their community. Teachers appear to be using OERs to: 1) Develop their customised course materials; 2) Re-use the available content with some minimal restructure and editorial effort, thus saving them time; 3) Engage their students in the production of knowledge as constructive teaching methods and gaining feedback on student progress; 4) Enable students' collaboration; and 5) Encourage students to translate, which may lead to localising knowledge according to society's needs, and enhancing the students' reflective learning.

The analysis of objectives for those who initiate OER and responses to FAQs show that they differ from those of OER '*produsers'.* Such analysis demonstrates that although some of these objectives are clearly stated, the content analysis suggests that OER educational institutional initiatives are not maximising the affordances of sites to meet the target users' needs (see Table 2).

Table 2: Objectives of OAER educational institutions and a critical assessment of achievement for OER *users*

OAER Education Institution Initiatives	Learners (mainly users ONLY)
Enhance the community	Learners are part of the community and their skills indirectly help to develop the community. However, users perceive that the attainment of certification/qualifications is still important. This is understood from questions, published in FAQs pages on institutional OERs, from learners about whether they will be able to receive certificates for courses they studied or not (MIT OpenCourseWare, 2010c; USQ OCW, 2010).
Unlock knowledge	Although learners are able to access information and learning materials, they are not able to share information and discuss issues and problems because most of institutional OER are only open access rather than open content.
Increase the university's reputation	Evidence suggests that by initiating OER activities, the university's reputation may be enhanced. However, do users really care about the university reputation? Furthermore, since users appear to be concerned about the need to attain formal recognition through their participation (MIT OpenCourseWare, 2010c; USQ OCW, 2010), the benefits for universities may not be fully realised.
Advertise their courses	Users who seek OERs look for free courses (or free sources of information). New comers to the for-fee courses, who visited the free courses, are willing to pay and the free courses they use are 'test-drive' offerings (MIT OpenCourseWare, 2010c; Open Michigan, 2010; Open Yale Courses OYC, 2010a, 2010b; USQ OCW, 2010).

Enhance research skills	Since the institutional hosted OERs reviewed are open access and do not allow contribution and collaboration between members of research groups (to identify problems and seek solutions), the potential for supporting the development of user research skills is limited.
Develop critical thinking	It depends on tasks provided in those courses. The development of these skills would be further enhanced if the OER websites provided opportunities for discussion and feedback.
Allow collaboration and networking	In most cases, courses are '*open*' in terms of open access, and the opportunities for collaboration are reduced in sites that do not provide communication tools such as wikis and discussion boards
Develop learning and teaching methods	Some institutions allow teachers to reuse material (with special acknowledgment).

Table 2 indicates that the potential of the sites in achieving some of their stated objectives are not fully realised because of the identified limitations. Educational institutions could benefit from incorporating some of the features of not-for-profit (NFP) OER initiatives. Table 3 illustrates the objectives of NFP OER initiatives and the corresponding achievement of users' needs.

Table 3: Objectives of NFP OCER initiatives and a critical assessment of achievements considering the OER *produsers*

Non-for-profit OCER initiatives	Learners (and they also can be *produsers*)
Unlock knowledge	This objective is likely to be achieved since users can be proactive in creating and sharing content and they can reflect on their understanding and share their experience in the content.
Foster openness	The sites reviewed maximise the affordances of the open content movement by enabling users to edit, share, use, reuse, remix, download the content without (or with minimum) restrictions.
Increase research skills	The openness, and the ability of collaborative writing and sharing information, as well as discussions, allow users to develop their research skills
Enhance collaboration	The sites reviewed employ features that maximise the affordances of collaborative learning environments by providing opportunities for collaboration through discussion pages, discussion boards, built-in messengers, visible email contact of users, and wikis (or any similar technologies).

Develop learning and teaching methods	This objective is facilitated by enabling teachers to use the content, reuse, and remix. Learners are also to edit content and share their experiences supported by the collaborative nature of the sites.

This paper identifies two kinds of OERs: OAER and OCER. The findings from comparative analysis of these different OERs suggest that education institutions which produce and host OERs, are offering OAER for learners, while community organisations that are responsible for maintaining and running content management systems for OERs are showing a greater trend towards supporting OCER. As discussed in this paper and shown in the preceding comparative analysis, the objectives for not-for-profit (community) OER initiatives differ from educational institution OER initiatives. Furthermore, the findings of the OERCommons survey (OERCommons, 2010a, 2010b, 2010c) suggest that teachers are using OERs in their teaching and learning activities for a variety of reasons. Teachers derive both direct and indirect rewards from such involvement. Such rewards might include career enhancement as future contributors in the 'open' movement. Moreover, since remixing and editing requires time and effort, '*produsers'* may undertake these activities to make their time more productive. It might be argued that those self-learners who want to learn without necessarily attending school, may be seeking more productive use of their free-time. Moreover, as with not-for-profit organisations, some OER websites publish photographs and information about socially disadvantaged areas of developing countries (GTP, 2005), and in this way motivate users to contribute to the OER movement to promote social justice.

Conclusion and areas for further research

This paper highlights the increasing interest in the use of OERs for teaching and learning activities. Since, as the literature suggests, 'Net Gen' learners have a preference for active and collaborative learning, it is reasonable to expect that OCER initiatives are more likely to meet their needs than OAER. Although OER initiatives aim to make educational knowledge available for free to learners, as outlined in the objectives of institutional OER and NFP OER initiatives, the findings from this study demonstrate that open content OERs potentially hold additional benefits for their users than open access OER alone. Since OER users are demanding more benefits for themselves, such as developing creative thinking skills, unrestricted access to knowledge sharing and collaboration, the future of OER will be for open content material, not for open access material alone. Universities, schools, and research institutions need to be prepared for such a transformation of learning materials to meet the changing demands of learners in a knowledge based society.

Although this research did not survey or interview contributors to the OER movement or users of OER sites themselves, the analysis undertaken of users' FAQs provides some insight and understanding of their needs. This study is also limited by the small sample of OER sites included in the analysis. Moreover, the study would be strengthened by incorporating inter-rater reliability reviews of the sites. Future research involving interviews and focus groups with OER users, both teachers and learners, would help to provide greater insight into the benefits of OERs in teaching and learning. Despite these acknowledged limitations, the study has highlighted areas for further consideration by educational institutions that are positioning themselves to respond to the changing demands of 'Net Gen' learners and the widening participation agenda.

Implementing e-learning: A migration story

John Hannon
Curriculum, Teaching and Learning Centre, La Trobe University

David Hirst
Curriculum, Teaching and Learning Centre, La Trobe University

Matthew Riddle
Faculty of Law and Management, La Trobe University

The shift to an open source learning management system (LMS) raises questions for the integration of technology and pedagogy in an institutional approach to e-learning, and for strategies to build effective student learning through staff development. Implementation at La Trobe University involved the migration of over 1300 subjects to Moodle by the start of Semester 1, 2011. This paper describes this process as a migration story in which successful implementation is a necessary but not sufficient stage to achieving an effective e-learning strategy, in this case, one that meets particular pedagogical needs by embedding pedagogical choices that match the blended learning needs of a multicampus university. The risk is that implementation defaults to technology requirements, and is enacted in a way that pre-empts and sets the conditions for academic development in e-learning. This paper examines the ambiguity of "implementation" that arises from the separate goals of LMS configuration and pedagogical needs.

Keywords: e-learning, learning management system, Web 2.0, academic development,

Background

This paper describes the university-wide implementation of the open source learning management system (LMS), Moodle 2, at La Trobe University for the commencement of Semester 1, 2011. The e-learning environment at La Trobe University presents a complex, multicampus environment, with a student population of 29664 (in 2010) distributed over two city and four regional campuses (69.9% at one city campus), for which a primarily blended learning approach is adopted for undergraduate degrees. This learning environment includes large student cohorts (over 1000 students), and subjects that are taught simultaneously over several campuses.

The LMS implementation occurred as a response to external contingencies, and the consequent choice of LMS involved a level of institutional risk: support for the existing LMS was to cease at the end of 2010, and Moodle 2 was a first-time installation in an Australian university. In this context, implementation was structured as a content migration project, managed externally by Netspot, and modelled in part on the implementation of Moodle at the University of Canberra (Carter & Arnold, 2009). The project aimed to migrate or transfer all subjects from the previous LMS to Moodle for use at the start of Semester 1, 2011, and to train as many academic staff as possible to a level of minimal functionality of Moodle.

This paper aims to raise the questions about implementation that are directed towards establishing sustainable e-learning in the university: what does implementation entail when it is scoped beyond functionality? How should staff development and support be designed if it goes beyond a technology training program? Will an LMS migration project default to a transmissive pedagogy, or can migration embed pedagogy as well as content into e-learning?

It's not purely technical

The commitment to e-learning by universities is shaped to a large extent by economic imperatives and the potential of information technologies for massification and extending learning over distance (Goodyear & Ellis, 2008; Snyder, Marginson & Lewis, 2007). It is not surprising, therefore, that as LMS have become mainstream in universities over the last two decades, there has been a tendency towards the "management system" aspect of the LMS and a transmissive approach to learning (Lane, 2009; Bayne, 2008; Malikowski, 2008). This emphasis is currently under challenge with the advent of Web 2.0 and PLEs (personalised learning environments) (Downes, 2010; Mott, 2010; McLoughlin & Lee, 2010), nevertheless, the use of LMS broadly reflects what Goodyear and Jones (2003) identified as a "default pedagogy" (p. 40) based on "access" and a functional transmission of content. In this approach, the technological *how* may come to shape the pedagogical *what*. The persistence of the troublesome accommodation between technologies and practice in e-learning is captured by Blin and Munro (2008), who comment that despite the investment in LMS in universities:

> there is little evidence of significant impact on teaching practices and current implementations are accused of being focused on improving administration and replicating behaviourist, content-driven models (p. 475).

The issue with institutional learning technologies arises when their implementation is framed by technology system requirements that exist prior to a project and set conditions for e-learning. In this instance of implementation, there were technical and external imperatives for instigating a university-wide migration project, hence a critical goal was for the new LMS to be functional and usable for all subject university wide. A migration project implements a model of minimal, or "interoperable change" (Marshall, 2010, p. 180), rather than disruptive or transformative change. From the broader perspective of institutional teaching and learning strategies, however, LMS functionality and usability are really a means to student learning, hence the challenge remains for staff to be able to integrate the new LMS into their teaching practice, and incorporate academic goals into e-learning. Function is not enough to address this challenge.

The migration story

The strategy for implementation of Moodle at La Trobe University was framed as a content migration project which aimed to achieve widespread technological functionality with minimal staff disruption. A program of staff communication and training included these components:

- Preparing teaching staff by migrating their subjects in the new system without effort on their part. Staff were encouraged to postpone development of new or revised subjects.
- Staff support and training consisting of a program of workshops for staff from November 2010 until the week prior to Semester 1 in late February 2011. Attendance for these workshops indicated that 48% of academic staff completed the Moodle basics workshop (see Table 1).
- Staff support and training that included the production of 26 guides in PDF format, 15 two minute short videos, demonstrations, student "rovers", staff drop-in centres (La Trobe University, 2011)
- Student support via a Help desk, Student guides (PDF and HTML), and Video Guides.

Table 1: Moodle training workshops and participation

Training workshop session	Academic staff
Moodle basics:	1239 (48%)
More Moodle - Groups & Groupings	171 (6.7%)
More Moodle – Quizzes	142 (5.6%)
More Moodle - Gradebook	139 (5.4%)
More Moodle - Assignments & Turnitin	34 (1.3%)

Initial reports in early Semester 1 on the content migration project indicated success in functional terms: the system remained stable at times of critical use, for instance, in the first week and on the due date of the first assignment.

The content driven model: Implementing what?

Implementation of institutional e-learning necessarily involves trade-offs and negotiations between competing institutional and pedagogical goals (Marshall, 2010; Uys, 2010). This instance of implementation was determined by contingencies that required a fast-track process of content migration to the new LMS. With the selection of Moodle occurring in June 2010, the system becoming available to users for subject development in October 2010, leaving little time and few resources for familiarisation and subject development. These implementation demands – for full functionality of Moodle across the university by the start of Semester 1, for widespread but minimal training – overshadowed or postponed the opportunities for a more pedagogical approach to e-learning staff development, and for exploring the potential for an open source LMS such as Moodle for incorporating uses of Web 2.0 and social media. The goal of large-scale migration framed implementation as a "content-driven" model, conducted through an information technology (IT) project management process, raising questions concerning the type of e-learning that is produced or put in place on completion of the migration project, and how technology and pedagogical design can work together to build an environment for effective student learning.

Professional Development: A model of ownership, excitement and engagement

If the above outlines an information technology (IT) approach to LMS migration, including a tools training component, then the question remains: What kind of academic staff development should be pursued once the migration team has moved on?

What we propose as a follow-up to the migration training is a reaction against the dull, under resourced, IT-driven, passive service approach. It is more than just advocating a pedagogical stance. It is about academics taking ownership of what they do, carefully crafting a pedagogy adapted to a very flexible medium, and adding excitement, engagement and specificity to a bland institutional environment. To encourage ownership and unique pedagogical craftsmanship we outline the following important elements:

26. **Learn by doing**: rather than academics having things done for them, for example content upload or the creation of discussion forums, academics should design the learning themselves.
27. **Scaffolding professional development**: lecturers would 'do it themselves' but in consultation with staff such as academic developers, learning technologists, educational designers, and/or media production staff.
28. **Adopt a project approach**: Part of the mechanism that enables scaffolding and assistance is the means by which support staff can walk academics through the process of creating a learning design and implementing a constructively aligned learning environment. Adopting a project approach provides a formal methodology that facilitates professional development and learning environment creation. The project could be very small scale and not too onerous in its implementation. Process and product must be balanced.
29. **Provide a creative environment**: The first three points need to be packaged within a creative environment to encourage expansive thinking and novel solutions. The lecture-tutorial paradigm has a history that is centuries old in higher education, so its abandonment (or supplementation) requires creative use of the digital medium. The promotion of an open source-open course set of values also encourages an expansive mode of thinking (see below).

Sometimes criticised as a "cottage industry", implementations of this approach, such as the Courseware Design and Development Program at the University of Melbourne (Hirst et al, 2004), have demonstrated that enough academics participating in the program can produce a critical mass of people creating interesting and engaging learning environments. Models can then be promulgated and adapted, but with a specificity of creative expression that the institution has always allowed and encouraged of its individual academics in teaching.

Zooming out to a broader view than assisting the individual academic, there is a role to play for a central university unit and local faculty staff working in cooperation to scaffold the learning. A network of centre to faculty and faculty to faculty cooperation provides the broader framework for strategic developments to live alongside individual initiatives. Top-down and bottom-up can co-exist where values embrace the contribution each can make to the e-learning experience. Such a mutual compact is also dependent on each side acknowledging the contribution the other can make.

The OE Model: Open Source, Open Course

Alternative approaches to the adoption of e-learning via the content model described above have been enthusiastically adopted for some time now. MIT's Open Education (OE) is a celebrated demonstration of one such model, and extends the concept of open source software to educational resources in order to revolutionise the way that students, academics and institutions interact (Baraniuk, 2008, p 229). Since 2001, MIT has been sharing its courseware online through its OpenCourseware project, and at the time of writing has published more than two thousand courses, with a hundred million visits recorded (MIT OpenCourseWare, 2011).

Cambridge University is one institution to adopt this approach to the provision of e-learning resources. The Centre for Applied Research in Educational Technologies (CARET) provides Cambridge with its LMS, Sakai, and supports this through the active involvement in the Sakai developer community. CARET's e-learning strategy takes the view that technology changes rapidly, and is expensive, and that online learning is unlikely to be a major component of face-to-face learning. It therefore adopts an approach to "operate as an innovation unit" by identifying and developing innovations that make learning better or easier, and "support R&D with University learning and teaching innovators".

Australian universities have by and large been slow to adopt an OE model that goes as far as MIT's, and few have even gone as far as Cambridge in making innovation a truly central component of the support for their LMS. Indeed, OE as a philosophy is about more than choosing an open source LMS, just as there is no necessary connection between choosing an open source LMS and adopting OE values as an institution. However, the recent adoption of Moodle in a number of institutions such as La Trobe may signal a step towards the support for innovation, if (a necessary if) open source technologies are used to extend OE values to the educational experience.

Conclusion: Challenges for implementation

While academics are expected to be proactive and reflective in their teaching practice in face-to-face settings, why is it often acceptable for them to passively assign tools in an e-learning environment? Critical to the approaches outlined above, both learning by doing and the OE model, is the provision of an opportunity to explore potentialities of e-learning, by establishing a supported space of conversation and innovation around student learning goals. Where information technology goals frame implementation, the complexity of e-learning in a university is dramatically reduced, but at the cost that pedagogical choices are presented in packaged form, and innovation is pre-empted and foreclosed. The challenge for the OE model of e-learning starts *before* the technology arrives, to re-scope implementation to encompass the pedagogical effort and learning goals of its practitioners: teaching academics, academic developers, learning technologists, and educational designers.

The Middle East Politics Simulation (MEPS) is a simulation of diplomacy and political tension in the Middle East. This online role-play exercise is aimed at providing students with an improved level of understanding of the political dimensions of the region. Having been run since 1993, the MEPS has not had any major updates to its platform in all those years. However, as such a mature online entity there is the question of whether the MEPS will continue to engage students as their expectations of what constitutes an online role-playing environment became steadily raised by their familiarity with more graphically immersive platforms. The reliance on social media tools for students and political figures to use as conduits for communication is also unrepresented in the MEPS and the subject of some student dissatisfaction in previous years.

This research assesses student attitudes towards the MEPS with an eye to balancing the demands of technology, functionality, equity of experience, security and, most importantly, learning outcomes.

Keywords: Role-play, social media, simulation, student engagement, politics, Middle East

Background

In deepening student engagement the use of role playing simulations is well established and known to offer positive outcomes in the teaching of Politics and International Relations subjects (Asal, 2005; Boyer, Trumbore, & Frick, 2006; Chasek, 2005; Hintjens, 2008; Sasley, 2010; Simpson & Kaussler, 2009). The Middle East Politics Simulation (MEPS) is a successful example of such a role play. A simulation of diplomacy and political tension in the Middle East, the MEPS is an online role-play exercise aimed at providing students with an improved level of understanding of the political dimensions of the region. The students take the roles of various political actors concerned with the Middle East and their lecturers perform the function of "Controllers", generating initial story lines, adjudicating and facilitating the simulation.

The intended purpose of using this form of role-playing exercise in delivering Middle East Studies subjects is to demonstrate the complexity of political dialogue the practical challenges and compromises that face the actors in this part of the world. Throughout its history, the developers and convenors of the MEPS have believed that this large collaborative exercise offers a deeper and broader comprehension of these realities in comparison to the more theoretical understandings that may be gleaned from a traditional assessment task such as an essay (Vincent & Shepherd 1998). By using an online platform to deliver the MEPS, the exercise can run 24 hours, thus deepening the immersion level further, as well as allowing the participation of off-campus students and those from other universities.

The MEPS has been running since 1993 and is currently administered by Deakin University, although other universities regularly participate. A text-based environment, the MEPS is viewed on a web browser over the public Internet and the site is accessed by a login/password barrier. Still operating through a low-bandwidth, simple HTML interface, the current MEPS system has had no significant upgrades since its original roll-out, the platform having been built as part of an Honours project by a computer science student at UNSW.

With such longevity, the MEPS has survived many trends in technology, e-learning and distance education in Australian universities. Literature describing the MEPS has consistently indicated the high level of student engagement and learning outcomes (Dracup, 2009; Hardy & Totman, 2011 (forthcoming); Ramsden & Watson, 2003; Vincent & Shepherd, 1998). Moreover, it has served as an exemplar for a subsequent generation of role play tools utilised in Australian tertiary teaching (Wills & McDougall, 2009).

The utility of the MEPS as a learning tool therefore seems apparent and its continued use desirable. However, as such a mature online entity, the convenors wondered whether the challenge of engaging students might increase as their expectations of what constitutes an online role-playing environment became steadily raised by their experiences with more slick and graphically driven tools. Even the very term 'simulation' occasionally causes confusion because in the popular mind a simulation is something more visual, for example a flight or driving program. Likewise, the phrase 'online role play' also conjures impressions of more immersive visual environments along the lines of World of Warcraft or Second Life.

Another omission from the MEPS platform is the sort of micro-blogging or file sharing tools associated with social media or Web 2.0 trends. At the time the MEPS was created, such functionality was unknown to the majority of the population, as indeed was the World Wide Web itself. Today though these tools are ubiquitous and to some extent *de rigueur* for inclusion in any web-based environment, particularly one that is principally concerned with communication.

So given these real and supposed short-comings, is it time to update the MEPS or is it a case of not needing to fix something that isn't broken?

The Status quo

The MEPS site is extremely serviceable but lacks some of the visual polish and functionality that the current generation of university students might expect. It is fundamentally an email emulator with some extra functions attached, such as an area to view news, a section for posting role profiles of the different teams, a diary/sandbox for intra-team communication and a live chat tool.

The core function of email emulation is fully serviceable and does not tend to cause any major complaints or problems. There are some slight visual issues caused by students pasting material out of Word documents, causing 16-bit characters like curled apostrophes to display as strings of symbols, but this cannot be classified as a serious impediment to functionality. Nor are there any consistent problems with other text publishing functions of the site, such as the diary or role profile tools.

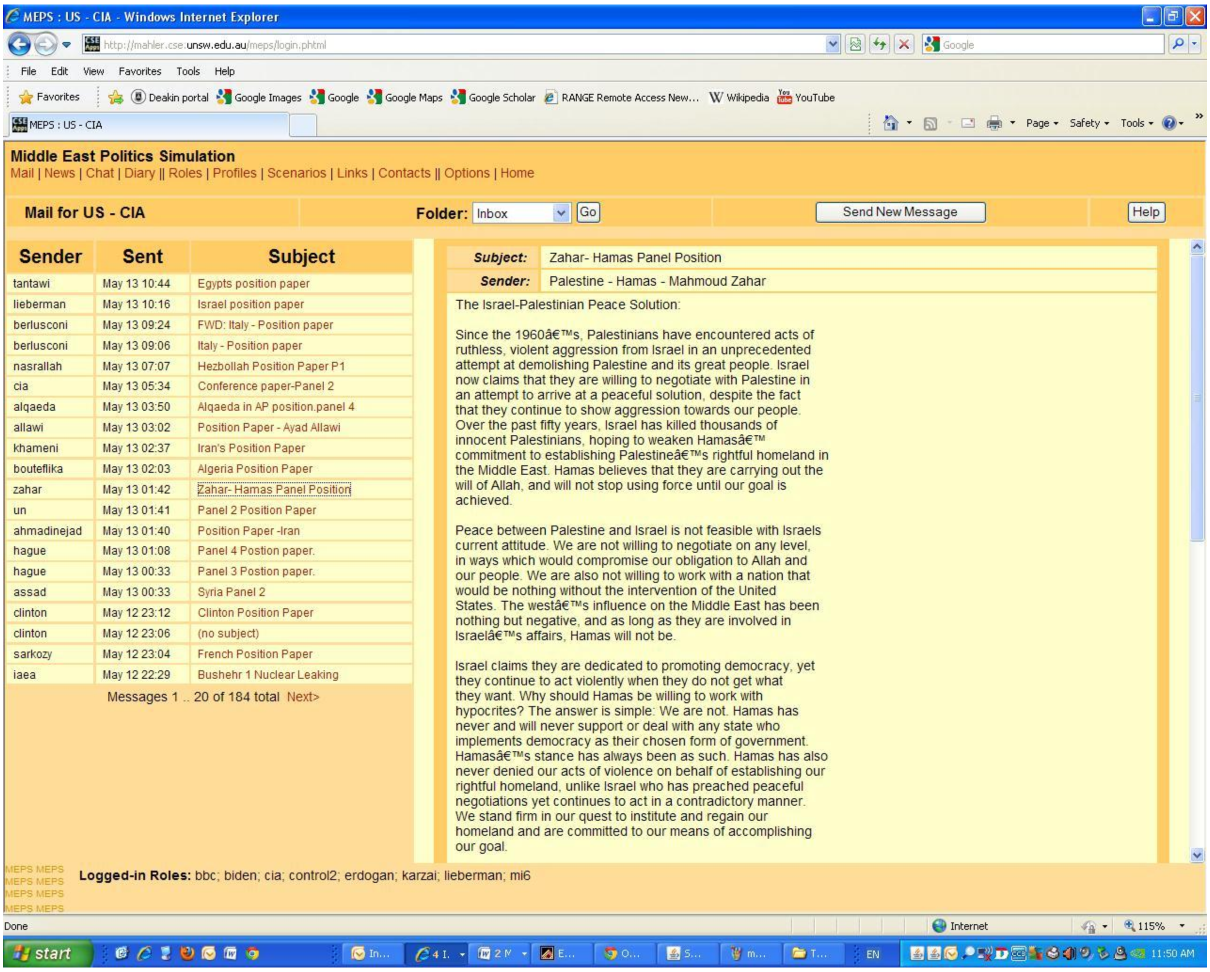

Figure 1: Screen view of a team Inbox in the MEPS

There are however two issues that do cause some annoyance each time the MEPS is run. The first of these is a steadily increasing incompatibility with each advancing version of Internet Explorer. This causes some areas of the site not to display properly, depending on the user's IE version and operating system. Naturally this can be completely avoided by encouraging the use of alternative browsers such as Firefox, but not all students have the skills for installing such software, nor is it necessarily an option for those using shared or public computers.

The second area of concern is the chat function. The chat tool pre-dates most commercially available instant messaging clients and therefore lacks many of the benefits of what would today be conventional wisdom. The three chief grievances with the MEPS chat tool are (a) that users must refresh the frame manually to see new messages/replies; (b) anyone in the MEPS can enter a chat session so there is no way of guaranteeing confidentiality between teams; and (c) navigating away from the chat window breaks one's session. Users who return to the chat window will then be re-logged as a new user identity, differentiated by a number. For example, obama1, obama2, obama3. Confusingly, the old user identity still remains visible in the session participant list, even though it is now inaccessible.

This is extremely problematic because participants in a chat do not have the option to check back to their emails or refer to other material without breaking their session. In a large chat session, the window quickly becomes full of notifications of duplicate user identities entering and leaving. Occasionally it can become so unstable that the entire session crashes.

Figure 2: MEPS chat window showing broken session

There have also been some regular expressions of yearning to add Web 2.0 functions such as micro-blogging or Facebook-style updates and file sharing to the MEPS. Partially this stems from an assumption that students use these things in their private lives and therefore might expect their inclusion or that the availability of these things will make the MEPS more enjoyable for them. However, it increasingly needs to be considered that in a world where senior politicians and even terror groups make full use of the Internet to post their opinions or Tweet, such social media tools are now actually a legitimate aspect of simulating political discourse.

On the other hand, increased functionality and its demands can alienate those students who are not as comfortable with using such tools or have no desire to use them in their studies. Given the growing weight of evidence disputing the Digital Native hypothesis (Cameron, 2005; G. Kennedy, et al., 2007; Kvavik & Caruso, 2005) the provision of extra functions within the MEPS may generate inequalities between users and raise levels of anxiety about what is already quite a daunting exercise.

The purpose of this research is to therefore to assess student attitudes towards the MEPS, both in terms of the experience they have with the current system and with what they believe should be added in future iterations. The core concerns of our research is the need to balance the demands of technology, functionality, equity of experience, security and, most importantly, learning outcomes.

Specific challenges

Any overhaul of the MEPS will face the generic challenges involved in the development of any online learning tool. These would include the pedagogical questions surrounding learning experience, scaffolding and instructional design, as well as the technological issues of platform, stability, access and of course, budget. Since these factors are so ubiquitous and applicable to any new implementation, it is not worthwhile dwelling on them within this paper. However, there are some specific obstacles that the MEPS gives rise to through the nature of its content and game mechanics. These do need to be considered since they are fundamental to both the long-running success of the simulation, as well as any future re-versioning.

The first difficulty that the MEPS faces with any design or upgrade is the nature of its content. The plotting of terrorist acts, violent responses to them and anti-Western (or anti-Semitic) rhetoric is an everyday occurrence within the simulation. Students are playing the roles of terror groups, intelligence agencies and state representatives and communication 'in character' is the whole point of the exercise.

Such content needs to be carefully quarantined from the outside world lest it be taken out of context. The Australian Security Intelligence Organisation (ASIO) is informed when a MEPS session is running so that if their electronic intelligence gathering is alerted by the simulation's traffic, an explanation is available. Participants are also asked to sign a pledge not to discuss the simulation's 'events' through any channel outside the MEPS site, except between their university domain email addresses. This legal proviso was instituted in 2009 after an incident where a student text messaged her team-mate regarding their plans for a bombing attack on a mosque. Regrettably she used the wrong number and the message was sent to a member of the public who then alerted anti-terror authorities. The matter was cleared up though not without the student and one of the convenors facing some unsympathetic interrogation from the police and the university's legal department.

This incident provides a salient lesson on the need for keeping the MEPS secluded from public channels. This includes being cautious about mixing the MEPS with the university's LMS and/or email system. At present it is impossible for a MEPS email to travel outside the interface, even accidentally, since with the bespoke email emulator there is no such connectivity for this data.

Secondly, the team assessment nature of the MEPS requires provision to be made for joint account access. At present team-mates share a username and password to access their account. This is another barrier to utilising the university's LMS, since it would require the creation and sharing of accounts not associated with real individuals. Moreover, because the MEPS regularly involves students from other institutions, this would require them having access in the same manner. Such obstacles are not insurmountable, though it can be imagined that organising this through the multiple stakeholders in a university IT system would generate some degree of extra administration. (Conversely, the fact that the MEPS has sat within an obscure UNSW domain server for all its life is perhaps responsible for its lack of evolution, in that it has not been necessary to adapt across the two or three different LMS versions that most universities have been through over the last 15 years.)

Thirdly, the mechanics and assessment of the MEPS require that the controllers be able to see all emails sent or received by the teams. This is for purposes of grading their role-playing. At present this privilege does not require extra log-ins for the controllers, but is achieved through a dropdown menu. Again this poses a technical challenge to using some off-the-rack solutions or an LMS.

Lastly, the size of the MEPS in terms of teams and participants is large and varies from session to session in terms of exact team numbers and team identities. Since the simulation is used across different units of the Middle East Studies major sequence at Deakin, there are different emphases in different sessions. For example, in the second trimester of every year, one of the units (The Politics of Terrorism) has a much greater stress on terrorist groups and this entails creating team roles that are not present in trimester 1. Moreover, the identities of the team roles can change as politicians and groups come and go in the real world. Lastly, the number of users, teams and members per team needs to adapt to cohort enrolments, students opting to undertake the MEPs as their main assessment task and other variables. In the last five years student numbers in any MEPS exercise have ranged from 120 to well over 200 in a trimester.

All of these potential variations mean that any MEPS platform has to be scalable and flexible enough to adapt to what is essentially a unique run for every session.

These four main concerns form the context in which any potential upgrade to the MEPS system needs to be examined within.

Question and methodology

Given that there are some known technical issues with the MEPS an upgrade does seem desirable. However some of the other reasons for considering an upgrade are based upon supposition, such as an assumed student desire for social media type tools. With this in mind, it was decided to survey students as to their experience with the MEPS and their thoughts about what features they thought would improve the simulation.

A questionnaire comprising open- and closed-ended responses was utilised for canvassing student opinion on the MEPS. This method was employed as it provided the best opportunity to sample large numbers of students.

Gathering a large number of responses was deemed desirable because the complexity of the role play (100+ students, 60+ teams) offers such a range of individual experiences that a smaller sample (such as a focus group type-approach) would have been much less representative and/or to complex to make representative. Additionally, given that the MEPS requires over two weeks of effort by the students, requesting more of their time to participate in follow-up research would seem unreasonable.

Deakin students who had completed the first trimester 2011 run of the MEPS (2 – 13 May 2011) were asked to complete a written questionnaire. This posed a variety of questions about the quality of their experience in a mixture of closed and open-ended questions. They were asked open-ended questions about what features they would like to see added to the MEPS and on their likes and dislikes about the simulation. There were 58 completed responses from 64 students who were given the survey.

By gathering this data, the researchers hoped to ensure that any decisions they made about changing the MEPS system had some supporting evidence behind them.

Limitations

The questionnaires were handed out during the final part of the MEPS exercise, which is a face-to-face role-playing conference. This sample therefore excluded some students who had participated in the longer online part of the exercise but could not attend the conference. Some of these were off-campus students or those who had other commitments. Around 30 students were excluded in this way.

As the final part of the assessment, this sample group also excludes anyone who had such a negative experience of the MEPS that they had abandoned their participation in it at an earlier point. This would include approximately five students.

The questionnaire was not given to the 16 or so students from Charles Sturt University (CSU) who had also participated in this iteration of the MEPS, filling the roles of newspaper journalists. The reason for excluding the CSU students was because their participation in the exercise was under fundamentally different assessment criteria, with different expected learning outcomes and under the direction of teaching staff not otherwise linked to the MEPS. For example, the CSU students participated in larger teams and were being assessed by their tutor on their journalistic and print production abilities. The central aim of their participation was to hone their skills as journalists rather than deepen their understanding of the Middle East.

Results and discussion

The results of the questionnaire illustrate three main trends:

1. Student experience with and attitude toward the MEPS is overwhelmingly positive.
2. The current interface is deemed simple and suitable, though a majority of users see room for improvement
3. Most users would like to see some social media (or Web 2.0) tools included in the interface, with an improvement in the chat function being the most common desire.

Student experience

Amongst the 58 respondents to the questionnaire 57 nominated their overall experience with the MEPS as being positive. (The single respondent not counted in this majority was one who did not answer the question.) Every respondent described their learning experience in this exercise as ‘Excellent’ or ‘Good’, with all but two (who did not answer) rating the MEPS as offering a ‘Much Better’ or ‘Better’ learning experience than traditional forms of assignments they had encountered. Over 90% felt that their understanding of the Middle East and their engagement with the subject had been increased by their participation in the MEPS.

Such results are consistent with previous research on student experience with the MEPS. Dracup (2009) found a similarly high level of student experience and satisfaction. Over 95% of respondents in that study expressed the opinion that they had “a better understanding of the facts of Middle East politics” as a result of undertaking the MEPS. That research also suggested that students felt they had seen an improvement in more generic academic skills such as creative thinking, communicating, team work and problem solving.

One contrary, though not necessarily negative viewpoint that was expressed in our questionnaire was the volume of time that the students felt they had put into the MEPS. Many noted the time demands of the MEPS as being considerably greater than they would normally devote to a university assignment. This has been noted in prior studies too, with a figure of about 3.5 hours per day being recorded as a typical student input whilst the MEPS runs. (Vincent & Shepherd, 1998)

It should be noted that the nature of the comments made in the questionnaire about time demands did not always indicate deep resentment or negativity, with many of them being along the lines of "I want my life back" or "My brain is dead!". Evidence that the time requirements were not begrudged is offered by the fact that 50 out of the 58 respondents indicated that they would participate in another MEPS if they had the chance.

The interface

Questionnaire responses were mixed regarding the need to change or upgrade the MEPS interface. Fifty-one respondents (88%) felt that the current interface was 'Suitable for its purpose'. However, this is contrasted with the lower rate of 67% in another question who felt that the current interface was 'adequate for the task', with several making informal notations in the margin in the vein of "Adequate, but could be better". This was also indicated in the response to the question regarding whether the interface needed to be improved, where 40 participants (69%) wanted to see improvements, with another 6 (10%) being undecided.

Visual appeal was not deemed important by the participants in the survey, with only 39% being in favour of making the interface 'more attractive'.

In terms of usability, the interface's simplicity was widely acknowledged by students. The majority (90%) agreed with the statement "The interface is simple". In free comment spaces of the questionnaire though, a few respondents noted specific functions or elements that they felt were complex or unintuitive. The email inbox and filing system was mentioned by nine respondents in this regard. The convenors would note however that some teams had a disorganised approach to their email inbox and failed to make any use of the folder creation functions that the emulator offers, which are very similar to those found on commercial mail clients.

Web 2.0 tools

One question in the survey asked students to agree, disagree or indicate indecision to the statement "Social media tools need to be added to the interface". The specific types of social media tools were not nominated by the questionnaire. To this question, 37 (64%) respondents indicated that they felt such tools did need to be included. Only 13 (22%) disagreed with the statement, with the rest being undecided or failing to answer the question. It is important to remark that amongst those stating a desire to see more social media incorporated, six respondents indicated in margin notes next to this question that it was solely the need for a better chat function that they were referring to. (See discussion below.)

The results from this question seem to indicate that a desire for greater social media presence is not automatic amongst students, even those sitting quite firmly in the demographic usually associated with such platforms. In the case of the MEPS, this may be because they recognised the unsuitability of social media elements to the task or perhaps because they thought it would add to the workload. Regardless of the reasoning, this question in our survey was the least clear cut in its response and would seem to accord with much of the research refuting the Digital Native hypothesis and the desire for social media presence in classroom activities. (G. Kennedy, et al., 2007; G. E. Kennedy, Judd, Churchward, Gray, & Krause, 2008; Kvavik & Caruso, 2005)

Criticism of the chat function of the MEPS was the most prevalent negative comment garnered by the questionnaire. This was expressed in various free form comment boxes as well as informal marginalia. Students were frustrated by the unreliability of the chat interface, its inability to be kept open when referring back to other site elements and the need to refresh the window in order to see replies. Some respondents also lamented the unavailability of an 'out-of-character' chat function, particularly so that team-mates could communicate synchronously.

This last wish may have been made more imperative in the last two years given the ban on students communicating via other channels, such as text message. Currently the only way team-mates can communicate with each other in anything approaching synchronicity is to arrange to be online simultaneously and then send emails to themselves or leave notes in the team's diary and constantly refresh the page. Both of these options seem rather awkward, especially given the ubiquity of chat functions in so many other online environments.

Another desire expressed by some students was an ability to attach files to emails within the simulation or at least some other ability to share files between team-mates or with other teams. This warrants consideration, but the question arises as to what sort of files might be exchanged and how this might be affected by institutional policies on appropriate ICT use and the need for security of material generated by the MEPS. For example, a seemingly benign use of such file attachments might be for a team to create their own letterhead for the issuing of press releases and thus send them as an attachment to teams playing media roles. However this gives rise to the issue of terror-related material ‘leaking’ from the MEPS as discrete files when created on one student’s computer and potentially downloaded onto another’s, where it could then be forwarded on outside the context of the MEPS. Likewise it would be possible (or even likely) that some students might send graphic or inappropriate image files to each other, particularly regarding terrorist actions. Whilst this can likely be covered by instituting rules or policies, the potential for mishap needs to be weighed carefully against the need for such file sharing functionality in the first place.

A further disincentive for instituting file sharing or enhancements beyond the text-based nature of the MEPS is in providing equality amongst participants. Currently the interface and entirely online nature of the task means that all students participate equally, regardless of their location, bandwidth, computer equipment or study mode.(Hardy & Totman, 2011 (forthcoming)) Allowing students to create and attach files might give a perceived advantage to those with the skills, equipment and inclination to do something beyond the scope of the average participant. Naturally this may be seen as a meritorious endeavour, but with the focus of the MEPS being on understanding the politics and diplomacy of the Middle East, the creation of additional media objects by students is not a target outcome.

Conclusion

It is obviously important to take notice of the expressed need for a workable chat function in the MEPS. The simulation cannot continue running with this element so badly broken, or at least not without it affecting levels of engagement. This will either entail a complete re-write of the chat function within the existing system or else a move to a new platform.

These results on the whole though suggest that a major upgrade of the MEPS interface is not imperative and that in any subsequent version care must be taken to preserve the simplicity of the system. Developers of online role play tools would do well to bear in mind this trade-off between simplicity and feature provision as it seems that students appreciate usability and ‘fitness for purpose’ over complex and ‘well-appointed’ interfaces. Naturally they would prefer to have both outcomes, though the nature of educational design and development rarely affords such unrestricted possibilities. The implication is that when designing something like an email system, it is not necessary to be concerned that the tool does not completely emulate the features and functions of a commercial email client. As long as the tool is adequate for the job, students understand that ‘bells and whistles’ are superfluous and their level of engagement is not affected.

The Virtual Worlds Working Group began with the DEHub research consortium in November 2009. In December 2010, New Zealand joined the VWWG. This paper highlights the current work of the NZ based members of the group and presents the work of 23 authors at 11 institutes of higher education in New Zealand. The scope of the work covered is diverse, and a number of platforms have been used. Virtual worlds enable educators to provide realistic simulations, engaging role-plays, immersive and genuine tasks, and social interaction that encourages group collaboration, and highlights the ability that virtual worlds have to transform both teaching and learning.

Keywords: virtual worlds, *Second Life, Reaction Grid, OpenSim*, immersion, engagement, VWWG

Introduction

He ara hou ka tū mai means "A new pathway before (us)". This Māori phrase succinctly summarises the position in which NZ educational institutions find themselves. As digital literacy continues to increase in importance as a key skill in every discipline and profession (New Media Consortium and EDUCAUSE Learning Initiative, 2011, p. 3), so the demands of our students and the demands of education precipitate us along this new pathway into virtual worlds.

"Virtual worlds are richly immersive and highly scalable 3D environments. People enter these worlds via an avatar which is their representation in that space". (New Media Consortium and EDUCAUSE Learning Initiative, 2007, p. 18) Virtual worlds offer educators a graphically rich, immersive and engaging environment where students can engage in role-plays, simulations, data visualization and modelling.

Salt, Atkins and Blackall (2008) described the sense of shared experience, immediacy, and the resulting social and emotional sharing, which facilitate group and collaborative learning in Second Life (SL), a virtual world used extensively by educators. In the EDUCAUSE Review, Marina Bers suggested that there is a change and shift in education from the idea that knowledge exists in an individual to a community of learning and this change can be seen in virtual world education. This spirit of educational collaboration led to the birth of the Virtual Worlds Working Group (VWWG).

In November 2009 the VWWG was formed from the initial institutions that comprised the DEHub research consortium: University of New England, Charles Sturt University, Central Queensland University, University of Southern Queensland and Massey University. Other Australian institutions were invited to join and by July 2010, the membership had increased to 22 members. On 7 December 2010, NZ joined the VWWG. Currently the total membership of the VWWG stands at over 150, with New Zealand having 31 members from 16 institutions. Membership is diverse, including lecturers, researchers, technicians, developers and administrators. Members contribute a wealth of expertise in various fields of endeavour, and assist each other in research initiatives, shared classroom experiences, presentations and publication.

This paper outlines the use of virtual worlds in many New Zealand institutions. The examples represent a diversity of research, experience, and perspectives. But the common element is the belief in the efficacy of virtual worlds for education and their potential for meeting the changing demands of a digitally challenging world. Virtual worlds have enabled the provision or resources, experiences, and learning that would have been difficult and sometimes even impossible to provide in the traditional classroom environment.

New Zealand Institution Vignettes

The following table summaries the current work being done in virtual world education by a number of New Zealand institutes of higher learning. Educational demands in New Zealand are changing rapidly and this table suggests ways that institutions are changing directions in response to these demands.

Institution -*Where*	**Project Intent**	**Process**	**Outcome**	**Future plans**
MIT *Purpose built sim: Kowhai on SL Movement into Jokaydia Grid & NZVWG*	Student interview skills for Foundation students Career pathways	Interview aspects, dress, simulated interviews in purpose built rooms (as shown in *Fig 1*)	Engaged students, retained students, more merit passes	Use by other departments Literacy game
University of Auckland – Health *Purpose built health clinic: SL*	Simulation for undergraduate nursing students	Simulation involving three active student nurses with patient and family member, plus other students observing	Thoroughly engaged students Debrief ensured learning of key points.	Have used the setting for other simulations Waiting for faster broadband before exploring extending further
University of Auckland – Architecture *Purpose built sim: Putahi on SL*	Give studio based experience to acquire digital skills in a virtual urban-like building site called the Living Sketchbook	Creative Digital Studio space for the first imaginative steps needed to design and build architecture	To 'get over the interface' and arrangement of the complex information flows of image and building design and construction	Ongoing survival and acceptance of virtual worlds/3d web rather than "SL" Continue development of the Living Sketchbook
Massey University *Customised Open Wonderland world hosted on university server*	Create a virtual workshop for teaching agile software development methods	Run workshops, observe and interview participants	Useful feedback for future design iterations	Benchmark performance and utility against other open source virtual worlds
Massey University – Auckland School of Design *Biofeedback augmentation, (Fig 2) Blender, Unity & Flash in lab & online*	Adapting interfaces for virtual world use (Champion & Decker, 2010)	1. Biofeedback sockets to augment gameplay 2. Combining mirror and code 3. Chinese character sketching 4. Unity run inside Moodle	1. Utilised in architecture 2. Projection of virtual environs 3. For learning Chinese 4. Running a virtual world inside an LMS	Extending work in creative interfaces
Waikato – School of Arts *Garry's Mod, a modding application for Half-Life 2 & its associated community and wiki*	Transferability of learning from creative practice, the role of machinima as a filmmaking tool, and mode of engagement with gaming technology	Workshops, utilising regularly updated user-generated content and solution based engagement to realise a film concept	Short film as a creative output (*Fig. 3* as an example) Further knowledge of game engines and modding practices	Consolidate and shift modding environments into purpose built open-source machinima applications
Waikato – Education Faculty *Intermediate schools in the Hamilton region – MARVIN (Fig. 4)*	Classroom-based research exploring using avatars to help develop student key competencies	Interviews, observation, screen capture software, video	Higher order thinking skill development. Increased collaboration. Enhanced awareness of local issues	Extend research to other school levels

University of Canterbury – Computer Science Education *On OpenSim portable server for use within schools*	Using virtual worlds to evaluate and deliver CS Unplugged activities (*Fig 5*)	School students participate in activities and their actions are captured for analysis	Experimental system still being developed for monitoring activity in SL	Complete experiments and see if evaluation in SL can inform evaluations in the physical world
University of Canterbury – Literacies & Arts in Education *OpenSim Server on campus – nominally part of NZVWG*	How to use MUVEs effectively in vocational education contexts	A MUVE for temporary traffic management instruction is being developed through design based research	This partially developed scenario is part of an on-going research project	On going research
Wellington Polytechnic *SL – Koru Kowhai Island* *OpenSim Server on campus – nominally part of NZVWG*	Authentic learning of technology & architecture Exploring dance, human senses and technology Using the virtual environment as a development tool	Computer Architecture course Dance - digital sensing of human data Designing prototype environments	On going achievement of learning outcomes Performance at Digital Resources for Humanities and Arts 2011, and on going collaboration	Continuing current projects Continuing collaboration on an international level
Auckland University of Technology– Languages *Purpose built sim: Kowhai on SL & exploration of cultural sims throughout SL*	Undergraduate: Experiential intercultural learning and language learning Postgraduate: virtual worlds for language learning, teaching and research	Undergraduate: ethnographic studies in a range of cultural sims Postgraduate: enquiry based learning; development of core knowledge	Undergraduate: critical awareness of own identity and culture; effective communication for relationships, Postgraduate: educational potential of virtual environments	Undergraduate: Develop exchanges with other universities Interdisciplinary studio model Postgraduate: possibly integrate into other courses
AUT - Computing & Mathematics *1) Prototype Java 3D CVE 'Teamlink'* *2) UpStage an open source web-based platform for cyberformance (http://upstage.org.nz/blog/)*	Aid learning and research into global virtual teams and collaborative technologies	1. Global virtual collaboration – ongoing development 2.Undergraduate projects working in partnership with the UPStage Virtual organization to extend UpStage software	1. Challenging learning experiences in CVE development, and collaborative technologies 2) Intriguing learning experiences, including open source development	1. Possible porting to a browser based technology stack - new global collaborations 2. Continuing developments and enhancements for annual performance festivals
Auckland University of Technology– VR Suite *AUT VRSuite, Colab http://vr.colab.org.nz/*	More effective VR research by sharing of resources and expertise An interface to aid industry in undertaking 'research of value' in interactive 3D	Exploration of varied 3D applications in a number of contexts such as rehab, advertising, interactive art, etc Complex data visualisations of natural disasters	Enjoyable learning experiences, clever algorithms and visualisations, useful research outcomes linking 3D technology and contexts	Industry linked research -human full-sensory perception and interrogation of complex information driving complex processing and modelling

University of Otago *Otago Virtual Hospital (OpenSim)*	Professional identity development of medical students	Medical students solve clinical cases while role-playing as junior doctors in virtual emergency department	To solve clinical case, students needed to notice clinically salient elements by themselves (Blyth, Loke, & Swan, 2010)	Assessment of dispositional behaviours as a measure of professional identity
Nelson Marlborough Polytechnic – IT *Koru and Kowhai in Second Life,* *Korako on JokaydiaGrid,* *NMIT sim on NZVWG,* *Sim on a stick* *Kitely*	1. How to build and script virtually, create communities of practice, and create machinima 2. Studying Systems Development Methodologies	1. Investigate viewers and grids, taught in SL how to build and script Final assignment built in chosen environment 2. Design & build a complex virtual word build	1. Understand the purpose and affordances of virtual worlds 2. Complex development process using established methodologies and adapting and innovating where necessary	More of the same. Keeping abreast of this technology and its implications (e.g. 3D web sites etc) is essential for future IT professionals
NMIT – Languages *As above*	Students learning English (at NMIT)	Early stages - using NZ themed immersive space for conversation	More comfortable role-playing and trying new skills as an avatar	Provide 'authentic' spaces for language learning

34. **Figure 5: UoC – Unplugged activities**

Themes

Several themes emerge in the work of the institutions reported in Table 1. These include the following:

The students who are working in virtual worlds demonstrate a high level of immersion in the tasks they are challenged to complete. MIT report that students involved in the SLENZ (Second Life Education NZ) Project reported a sense of immersion which was supported by anecdotal evidence (Winter, 2010) and this immersion was reported in SL classes subsequently. Waikato Faculty of Education describe improvements in student social interaction, and the increased involvement of 'peripheral' students in general classroom activities.

A common theme in the majority of the vignettes in this report is that what is impossible for students in the real world, becomes possible in the virtual world. Making the impossible, possible, is often associated with simulation builds. The University of Auckland has simulations for maternal haemorrhage, paediatric bereavement, nursing and pharmacy and the University of Otago has a virtual hospital in which medical students play the role of junior doctors/housemen. Students are provided with safe and authentic learning experiences.

The ability to provide the previously impossible is also indicated in many Arts courses, eg. the architecture students from the University of Auckland, Computer Science students at Canterbury University, WelTec, and NMIT are all able to pursue projects made possible by virtual worlds. Language tutors report this same advantage of virtual worlds. Japanese students at AUT are able to go to the Japanese sim (virtual build) to interact with native Japanese speakers for an engaging and very real experience. It is possible for these students to not only engage in the previously impossible, but build networks and establish a sense of community at the same time.

The sense of community is another main theme indicated by the work of these NZ educators. There is group connectivity between educators and students in virtual worlds. This is seen in the VWWG itself where collaboration and community is seen in the huge growth of participating institutions. Links are reported between architecture students at Auckland University and Technology students at WelTec and between WelTec students and NMIT students. Several projects reported in Table 1 are part of international collaborations, eg, WelTec with dance instructors and students in Portugal and Japan, and AUT 'Teamlink', a global collaboration including NZ and Sweden. The sense of community is vital for students in the performing arts, with AUT students involved in UPStage relying on an online audience that participates via a browser, and the machinima (derived from machine and cinema) produced by arts students from Waikato Student is exhibited publicly online (e.g. www.selectparks.net, www.machinima.com).

Designing creative software solutions is another theme that is evident in the work reported in Table 1. Examples of this work include many of the IT courses, eg. Massey University examining techniques of agile software development in a game based activity, Massey's Auckland School of Design researching interfaces that can be adapted for virtual worlds, WelTec using virtual worlds as a development tool for creating prototype 3D interactive environments, the AUT Faculty of Design and Creative Technology's continuing investigation of 'Teamlink', a prototype Java 3D CVE, developed to aid research into global virtual teams and collaborative technologies, AUT's VRSuite, CoLab examining the use of interactive 3D technologies to aid industry, and NMIT where students are creating applications in complex immersive MUVEs as well as gaining an understanding and appreciation of the communities, the potential benefits and issues of working and operating in these environments.

Higher level critical thinking and reasoning skills can be developed within virtual worlds, as indicated by the work in creative software solutions. Real-time problem-solving is a common theme in virtual world education. Virtual environments that contain game elements frequently rely on real time problem solving. MIT's proposed literacy game will challenge students to solve grammatical problems. MARVIN, utilized by the Waikato University Faculty of Education, when used in small group settings, supports discussion, debate, critique, organisation and presentation of researched information through the exercise of higher order cognition (analysis, evaluation, creation) (Falloon, 2010). The prototype traffic management scenario being tested by the University of Canterbury requires surveyors to produce a traffic management plan for when they are working on a road.

It is also important to note that a number of tertiary institutions working in virtual worlds are working in conjunction with other sectors. Waikato University Faculty of Education has used MARVIN in trials with two Intermediate schools (Years 7/8) in Hamilton. The trials have concentrated on identifying any role the application might have for supporting the development of selected key competencies as outlined in the revised New Zealand Curriculum (2007). The Computer Science Education group at the University of Canterbury is interested in using virtual worlds to collect information about how learners interact with educational material. The main focus of the group is the CS Unplugged project (csunplugged.org) which exposes students to advanced concepts in Computer Science without using computers. Prototype Unplugged activities built in virtual worlds are on a local server as they are designed for the use of primary school children.

Conclusion

Virtual worlds are being used in New Zealand institutions of higher learning. Although Second Life still plays an important role in education, educators are looking into alternatives. The NZVWG is an OpenSim platform that is NZ based and has an academic focus. It operates on servers hosted by Auckland, Otago and Canterbury Universities, and Wellington Polytechnic. NZ educators are using a variety of other virtual worlds and challenging their students to use and create unique 3D interactive environments.

At ascilite2009, Scott Diener from The University of Auckland made the comment that everything in education would change with the use of virtual worlds. "They provide a real sense of self and the suspension of disbelief, a sense of place and sense of emotion." (Diener as cited by Waugh, 2009). These qualities of virtual worlds allow students to become immersed in active, problem-based learning. New Zealand has invested heavily in change with research and practice in virtual world teaching and learning. The evidence is seen in the work discussed in this paper.

The technology and the virtual worlds NZ educators use may change but the one thing that will not change is the commitment of these educators to provide their students with the best learning experiences possible.

CHANGING DEMANDS, changing directions.
Wrest Point | Hobart Tasmania Australia | 4–7 December 2011

Is reflective writing an enigma? Can preparing evidence for an electronic portfolio develop skills for reflective practice?

Bronwyn Hegarty
Otago Polytechnic
Dunedin, New Zealand

Documenting reflective practice would be easier if practitioners were in agreement about the meaning of reflection for practice. Even though evidence exists to support the links between reflection, professional learning and reflective practice, agreement about how to effectively facilitate the reflective process for deeper levels of reflection is not yet established. The reflective writing of postgraduate teacher education students was scaffolded using a Three-Step Reflective Framework. Written reflections were prepared for an electronic design portfolio and assessed by the subject lecturer. All participants demonstrated three levels of reflection in their writing, namely, Descriptive, Explanatory and Supported. There was a degree of critical reflection although this was not directly scaffolded by the framework. All participants found the Reflective Framework useful for assisting them to write reflectively, and the majority intended to carry on using it to assist in constructing a professional portfolio.

Keywords: reflection, professional learning, reflective practice, electronic portfolio, framework

Introduction

The meaning of reflection for practice is not easy to define and has long been debated by a number of scholars. The concept of reflection as a phased process of thinking was initially put forward by Dewey (1933), and later developed into three levels of reflectivity expressed as “ways of knowing with ways of being practical” (van Manen, 1977, p. 205). Generally, the process of reflection is claimed to occur over time so that practitioners can look back on their experiences in order to learn from them (Boud, Keogh & Walker, 1985; Boyd & Fayles, 1983), yet whether reflection occurs as a result of action, during action or for action is an area of disagreement precipitated by Schon (1983, 1987), and further discussed by Hatton and Smith (1995) in their work with teacher education students. This failure to find common ground has implications for practitioners who need to document their professional learning and demonstrate evidence of reflective practice. Even so, evidence demonstrates that clear links exist between reflection, professional learning and reflective practice (Boud et al., 1985; Fook, White & Gardner, 2006; Loughran & Corrigan, 1995; Mansvelder-Longayroux et al., 2007; Moon, 2007; Nsibande, 2007; Valli, 1997). Current thinking confirms that the preparation of written evidence can develop reflective practice, particularly when it is destined for inclusion in a professional portfolio (Doig, Illsley, McLuckie & Parsons, 2006; Levin & Camp, 2002; Mansvelder-Longayroux et al., 2007). However, research investigating the importance of reflective writing for a professional ePortfolio is rare (Hegarty, 2011).

For this research, existing definitions of reflection were explored (specifically, Boud & Walker, 1990; Boud et al., 1985; Rodgers, 2002; Tremmel, 1993) and a definition developed to inform the reflective framework used in the study. Reflection was defined as: deliberate and mindful thinking about one's experiences and the self-evaluation of feelings, decisions, understandings and actions, which may lead to development of professional learning for professional practice. Reflection which demonstrates these attributes is regarded, in this research, as 'effective reflection' and is associated with reflective practice, thus establishing a connection between reflection, professional learning and reflective practice. Also, definitions for professional learning and reflective practice were developed based on others' work (specifically, Hatton & Smith, 1995; Kwakman, 2003; Parsons & Stephenson, 2005). Professional learning is defined as any learning which has relevance to professional practice and occurs when new knowledge and understanding, skills and insights are gained and may lead to the achievement of professional goals. Reflective practice is defined as a process associated with professional learning, which includes effective reflection and the development of metacognition, and leads to decisions for action, learning, achievement of goals and changes to immediate and future practice.

Theoretical Background

According to Boud and Walker (1990) "retrospective noticing", can initiate the reflective process, but requires attention to inner thoughts and feelings if ingrained assumptions and potential learning are to be unlocked and other perspectives considered (p. 71). Similarly, Robert Tremmel's work demonstrates the importance of encouraging teacher education students to pay attention, and through noticing their thoughts and feelings, they can be guided to 'see' the detail of a situation (1993). Rodgers' Reflective Cycle contains a similar message, for example: "Presence in experience: Learning to see" (2002), and she claims that noticing initiates the reflective process leading to meaning being uncovered and an appropriate response. Boud and colleagues (1985) in their model of reflection, describe the first two stages of noticing as "Returning to the experience", and "Attending to feelings", and believe that this engagement prompts practitioners to act and change practice (p. 26). A third stage, called: "Re-evaluating experience", is transformative because actions and thoughts emerge as a result of working with new forms of knowledge in light of existing knowledge (Boud et al., 1985). Likewise, 'Learning to take intelligent action' is described in Rodger's (2002) reflective cycle. These theories provided guidance for developing the definition of reflection for this study. In turn, the definition of reflection provided a foundation for the framework used to scaffold the reflective writing process. The framework incorporates three steps: noticing, analysing and taking action.

Scaffolding reflection is commonly regarded as essential to success (Donaghy & Morss, 2000; Sparks-Langer et al., 1990). For example, according to Bean and Stevens (2002), "scaffolding helps to focus students' reflections and provides explicit support in modeling the role of reflection" (p. 216). From Maarof's (2007) perspective "explicit training or development of skills to assist … in reflecting upon their practice" is recommended (p. 215). Also, if practitioners are to extend their skills and examine their experiences using techniques beyond superficial description, support for reflective writing is regarded as essential (Hatton & Smith, 1995). In a study with 60 teacher education students, Hatton and Smith (1995) identified specific evidence of reflection in their writing about practice experiences, and this led to the development of a reflective framework for subsequent use, both for structuring reflective writing at a deeper level, and in the measurement of reflection for practice (see Table). Furthermore, five phases of cyclical reflection were used by Korthagen and Vasalos (2005) to assist student teachers to learn from their experiences, and they described this as the ALACT-model of reflection. (a) action, (b) looking back on the action, (c) awareness of essential aspects, (d) creating alternative methods of action, and (e) trial (Korthagen, 1985, p. 12). This cycle assisted the student teachers to develop their skills of reflection bringing them to a stage where they demonstrated “core reflection” with more awareness of themselves as practitioners, and able to critically analyse problem situations (Korthagen & Vasalos, 2005, p. 55). The structured approaches used by Korthagen and Vasalos (2005) and Hatton and Smith (1995) are intended to enhance both reflection and learning for professional practice as teachers can be taught how to reflect in preparation for reflective practice. This was also the intent of using a framework in this research study.

Rationale and context

An intervention was needed in a post-graduate teacher education subject where the lecturer found it challenging to get students to reflect at a level necessary for meaningful learning. She was interested in finding a solution for students in her post-graduate teacher education classes who generally wrote little more than superficial accounts when asked to reflect about their experiences. The students were required to prepare reflections about the process of designing multimedia learning objects for inclusion in an electronic Design portfolio. The subject lecturer believed it was necessary that professionals developed skills for reflective practice, yet in previous classes unstructured processes for reflective writing had not been successful. Therefore, an investigation into the use of a reflective framework to scaffold reflective writing was needed for students. Given their educational and discipline specific context an electronic portfolio was used to document their work and provided the context for this research.

Framework and research questions

When choosing models on which to base the framework for this research, specific attributes were sought, and included “their propensity for guiding reflective processes such as noticing, describing the experience, interpreting or analysing the experience, examining other perspectives, and learning from the experience in order to act or make changes to practice” (Hegarty, 2011). Specifically, a guided sequence of reflection within a hierarchal framework was required, thus “starting the beginner with the relatively simplistic or partial technical type [of reflection], then working through different forms of reflection-on-action [including critical reflection] to the desired endpoint of a professional able to undertake reflection-in-action” (Hatton & Smith, 1995, p. 45). The intention was to support practitioners to develop skills for critical reflection as this was regarded by a number of researchers as a desired indicator of reflective practice (Fook & Gardner, 2007). Therefore, a framework using three steps was developed to guide the sequence in which the participants reflected on their experiences. Being sufficiently skilled to recall and record the event effectively is claimed to deepen the reflective process (Boud & Walker, 1990). Use of the framework by the participants was expected to assist this, and also contribute to the development of a professional portfolio which contained evidence of learning and reflective practice.

Portfolios

Portfolios are claimed to give teachers the opportunity to document their “experiences, thoughts, actions and … learning…” (Kilbane & Milman, 2003, p. 565), and as such, assist teachers to reflect on their practice, and communicate their professional learning (Loughran & Corrigan, 1995). Although, reflection and professional learning are claimed manifest during portfolio development (Allan, Zylinski, Temple, Hislop & Gray, 2003; Doig, Illsley, McLuckie & Parsons, 2006; Falls, 2001; Wright, Stallworth & Ray, 2002), research is still unclear about how practitioners make connections between artefacts and evidence and reflect on them (McCoy, 2005). The reason that reflection is believed to be stimulated during the development of a portfolio is because experiences have to be analysed and interpreted in order to create the portfolio (Mansvelder-Longayroux et al.,2007, p. 49), and in this way practitioners are more likely to learn about themselves (Walker, 1985). In this research, the reflective content of written reflection assignments prepared for an ePortfolio and the way in which they used the reflective framework was of interest, not the process of developing the portfolio. The research question discussed in this article is: How do educational practitioners reflect when using a framework to write about their experiences?

Research Methodology

Case study, as a qualitative method using an intervention, was chosen to study how participants responded in a "real-life context", and is an approach based on work by Yin (2003, p. 15). The intervention, the Three-Step Reflective Framework (see Figure 1), was developed for the research study, specifically to scaffold the reflective writing of seven postgraduate teacher education students who were studying in a multimedia design subject. The participants were asked to use the framework when preparing written reflections about their experiences designing multimedia learning objects, all of which were destined for inclusion in an electronic portfolio, and were assessed. Therefore, the case was bounded by the enrolment and assessment requirements of the subject. This research was undertaken as part of a larger study in which diverse data was collected (survey, participant interviews and subject lecturer interview, and written feedback). The detailed findings of the study are not described in this paper (detail about this can be found in Hegarty, 2011). The findings presented in this paper focus solely on the reflective writing produced by participants as a result of using the Reflective Framework.

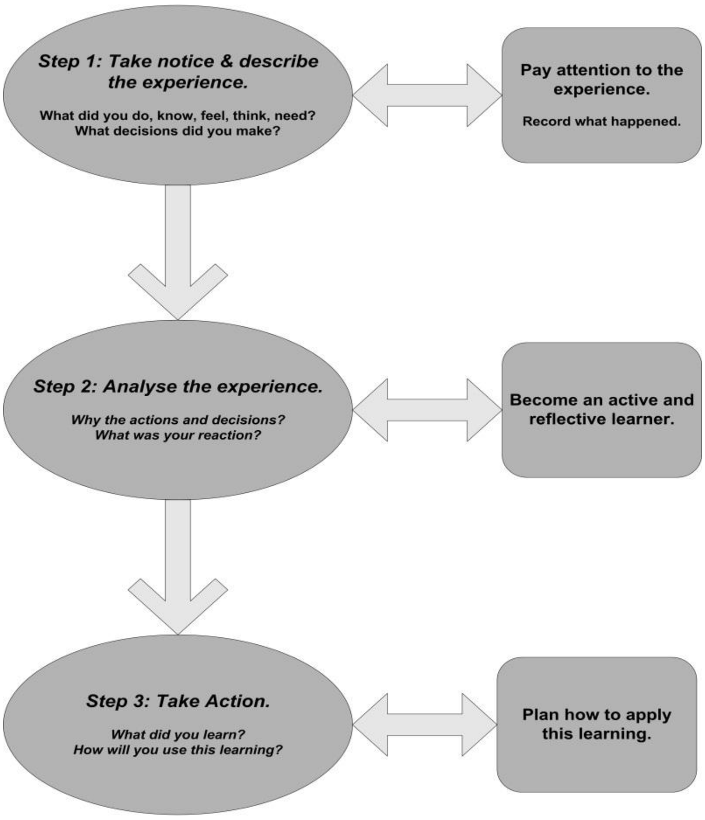

Figure 1: Three-Step Reflective Framework (Hegarty, 2011).

At each of the three steps of the framework, questions were used to guide participants to reflect, and some of these are shown in Figure 1. For example, at Step 1, participants were asked to notice their experiences and describe what happened. Additionally, further questions were used to prompt reflection at each of the three steps, and were available in the template used to structure participants' reflective writing. Use of the framework was optional. Nevertheless, participants were encouraged to use it by the subject lecturer, and introduced to the framework during an on-campus workshop at the start of the subject which was when the research began. At this time, the researcher explained the steps and provided participants with an opportunity to use the framework during exercises in reflective writing.

The participants

The seven participants originated from a variety of educational areas and included teachers, instructional designers, an IT specialist and a staff developer. The commonality amongst the group was their interest in multimedia design for learning, and enrolment in a Masters of Education programme. Participants' area of practice was multimedia design about which they wrote during this research. One participant had extensive previous experience in using reflective writing as part of her practice whereas the others were more familiar with using reflection during verbal debrief sessions with colleagues or when thinking about their practice. Therefore, for the majority of participants, the preparation of written reflective pieces of work about practice was a new challenge.

The subject lecturer regarded reflection as an important skill which teacher education students needed to learn the professional practice. Therefore, the framework provided a practical solution to support this area of practice. There was an expectation that the framework would support participants to develop their skills of reflection which would manifest in how they reflected at each of the three steps, and also in what they focused on in their writing. For example, , it was of interest whether they wrote about their feelings, learning, decisions, goals, professional skills, personal perceptions and others' views. Also, the framework was expected to guide participants to produce evidence of not only their reflective learning, but also their professional learning associated with practice experiences in the multimedia design subject. For the participants their experiences in the subject were not isolated from their professional practice as they were designing learning objects for practical use in their work. Therefore, explicit links to their professional work as well as their professional capability were expected.

Theoretical framework for analysis

To measure the levels and types of reflection in participants' writing a Levels of Reflection taxonomy was developed and used for analysis. This taxonomy is based on Hatton and Smith's (1995) four level framework, and the seven level Framework for Reflective Pedagogical Thinking developed by Sparks-Langer et al. (1990) (shown in Table 1).

Table 1: Comparison of two theoretical frameworks.

Framework for Reflective Pedagogical Thinking - Sparks-Langer et al. (1990, p. 27).	**Criteria for the recognition of evidence for different types of reflective writing (Hatton & Smith, 1995, p. 48).**
1 No descriptive language. 2 Simple lay person description. 3 Events labelled with appropriate terms. 4 Tradition or personal preference as rationale. 5 Principle or theory explained. 6 Context is considered plus principle or theory. 7 Ethical, moral, political issues are included.	1. Descriptive writing - not reflective, description of events. 2. Descriptive reflection- reflective description of an event and justification for actions. 3. Dialogic reflection - demonstrates a "stepping back" and "mulling over" of judgements and viewpoints. 4. Critical reflection - demonstrates awareness about multiple historical and socio-political contexts.

An indepth comparison of the theories underpinning the development of the Reflective Framework is available in Hegarty (2011, Appendix 10). As shown in Table 1, differences between the levels of the taxonomy and the underpinning theories exist at the first level of writing, where an account of events rather than reflection is expected. Conversely, in this research study, practitioners were expected to write reflectively at the first level by describing the feelings and emotions stimulated by their experiences, as this engagement is known to influence the quality of the reflection (Boud et al., 1985). To a lesser extent, work by McCollum (2002) and Rodgers (2002) also informed the taxonomy. By using the taxonomy, five levels of reflection were investigated in each of the participant's four written reflection assignments (28 in total). The levels were categorised as: Descriptive, Explanatory, Supported, Contextual, and Critical, and are listed in brief in Table 2.

Table 2: Levels of Reflection taxonomy, a summary.

Categories and Sub-categories (in italics)	**Description**
1. Descriptive reflection - *Noticing, Deciding, Stating, Self-Questioning, Goals*.	Writing is superficial with descriptions about what has happened and the decisions made but not why.
2. Explanatory reflection – *Personal; Professional; Deciding; Self-Questioning; Reactions; Learning; Stating; Goals.*	Analysis of the experience from a personal or professional perspective about decisions, reactions, learning and goals.
3. Supported reflection –- *Evidence Mentioned; Evidence Identified; Learning from Evidence; Reactions to Evidence*.	Evidence from the literature is mentioned in some way or referenced.
4. Contextual reflection – *Analysis; Cross-Linking; New Perspectives.*	Different perspectives are considered and compared to own views which may change.
5. Critical reflection –- *Application of Learning*.	Multiple perspectives and consideration of wider professional issues, how learning will be used.

During the process of analysis, categories were modified where the characteristics of the content necessitated this. For example, the presence of questions in participants' writing led to a sub-category called *Self-Questioning* being added to the taxonomy at levels 1 and 2. This process of constant comparative analysis enabled an investigation of relationships between categories and the exploration of existing patterns leading to an understanding of the case (Maykut & Morehouse, 1994). Other coding systems were developed to extend interpretative analysis of the data. However, these and the other forms of data which were collected (survey, participant interviews and subject lecturer interview, and written feedback) and the detailed findings of the study are not described in this paper (detail about this can be found in Hegarty, 2011). The findings presented in this paper focus solely on the reflective writing produced by participants as a result of using the Reflective Framework. Changes in the levels of reflection in participants' writing as they wrote were anticipated as they wrote according to each step of the Reflective Framework. To ascertain the quality of reflection in participants' writing, the levels and type of reflection were investigated, and evidence sought of how the framework encouraged professional learning and reflective practice was sought.

Results and Discussion

The findings are reported using pseudonyms for the seven participants. Four out of five levels of reflection - Descriptive, Explanatory, Supported, and Critical – were found in the written reflections (see Figure 2). Contextual reflection, defined in this research as the fourth level of reflection, was not found. Descriptive and Explanatory levels of reflection were found most frequently, and the proportions, measured as percentage frequencies, varied between participants. All participants demonstrated the lower, three levels of reflection – Descriptive, Explanatory, and Supported.

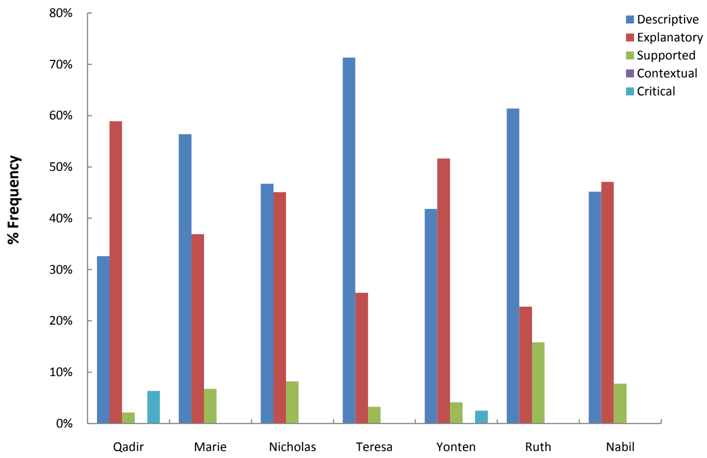

Figure 2: The distribution of five levels of reflection in written reflections (n=7).

This result was anticipated from the research on which the analysis of the levels of reflection was based (i.e., Hatton & Smith, 1995; McCollum, 2002; Rodgers, 2002; Sparks-Langer et al., 1990). Higher levels of reflection were either absent, in the case of Contextual reflection, or found at a low frequency, for example, Critical reflection.

Several different types of reflection were apparent at each level, each varying in frequency. For example, *Noticing* and *Stating* types of reflection were predominant at the Descriptive level of reflection (See Figure 3). *Noticing* was assigned to writing where participants "described their feelings and thoughts about their experiences, providing they did not analyse their experiences" (Hegarty, 2011, p. 156). *Stating*, in contrast,

was found when they described what occurred without providing rationale or emotional responses or references to a particular aspect of practice, for example their decisions and learning. Although, most participants commonly demonstrated *Stating*, not all participants demonstrated *Self-Questioning* which was generally found at a lower frequency than other types of reflection. Three participants (Marie, Teresa and Ruth) consistently used this technique in their writing, not only at the Descriptive level of reflection but also at the Explanatory level, and responded to their self-generated questions in their reflections.

The use of self-questioning is claimed to enable deeper reflection because practitioners who use this technique tend to demonstrate analysis of their experiences, and this may extend to critical reflection (Samuels & Betts, 2007). The participants who generated questions in their reflections during this study did not demonstrate critical reflection, but this may be due to the need to use questions which Fisher (2003) claims specifically prompt critical self-questioning about practice. She demonstrated improvement in the capacity of social sciences students to critically reflect by doing this. Self-questioning is also claimed to be a necessary skill for enhancing the practitioner's ability to learn from experience, and enabling them to act leading to changes in practice (Boud & Walker, 1990). They regard self-questioning as an important part of a practitioner's skill set. The use of questions by participants in their writing was anticipated, and possibly resulted from the guiding questions contained within the structure of the Reflective Framework.

For individuals, the frequency of each level of reflection was variable, and no consistent pattern was apparent across participants. Even though overall, participants wrote primarily at the Descriptive level of reflection (Figure 2), at an individual level, participants wrote, either equally at the Descriptive and Explanatory levels, or more so at another of the levels. For example, Yonten wrote more frequently at the Explanatory level than at the Descriptive level, but also demonstrated Supported and Critical levels of reflection (Figure 2). In contrast, Teresa exhibited mostly Descriptive reflection. The type of reflection exhibited by participants in their written reflections was varied as shown in Figure 3. For example, *Stating* and *Noticing* types of reflection, at the

Descriptive level, were most common. A further type of reflection, *Deciding*, was also found at a high frequency at the Descriptive level of reflection. This type of reflection was also common at the Explanatory level alongside *Stating*.

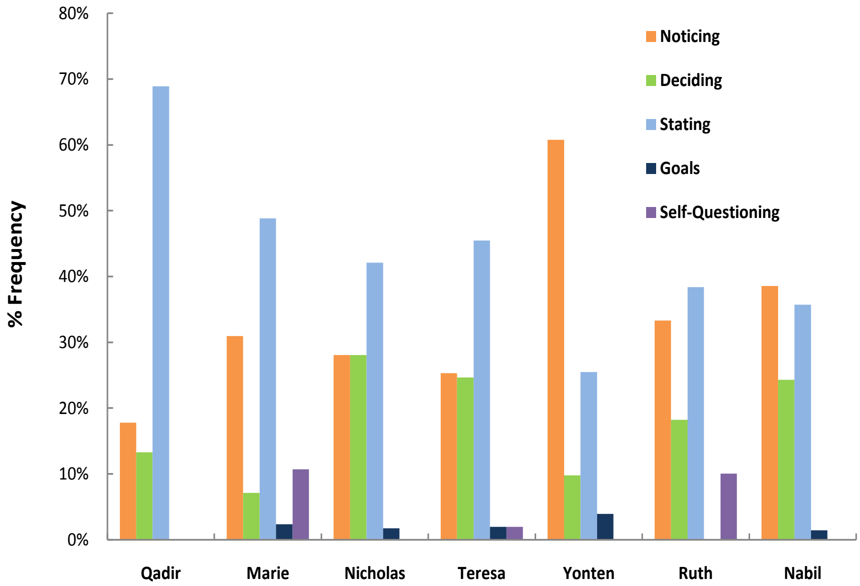

Figure 3: Frequency of Descriptive types of reflection for all participants (n=7).

Goals, although found less frequently than other types of reflection, were evident in all but one participant's writing. Setting goals was an indication that participants were monitoring their learning, and was cognisant with the use of metacognition, claimed to be associated with deeper levels of reflection (Fisher, 2003). *Evidence Identified*, at the Supported level of reflection, was also commonly found in participants' written reflections. This was an indication that they were citing others' work and writing about it in their reflections, although they were not critiquing and analysing multiple perspectives to the extent required for demonstrating Contextual and Critical levels of reflection. Illustrations of these aspects of the research can be seen in Hegarty (2011).

Levels of reflection at each step

The Reflective Framework appeared to encourage Descriptive reflection at Step 1 where it was found at a greater frequency that at the other two steps (see Figure 4). No other level of reflection was particularly evident at any of the three steps. Unexpectedly, Descriptive reflection, in comparison to Explanatory reflection, was also more frequent at Step 2. Links between the headings and prompts in the Reflective Framework and what participants wrote were apparent. For example, *Deciding* was found more frequently at Step 1 and at Step 2, compared to Step 3 where it was not prompted. Also, references to *Learning* were found most frequently at Step 3, and also at Step 2 where it was guided by the framework. Unusually, it was also found at Step 1 where it was not prompted. Critical reflection was found at a slightly higher frequency at Step 2 but was low at Step 3, even though participants were expected to critique their learning and actions with a view to acting on them at this step.

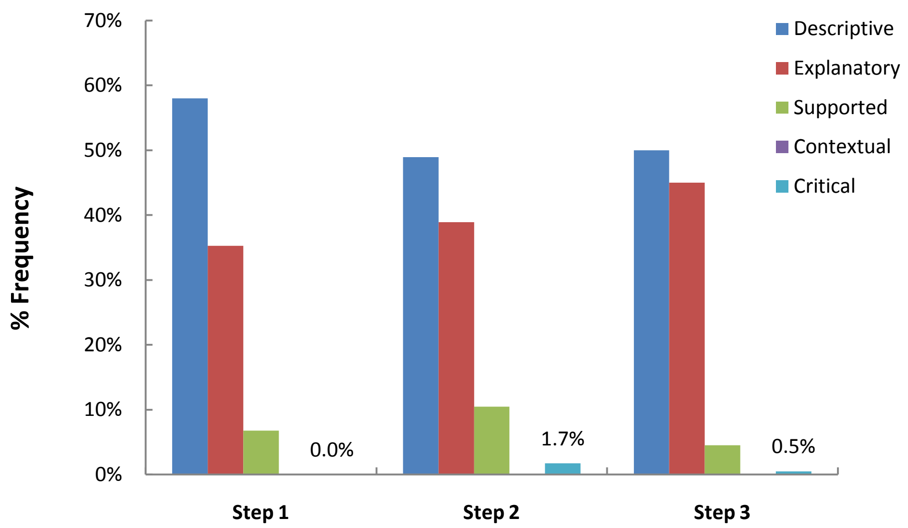

Figure 4: Levels of reflection at each step in the Reflective Framework (n=7).

Although, all participants used the framework to some degree in their written reflections, only two (Yonten and Nicholas) used it consistently for all four reflections. Evidence for this was provided by their use of the framework headings for each step. Although, use of the Reflective Framework varied, all participants found it helpful for guiding reflective writing, and the majority had plans to use the framework in the future to support reflective practice. Therefore, participants demonstrated levels of reflection beyond superficial description, and the framework was a useful tool for scaffolding reflective writing for professional learning and reflective practice.

When the content of the written reflections was analysed for evidence of professional learning and reflective practice, four themes became apparent: *professional capability*, *professional learning*, *professional practice*, and *professional context*. Five participants also demonstrated a connection between their reflections and learning in the multimedia design subject and their actions in practice which was indicative of professional learning and reflective practice. This evidence supported the types of reflection associated with learning and professional practice gleaned from analysis using the Levels of Reflection taxonomy.

Quality of reflection

The quality of reflection in participants' writing was not only indicated by the level and type of reflection but also the propensity of participants to use reflection for professional learning and reflective practice, and to generate questions during the reflective process. It was also apparent that participants considered others' perspectives in their writing as demonstrated by the degree of Supported reflection found. They also exhibited the expression of emotion and included their feelings when writing about experiences. This disposition is regarded as necessary if practitioners are to fully engage with their experiences (Boud et al., 1985)

However, participants did not critique multiple perspectives and compare them with their viewpoints and assumptions, a quality associated with both Contextual and Critical reflection in this study, and critical reflection in others' research (e.g., Fisher, 2003; Hatton & Smith; Ward & McCotter, 2004). For some researchers, reflective practice must include critical reflection as this is regarded necessary for transforming practice (Fook & Gardner, 2007; Minott, 2008). Even so, the capacity to monitor learning through setting goals and reflecting on what was learned (metacognition) was demonstrated by participants in the study and is claimed to be a necessary attribute for supporting reflective practice (Livingston, 1997; McAlpine & Weston, 2000, Parsons & Stephenson, 2005). It appears that participants were engaging in reflective practice, along with self-questioning which has been found to encourage reflection on practice (e.g., Borrell-Carrió & Epstein, 2004; Lemon, 2007; Samuels & Betts, 2007). Evidence of metacognition and the ability to express emotions was also apparent. Such dispositions appear to be linked to effective reflection associated with reflective practice. Engagement in reflective writing using the Reflective Framework may have been influential in changing participants' attitudes to reflection as well as developing their capacity for reflective practice. However, any connection between previous experience with reflection and the quality of the participants' reflective writing was not apparent. However, a shift in attitudes about reflection was evident.

On entry to the research, participants' previous experiences with reflective writing for professional learning and practice differed as did their views about reflection. The majority found writing the first reflection assignment challenging, and believed this arose from a "lack of familiarity with reflective writing and use of reflection as a learning method" (Hegarty, 2011, p. 196)). For Marie, writing her thoughts was threatening, yet she responded positively to the guidelines provided by the framework in scaffolding her writing, and found the process easier with practice. For example:

> Having to writing something down diary style was really confronting and I certainly didn't think I could do it and the guidelines … were helpful and … the reflections became more of a scaffolding ... for me (Marie, interview).

Yonten also found the Reflective framework helpful even though he initially found writing the reflections intimidating. Eventually, he shared the framework with colleagues in another subject because their unfamiliarity with reflection meant they were struggling to prepare written reflections. A contrasting view was expressed by Ruth who claimed that using the prompts in the framework took more time than her own previously established methods as she felt obliged to respond to each of the questions. Although, Ruth had previous experience in reflective writing most of her writing was at a descriptive level of reflection. Although, the majority of participants changed their opinions as a result of using the framework, and were able to see the value of reflection for learning and practice, Teresa's stance did not alter. For example:

> I found it … personally a bit of an awkward way to reflect …. I had to remember what I reflected on and put it in writing all the time, and I found it a more difficult way to reflect in a way, because I had to present things in such detail that [the lecturer] would understand" (Teresa, interview).

It is worth noting that Teresa had originally only used reflection as a way to 'think in her head' and this was the first time she had needed to reflect in writing. Five of the participants intended to continue to use the framework as a professional tool to support their reflective practice, and two of them intended to develop professional portfolios in the form of blogs. Following this research, the Three-Step Framework has been modified for use in guiding teaching staff to prepare blogs for reflective practice. As a result of the research, more emphasis has been placed on prompting the process of considering multiple perspectives and reflecting critically about incidents in practice. The impact of assessing the written reflections was not examined in this research. However, it is an important area as assessment is considered to be an inhibiting factor in the reflective process, particularly when used for reflective practice (Boud & Walker, 1998; Moon, 2004; Pedro, 2005; Stevens & Cooper, 2009).

Conclusion

Writing for reflective practice was scaffolded through the use of a Three-Step Reflective Framework developed for the study. The quality of reflective writing in this research was found to be linked to the levels and types of reflection. Three levels of reflection were commonly demonstrated in participants' reflective writing (Descriptive, Explanatory and Supported), yet critical reflection was rare. Participants commonly demonstrated a type of reflection defined as *Noticing* which indicated they were mindful of their experiences and able to write about their feelings, thoughts and knowledge, demonstrating they were engaging reflectively with their practice.

They also wrote frequently about their decisions and professional skills. The use of reflection for professional learning and self-questioning and references to learning and goals and other viewpoints were further indicators that participants were making use of a reflective process to make meaning of their practice experiences. Therefore, participants were able to develop skills for reflective practice through using the Three-Step Reflective framework. Also, particular dispositions emerged which were associated with engagement in reflective practice. The Reflective Framework was found useful in scaffolding reflective writing for an electronic design portfolio, and continues to be used in other capacities for supporting learning and reflective practice.

Using design principles to improve pedagogical practice and promote student engagement

Jan Herrington
School of Education
Murdoch University

Thomas C Reeves
Professor Emeritus, Department of Educational Psychology and Instructional Technology
University of Georgia

Design principles are fundamental to the conduct of *educational design research* (or *design-based research*) studies, a research approach that is becoming more widely used in educational technology research and pedagogy. In this paper, we argue that design principles can be used to guide the design and development of learning environments in higher education that are based on sound practical and theoretical principles, and that can promote student engagement through innovative learning tasks. We review the use of design principles in educational research, and describe how these principles can be used to design and refine educational innovation and technology-based learning initiatives. The paper describes four phases of design-based research, together with examples of how existing principles can be analysed and used by teachers to inform the creation and dissemination of innovative solutions to educational problems.

Keywords: design-based research, student engagement, technology-based learning, instructional design

Introduction

In addition to the substantial challenges facing the higher education sector generally, such as global competition, socioeconomic access, the increasing need for highly skilled workers, an aging workforce, and rural and remote disadvantage (Bradley, Noonan, Nugent, & Scales, 2008), universities also face significant challenges in adopting and accommodating new technologies in their teaching and learning programs. The *2011 Horizon Report* (Johnson, Smith, Willis, Levine, & Haywood, 2011) noted that, in addition to world-wide challenges to accommodate new digital literacies and new forms of authoring (such as blogs, wikis, networked presentations. etc.) in all disciplines, individual organisational constraints are likely to be the most important factors in decisions to adopt new technologies. The report noted:

> Keeping pace with the rapid proliferation of information, software tools, and devices is challenging for students and teachers alike. New developments in technology are exciting and their potential for improving quality of life is enticing, but it can be overwhelming to attempt to keep up with even a few of the many new tools that are released. User-created content is exploding. (p. 8)

In the light of such challenges, and the need to adequately prepare students for new digital literacies, much attention has been paid to researching and implementing the means to support and improve student engagement. The area is, however, as argued by Bryson and Hand (2007), 'beset by its own complexity' (p. 351). They maintain that opportunities to improve student engagement are possible, at the course design level, through clearer curricular articulation, more attention to implementation, and strong alignment between outcomes and delivery. Others, such as Dickey (2005) argue that educators can learn much about student engagement from the design of games that present students with challenging tasks, role playing opportunities, affirmation of performance, and choice. Such recommendations for design effectively constitute design principles that enable teachers and instructional designers to use well-researched ideas as guidelines for their own efforts to enhance student engagement and learning outcomes.

The education literature is replete with design principles, although they might not always be called that. For example, the following lists from seminal works are forms of design principles because they give heuristics and guidelines for designing for particular outcomes:

Example: Bransford, Vye, Kinzer and Risko (1990) proposed that anchored instructional activities were characterised by the following design criteria:

- A single complex problem should be investigated by the students.
- Students identify and define their own questions.
- Students must have the opportunity to experience the problem from a number of different perspectives.
- Students work on the problem over a 'reasonably long period of time', that is weeks rather than days.
- Activities are logically related to the problem.

Example: Boud and Knights (1996) proposed that the following are important in introducing and establishing a productive climate for reflection:

- Articulating an educational rationale for the process
- Introducing a simple exercise to illustrate reflection
- Providing an opportunity for students to clarify their understanding of the idea
- Introducing a framework or model to aid thinking about elements of reflection
- Modelling a reflective approach in one's own presentation of the idea
- Identifying areas of the process that students can make their own
- Providing time
- Treating reflection as a normal activity.

Example: Oliver (2000) proposed guidelines for the design and development of web-based materials using new technologies:

- Choose meaningful contexts for the learning
- Choose the learning activities ahead of the content
- Choose open-ended and ill-structured tasks
- Make the resources plentiful
- Provide supports for the learning
- Use authentic assessment activities.

Example: McLoughlin and Oliver (2000) proposed ten design principles for culturally inclusive instructional design:

- Adopt an epistemology that is consistent with, and supportive of constructivist learning and multiple perspectives
- Design authentic learning activities
- Create flexible tasks and tools for knowledge sharing
- Ensure different forms of support, within and outside the community
- Establish flexible and responsive student roles and responsibilities

- Provide communication tools and social interaction for learners to co-construct knowledge
- Create tasks for self direction, ownership and collaboration
- Ensure flexible tutoring and mentoring roles that are responsive to learner needs
- Create access to varied resources to ensure multiple perspectives
- Provide flexibility in learning goals, outcomes and modes of assessment.

It is clear that such principles are useful for teachers wishing to implement improvements in their learning environments and pedagogical practice, and they exist in a range of different contexts. Van den Akker (1999) described design principles in more detail as heuristic statements in a format best illustrated as:

> If you want to design intervention X [for the purpose/function Y in context Z], then you are best advised to give that intervention the characteristics A, B, and C [substantive emphasis], and to do that via procedures K, L, and M [procedural emphasis], because of arguments P, Q, and R'. (p. 9)

Such design principles are not 'recipes for success' but are used principally 'to help others select and apply the most appropriate substantive and procedural knowledge for specific design and development tasks in their own settings' (McKenney, Nieveen, & van den Akker, 2006, p. 73).

The identification, application, testing, and refinement of design principles are infused throughout the phases of design-based research, as described in the next section.

Design principles in design-based research and evaluation

The ongoing use and development of design principles is a key defining element of design-based research (also known as *educational design research*, *design experiments*, *formative research* and *development research*) (van den Akker, Gravemeijer, McKenney, & Nieveen, 2006). At every stage of the research process, initial and evolving design principles inform and guide the direction and shape of innovation being developed as well as its implementation and testing, until ultimately, the evolution of draft guidelines into refined design principles become a critical product of the research.

The Design-based Research Collective (2003) suggested four areas where design-based research showed much promise in improving educational practice:

(a) exploring possibilities for creating novel learning and teaching environments,
(b) developing theories of learning and instruction that are contextually based,
(c) advancing and consolidating design knowledge, and
(d) increasing our capacity for educational innovation (2003, p. 8)

In this section, we review the phases of design-based research (as portrayed by Reeves, 2006 in Figure 1 below), and how design principles evolve throughout such research, culminating in sharable design principles that can guide teachers facing problems in similar or parallel pedagogical contexts.

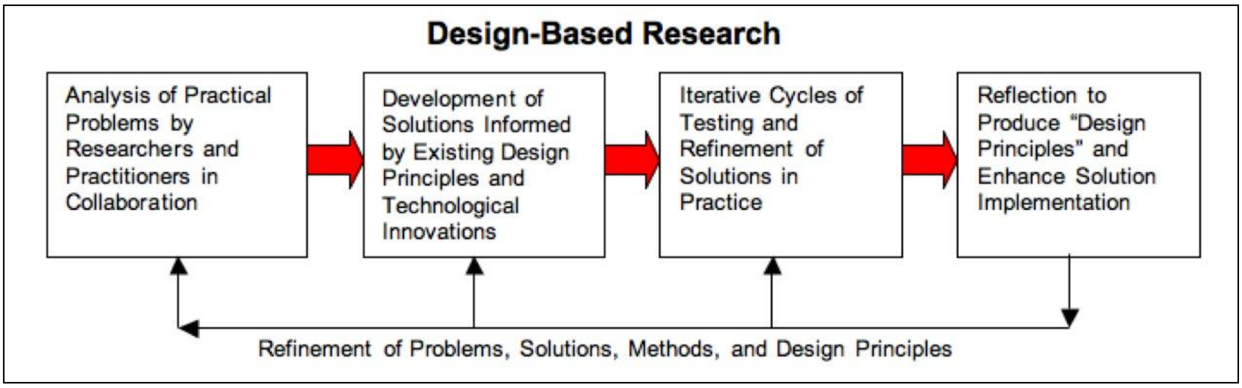

Figure 1: Design-based research (Reeves, 2006, p. 59)

PHASE 1. Analysis and exploration of a problem

In the analysis and exploration phase of design-based research, the problem under investigation is explored in an organic way by the researchers, practitioners and other stakeholders collaborating in the design research initiative. In other words, the problem is explored intensively, not solely from an academic perspective, but in the first instance, from the perspective of the people who deal with the problem on a day-to-day basis. As noted by McKenney, et al., (2006), it is only recently that practitioners have been consulted in early phases of research, whereas previously it might have been more common to consult them, for example, only at the formative evaluation phase.

In design-based research, teachers and researchers collaboratively explore the nature of an educational issue or problem facing students, and work together to create a solution (Design-Based Research Collective, 2003). It is important for teachers to be involved in this phase so that the full extent of the problem is known, rather than being interpreted solely by researchers. However, there is another key advantage to this close collaboration on the exploration of the problem—one that relates to the everyday experience of practitioners and the intimate understanding they frequently have with the problem and its potential solution.

The comparison of the everyday understanding and practice of practitioners and those of so-called 'just plain folk' has been noted by Lave and others (cf. Brown, Collins, & Duguid, 1989; Lave & Wenger, 1991). The issues faced by 'just plain folk' are generally more readily resolved by working with the resources available—those that exist within the context that produced the problem itself—rather than by reference to theoretical guidelines or algorithms. Practitioners, with their intimate knowledge of problems and their contexts and contingencies, can work with researchers to craft solutions appropriate to the context. As Brown et al. (1989) noted: 'The problem, the solution, and the cognition involved in getting between the two cannot be isolated from the context in which they are embedded' (p. 36). Consultation with practitioners who are familiar with the problem area of the research can provide rich insights into complexities inherent in a significant educational problem, because these insights are based upon their intimate and practical understanding of the issues. Practitioners may have developed their own heuristics for solving some aspects of the problem or at least coping with it. These heuristics can form the basis of draft design principles that may be used to guide the design of a solution created in the design and construction phase (i.e., Phase 2 in shown in Figure 1).

Consultations with practitioners are not always formal, and can take a variety of forms to produce different types of valuable data, such as:

- *Participant observation and conversation*: Participant observation by immersion in the setting provides an excellent opportunity to observe first hand the setting and the 'cognition involved' in exploring the parameters of the problem.
- *Interviews*: Deliberately targeting experienced practitioners for interview, together with novice professionals and students, will provide much information on the meaning that practitioners and other stakeholders hold for the everyday activities and issues that relate to the problem area.
- *Focus groups interviews*: The strength of a focus group is that ideas can be bounced off other participants, often resulting in a more robust understanding of the issues, together with potential solutions and ideas for the design of the intervention.
- *Reflective journals or blogs*: Having the agreement of 2-3 teachers who are willing to commit to this reflective recording will provide an invaluable means to explore the problem area first hand.
- *Other types of data collection* can also be used in this consultation process, but written questionnaires and surveys (even those using open-ended questions) should be avoided, as they are less likely to provide the type of in-depth reflective data that is required to fully benefit from the experiences of practitioners.

The data collected from consultations with practitioners can be analysed for themes and issues, and importantly to determine whether any practice-based advice or heuristics can be obtained to inform the design of the intervention. Such ideas can form the basis of draft principles for use in the design phase of the research.

PHASE 2. Development of solutions using existing design principles and technological innovations

The second phase of educational design-based research focuses on a solution to the problem that can be implemented in the educational setting, such as a classroom or online learning environment. While a general literature review is conducted in the first phase to inform the exploration of the problem, in this second phase the literature is again searched to find relevant theory that can guide critical and creative thinking, as well as existing design principles that may have addressed a similar or parallel problem. These principles (similar to the examples given earlier) inform the design of the learning solution or intervention that will potentially provide a solution to the problem.

Creation of draft principles to guide the design of an intervention takes careful thought and analysis because of the need to consider relevant learning theories together with existing principles, as well as ideas from the practitioners. As suggested by van den Akker (1999), using a stem (such as *[Condition x] may best be facilitated by learning environments that*:) will help to keep the principles quite specific and naturally prompt each to start with a verb (e.g., *allow, provide opportunities for, promote, enable, support*, etc.), which ensures that each principle can be related to an action or activity in the learning situation. Once the draft principles have been created, the proposed solution is designed and developed, according to the draft principles (Joseph, 2004). The design and development of the intervention will also be informed by evaluations conducted throughout planning and development, in particular, through needs assessments that inform design, and through formative evaluations that inform development (Reeves & Hedberg, 2003).

By the end of this process, draft principles will have been created from review of theory and research literature, from consultations with practitioners, and from previous research (such as a pilot study), and they will have guided the design and development of an intervention to address a significant educational problem.

PHASE 3. Implementation and evaluation in iterative cycles

The implementation and evaluation cycles of a mature product provide further opportunities to refine design principles. After the first full implementation of the solution with the target group of students and the analysis of the data, the learning environment is refined and then implemented again, in 'continuous cycles of design, enactment, analysis, and redesign' (Design-Based Research Collective, 2003, p. 5). At this stage, further reflection is also recommended for the guiding design principles themselves, and sometimes it is necessary to edit and refine them after analysis of initial findings.

PHASE 4. Reflection to produce design principles

Once a learning environment or intervention has been implemented, evaluated and refined in cycles, design principles can be 'captured' to comprise the sharable, published output from the research in order to inform future development and implementation decisions. This is done in iterative cycles of improvement that are not concluded until 'satisfactory outcomes have been reached by all concerned' (Reeves, 2006, p. 59). Design principles can be further refined by sharing them with other researchers and practitioners, through presentations and publications. Peer review of design principles is essential for the overall enhancement of professional practice to eventually yield improved educational outcomes, such as increased student engagement.

Using design principles to guide educational practice

It is unwise to consider design principles to be 'set in stone'. Instead, they are best regarded as informed reusable guidelines for others wishing to create their own solutions to educational problems across sectors. To further the idea of reusability, Collins, Joseph, and Bielaczyc (2004) aspired to the sharing of design principles across the wider community of educators:

> Our approach to design research requires much more effort than any one human can carry out … it will take teams of researchers and accessible archives documenting design experiments … to make these dreams at all possible. (p. 33)

At least one group has taken up this challenge in the form of the *Design Principles Database* (Kali, 2008; Kali & Linn, n.d.), developed and maintained by the Technology Enhanced Learning in Science (TELS) group. The web-based database contains hundreds of design principles, searchable by subject, audience and category. The database is intended to assist researchers to connect with others working in the same areas 'enabling designers to build on the successes and failures of others rather than reinventing solutions that others have struggled to develop' (Kali & Linn, n.d., para 1). The generation of principles specific to the conduct of design-based research has also been promoted by Ma and Harmon (2009) who argue that because of 'unresolved methodological issues' researchers can also contribute to understanding of the approach by also 'reflecting on their methodology to generate principles on how to conduct design-based research' (p. 86). Some researchers have already contributed to this understanding, such Markauskaite and Reimann (2008) who have explored the potential of e-research to solve challenges of scaling design-based research findings.

Because of its iterative and consultative nature, design-based research is unlikely to engender researcher-imposed directives on how problems should be approached, or in the words of Anderson (2006) 'those types of research that unilaterally descend for testing in a classroom and then disappear with the researcher once the experiment has been concluded' (Anderson, 2005). Reeves (2006) also cautioned against the notion of researchers mandating procedures and processes for teachers to implement: 'Our goal should not be to develop esoteric theoretical knowledge that we think practitioners should apply' (p. 61). However, when presented in the form of design principles, research findings have the potential to effectively bridge the gap between educational theory and practice (Wang & Hannafin, 2005).

Conclusion

In an educational technology class entitled *Learning Sciences*, Park, Choi, and Hong (2010) employed the use of story telling as instructional elements in higher education. Small groups of students selected existing fairy stories or cartoons as analogies to instructional and research approaches. In their presentation of this paper, Park, Choi and Hong described the investigation of design-based research by a group who chose the analogy of the Coyote and Road Runner cartoons. In the cartoon series, the Coyote tries a variety of complex and repetitive means to catch and eat the Road Runner, methods that 'invariably fail in improbable and spectacular ways' (Wile E. Coyote and Road Runner, n.d.). The lack of carefully considered design principles is characteristic of the failure of the Coyote's methods, the lesson being that design principles could assist him to avoid making the same mistakes over and over again. This very apt analogy can be extended to classroom practices, where new processes (or indeed technologies) are employed without theoretical and pedagogical foundation and are thus doomed to fail in promoting student learning and engagement.

Higher education courses, units and tasks that are based on design principles have a solid foundation in theory and practice. They are based on the ideas of practitioners (many with a wealth of experience and knowledge), on the writings of theorists, and on the findings of researchers. They are implemented and evaluated ideally until almost all the problems have been addressed, so they have significant input from students who have been part of the successively improving iterations, and the teachers who have guided them. Such learning environments have a very good chance of engaging students in meaningful and rewarding learning activities.

Design-based research has the capacity to change the ways that researchers and practitioners together investigate and solve significant educational problems in powerful ways. As noted by Anderson (2006) 'design-based research does not seek for universal solutions but rather for deep understanding of innovations and the factors that effect improvement in local contexts'. Design principles assist not only in the development of these solutions but through dissemination, provide the means to extend the results of research beyond the local context to educators in similar and parallel contexts worldwide.

Leading an evidence-based, multi-stakeholder approach to evaluating the implementation of a new online learning environment: an Australian institutional case study

Dale Holt
Institute of Teaching and Learning
Deakin University

Stuart Palmer
Institute of Teaching and Learning
Deakin University

Mary Dracup
Institute of Teaching and Learning
Deakin University

An Australian institutional case study is presented on the evaluation approach being adopted for the implementation of a new online learning environment. Well conceived and inclusive evaluation is seen as essential for the quality management of online learning environments. The focus is on identifying and reconciling the informational needs of various stakeholder groups in the institution, and developing a plan of action covering the key period of implementation. The significant judgements required to carry out evaluation in a multi-campus environment cannot be under-estimated. This is particularly the case given the more recent move to devolving resources and responsibility for the successful implementation of the environment to faculties in the institution concerned. It calls for a more sophisticated conception and set of practices around distributed leadership, as aided by institutions' teaching and learning centres. A set of strategic recommendations are offered to help with the evaluation task.

Keywords: learning management systems, evaluation, quality management, teaching and learning centres

Introduction

This paper draws on work being undertaken as part of an Australian Learning and Teaching Council (ALTC) project, **Building distributed leadership in designing and implementing a quality management framework for Online Learning Environments (OLEs)**, involving Deakin University, University of South Australia, Macquarie University, RMIT University and University of Southern Queensland. One key aspect of the national project is the investigation of the evidence required to enhance the quality management of OLEs. Therefore, the focus here is on leading an evidence-based, multi-level and multi-stakeholder approach to the evaluation of the implementation of a new online learning environment with particular reference to institutionally approved and supported learning technologies like learning management systems. The paper outlines the importance of, and challenges associated with, undertaking inclusive evaluation taking account of a range of stakeholder information needs. This is required to best manage the quality of online learning environments over time. Such an evaluation is a major undertaking, and is not a straightforward task. It is fundamentally political in nature, requiring the declaration and reconciliation of different needs and interests. The way this challenge has been approached in one Australian university is explored. This is not a case study in the making of best practices. It is a case study on dealing with the realities of undertaking large-scale institutional evaluation of complex teaching and learning systems. The strategic and constructive role that teaching and learning centres can play in this endeavour is highlighted.

Background

In line with international developments, Australian universities have made very large investments in corporate educational technologies to support their commitments to online, open, distance and flexible education. Learning management systems (LMSs) have represented the centrepiece of these institutional investments over the last decade or more. Learning management systems are currently perhaps the most widely used and most expensive educational technology tool (Salinas, 2008), and, like many other learning technology trends before them, have been adopted by higher education institutions almost automatically and uncritically (Reynolds, Treharne & Tripp, 2003). The choice of a particular system is a significant decision-making event shaping institutional approaches to ICT-enabled learning for a considerable period of time, i.e. for most institutions at least five years. Many university leaders have a stake in making and implementing such a choice, ranging across University Senior Executive members, leadership of central teaching, learning, media production and IT groups and through various levels of faculty academic leadership. The latter encompassing such leaders as Associate Deans (Teaching and Learning), Heads of School and program and unit/course coordinators. Almost all staff in a university use and rely on its LMS in enabling student learning.

Many Australian universities have recently reviewed, are reviewing or will soon be reviewing their LMS technologies with a view to making decisions on the next generation of online learning environments and developments. In addition, adjunct specialist applications are often integrated into such systems to provide a one-stop-shop for students and teachers. LMSs, and associated corporately supported e-learning technologies, are seen by universities as ‘mission critical’. Running in parallel with these institutionally-supported developments has been the growing use and importance of externally hosted social media/networking sites. These too are contributing to an enhanced learning experience and require increasingly careful attention.

Having committed to a particular system, what types of data are collected at what levels of the organisation to assure and improve the quality of use, and how is evidence acted upon through the various decision-making structures of the institution? The importance of quality management systems, and their current state of underdevelopment in higher education, is highlighted by Fullan and Scott (2009). Turnaround leadership, they argue, is dependent on the development of such systems, and a greater focus on outcomes and impact (as opposed to inputs). They also observe:

> ...a focus on robust evidence is often not front and center when it comes to making decisions about what most requires improvement and attention in universities, what their key strategic directions should be, or how well their core activities are currently working in practice. ...A university culture characterised by a commitment to continuous evaluation, inquiry, and quality improvement concentrates on using evidence to identify what aspects of its current provision are working well and what most need enhancement (Fullan & Scott, 2009, p.80).

The effective leadership of OLEs is also dependent on such systems with the associated focus on learning and teaching outcomes and impacts, and such systems are nowhere more important than in areas of greatest strategic importance and value to the institution – corporately supported LMSs and associated e-learning technology investments. We concur with Fullan and Scott (2009) that much greater commitment to systematic institutional evidence gathering and use is required in the area of OLE implementations. The Australasian Council on Open, Distance and E-learning (ACODE) has developed benchmarks for e-learning in universities and guidelines for their use (ACODE, 2007). Benchmark 2: Planning for, and quality improvement of the integration of technologies for learning and teaching is particularly relevant. The description of this benchmark, a good practice statement and performance indicators follow:

> **Scoping Statement**: There is a need for institution wide quality assurance processes to ensure the appropriate use of technologies in learning and teaching. This will include planning, implementation, evaluation and feedback loops.

Good Practice Statement:
Institutions support and encourage the appropriate use of technology in learning and teaching through strategic planning processes at all levels of the institution. The focus is continuous improvement through systematic and regular evaluation of implementation strategies and outcomes. Such evaluation will in turn inform future planning.
Performance Indicators:
1. Institution wide processes for quality assurance are in place and in use to integrate technologies in learning and teaching.
2. Institution and Faculty plans are aligned with institution policy for the use of technology in learning and teaching.
3. Operationalisation is planned and evaluated.
4. Planning and quality improvement is resourced.
5. Collaboration for integrating technology in learning and teaching occurs across key functional areas.
6. Evaluation cycles are in place to measure key performance indicators for all key stakeholders.
7. Outcomes are reported to all levels of the institution.
8. Evaluation feedback is integrated in planning for continuous improvement purposes.

It is timely to shed light on how universities, through this institutional case study, are currently conducting planning, implementation, evaluation and feedback loops in the context of the new wave of decision making on OLEs, including social networking developments.

Framing evaluation of OLEs: stakeholder analysis

Institutional surveying of staff and students' perceptions of the value of various functions of the OLE that Deakin University adopted in 2003 was undertaken over a three-year period. From a user perception perspective, this survey data provided indicators for action foci to improve staff and student satisfaction, and also challenged one-size-fits all institutional policy regarding the use and support of OLE systems (Palmer & Holt, 2010). Since the time of this surveying, the OLE at Deakin has expanded beyond merely the LMS to encompass a portfolio of e-learning technologies including a synchronous communications tool, a system for audio-visual recording of presentations for later online distribution via downloading, a set of social software tools, a third-party online service for checking the originality of submitted work, and others. Given both the intervening period and the expansion of the range of technologies now included in the OLE, there is a pressing need to update this information, as well as to establish on-going, systematic monitoring of the OLE (Sharpe, Benfield, Roberts & Francis, 2006). With the changing times, comes a need to evaluate students' perceptions of the value of e-learning technologies in terms of their capacities to support strong student engagement, quality learning experiences and quality learning outcomes (Coates, 2006). To evaluate merely student satisfaction with technical-functional aspects of the OLE now falls short of meeting this need. More fundamentally, as the OLE has expanded from being solely the LMS to encompass a portfolio of e-learning technologies, a key question arises regarding the best ways in which elements from the portfolio of technologies can be organised and combined into learning environments to improve learning (Gibbs & Gosper, 2006).

Parties that have a 'stake' in the evaluation are those who can affect or be affected by its conceptualisation and conduct. Their needs, interests, expectations and circumstances need to be carefully considered. Holt, Rice, Smissen and Bowly (2001) identified the following parties as having a key stake in decision making on learning management systems:

- **University Senior Executive**, strategic competitive considerations
- **Management of administrative support units**, cost-effective service delivery considerations
- **Management of academic support units**, learning resource management and quality of education considerations
- **Faculty academic management/leadership**, faculty-based competitive and marketing considerations
- **Faculty academic and teaching support staff**, discipline- and program-based educational considerations (Holt et al. 2001, p.273).

Added to these parties, in Deakin's most recent OLE decision making and implementation phases, has been the University's commercial software services division, i.e. the developer of a major commercial student information system. This party was allocated the responsibility of overseeing the OLE decision-making process and project managing the implementation of the system. They have been particularly concerned to ensure that certain benefits and associated key performance indicators (KPIs) are being used to evaluate the benefits of the new system in use. The planned benefits and KPIs cover:

Benefit 1: Improved student experience
- KPI: More positive student perception of enhanced learning quality
- KPI: More positive staff perception of enhanced learning quality
- KPI: Increased student satisfaction with use of teaching and learning technologies
- KPI: Maintained student satisfaction with DSO [read new LMS as used with accompanying learning technologies]

Benefit 2: Reduction in online course delivery costs
- KPI: Reduction in staff time required to administer units in [new] DSO
- KPI: Increased ease of use for staff (compared with previous LMS)
- KPI: Reduction in ITSD [Information Technology Services Division] staff time required to support DSO

Benefit 3: More contemporary and flexible learning programs
- KPI: Increased innovations to program delivery via DSO
- KPI: Increased ease of use of online learning tools in DSO

Each of the stakeholders' interests naturally impact the ways in which these stakeholders would evaluate the benefits of any new OLE. Each set of interests carries its own self-evidently declared purpose for the evaluation. The purpose of the OLE evaluation has to be framed in an inclusive and non-biased fashion. In the University's case, through the function of an LMS evaluation working party (of which one of the authors has been a continuous member) established as part of the institution's overall LMS governance structure, the purpose of the evaluation was framed as follows: 'To inform all relevant stakeholders and their leadership on progress in realising the benefits of the new DSO in enabling the achievement of Deakin's flexible education vision, along with providing them with a basis for informed decision making'. The question to be addressed was: 'Does the new Deakin Studies Online (DSO) environment [read new LMS as used with accompanying learning technologies] make a difference to teaching and learning at Deakin University?' If the new DSO environment does make a difference, in what ways, how, when and where are the differences experienced? The key questions were underpinned by a series of more specific questions representing a range of views of the various stakeholder representatives involved in the working party's deliberations:

- Does the new DSO enhance the quality of learning and teaching?
- Does the new DSO enhance the efficiency of learning and teaching?
- Does the new DSO enhance the satisfaction of learning and teaching?
- Does the new DSO enhance accessibility to learning opportunities?
- Does the new DSO enhance the administration and management of learning?
- Does the new DSO impact academic workload (new compared to the old system)?
- Does the new DSO provide opportunities for the advancement of higher education research/scholarship?

While the benefits as outlined above were shared and more or less understood by various stakeholders at the beginning of the process, the evaluation scope was seen to be broader than this specification of purpose (the KPIs, on the other hand, were developed through a separate senior management mechanism and shared later in the working party's deliberations). It was felt that evaluation activities had to give stronger expression to students' and teaching staff members' experiences and wishes to contribute to enhanced system use over time. The deliberations begged still further the question of what was in and out of the scope of the planned evaluation. Was the focus to be on the teaching and learning implementation impacts of the new learning management system, as integrated with other institutionally supported learning technologies, all representing the new DSO environment for the University? Or, was the evaluation merely to focus on the new LMS itself, in isolation from other significant learning technologies? The consensus after extensive deliberation was for the former position to be adopted. While important, the assessment of the technical performance of the new DSO and the relationship with the vendor was not seen to be within the scope of this predominately teaching/learning focused evaluation approach. It was assumed these would be handled separately by the University's IT Division and commercial software services operation, respectively. Such evaluation activity, however, was noted in the overall plan (see Table 1 below).

An evaluation plan for the new DSO

While the DSO evaluation working party gradually worked its way through to an agreement on purpose (i.e. the overarching and subsidiary evaluation questions) and shared understanding on higher level benefits and KPIs, a concrete plan of evaluation activities needed to be determined, along with their timing and responsibility for their carriage. As for timing, the evaluation was seen to be needed over a three-year period from 2011 to 2013. The 2011 evaluation would focus on collecting institutional baseline data on the University's current DSO environment and evaluating initial transitioning to the new LMS through the pilot unit program. The 2012 evaluation focus would be on the complete implementation of the new LMS/DSO across the University, with special focus on the value of the new system's features. The 2013 evaluation focus would be on the integration of the new DSO environment across programs/courses as part of the University's new curriculum reform agenda.

The methods of evaluation to be used would cover:

- Institutional surveying of staff and student perceptions of the importance, satisfaction and use of various functions in the current and new LMS, and accompanying learning technologies
- Usage data extracted from the new system at institutional, faculty and program/course level
- Faculty-based surveying of staff and students involved in the new LMS/DSO pilot unit program
- One-on-one development support for teaching staff involved in the pilot unit program
- Sharing of academic developers' and teachers' experiences of the new system through faculty and University forums
- Interviews and focus groups with key staff involved in integrating the new DSO environment into their programs/courses.

The evaluation outputs would include:

- Institutional reports on staff and student use and value attributed to the new DSO environment
- System usage data reports
- Faculty reports and case studies on the use of the new DSO, including the value of new features
- Presentations at faculty and University forums
- Presentations at external academic conferences and events
- Academic publications.

The nature of evaluation methods to be used and their timing is summarised in Table 1 below. The three-year plan is still a work in progress. It represents a multi-level and multi-domain approach involving the work of various stakeholders located centrally and in faculties, and as spread across the University's distributed multi-campus and multi-city operation. It represents an amalgam of centralised and decentralised activities. The evaluation plan is distributed, along with the leadership and control of resources for its various components. The devolution of significant resources and staffing for supporting the implementation of the new LMS to faculties is a significant departure from previous institutional LMS implementation practices. The locus of LMS implementation control has shifted from the centre to the faculties and is represented in each faculty having its own LMS transition plan and local control over the resources to make it happen. Faculty variations in LMS evaluation and research interests and commitments naturally flow from this devolved implementation model.

Table 1: Institution plan of evaluation foci and activities

Evaluation/research activity	**2011**	**2012**	**2013**
Institutional surveying(teaching and learning centre)	Baseline staff and student data on current OLE	Staff and student data on new OLE	Staff and student data on new OLE
Faculty developmental evaluation (Faculties)	New OLE pilot unit program	New OLE initial roll-out	OLE mainstreaming
Faculty summative evaluation (teaching and learning centre with faculties)	New OLE pilot unit program – interviews with staff and surveying of students	To be determined	Not required
Research on integration of new OLE with curriculum development	NA	To be determined by faculties and teaching/learning centre	To be determined by faculties and teaching/learning centre

OLE technical evaluation (IT Division)	New OLE pilot unit program	Going live across the institution	Monitoring ongoing performance
OLE change management effectiveness (Project management centre)	New OLE pilot unit program	Going live across the institution	Full embedding of new OLE in institution's teaching and learning environment

Evaluation challenges

Work in planning the evaluation has raised a number challenges, which are explored below.

What is the purpose of the evaluation?

The purpose of any new OLE evaluation can be clear, that is, clear to those themselves who have a particular view about the benefits to be had from any new system implementation. The problem is that a wide range of views are in force, held by parties who might wish to draw others towards their points of view based on their sense of importance and authority. There are those who have broader and more limited benefits in mind, those who have interests in some benefits but not others, those who see benefits as realisable sooner rather than later, or who, in fact, require that such benefits are realised sooner than later. Some parties are open to unanticipated benefits (and, indeed, costs), while others are fixed on the defined benefits plan. Limited defined benefits call for limited and closed methods of data collection; more open and expansive views of benefits yet to be imagined call for a greater diversity of methods of both open and closed form. To work through these many and possibly conflicted views is not an easy exercise. We see some central organisational group, like a teaching and learning centre, as being best placed to help facilitate and coordinate some overall institutional plan of action (and the three authors of this paper are all actively contributing to it from the vantage point of being members of such a centre). This role was made more problematic within our institutional context as the evaluation plan was conceived at a time when the Centre was in the midst of major restructure and redirection with debates around what and how much should be in the new Centre and what and how much should be devolved to faculty and how the two would work together. A new Centre, accompanying a new LMS, accompanying a national external Australian Universities Quality Agency (AUQA) audit in the first year of implementation provided a highly volatile environment to plan centrally the evaluation task.

What types of evaluation should be conducted?

There was a general consensus in the University's DSO evaluation working party that baseline data should be collected on staff and students' views on the current LMS/DSO environment in the first year of the implementation plan (see Table 1). This surveying should be repeated in the following two years as parties moved into the new system. Two of the authors of this paper designed, produced and administered the surveys in concert with Senior Executive support. The surveys were modelled on those used over 2004-2005 during the initial implementation of the institution's previous LMS. The University discontinued these surveys when the system was reaching a maturity of use, and relied on two items in its standard unit-based student evaluation surveying to ascertain views on systems reliability and value for learning. The new staff and student surveys were expanded to include other accompanying learning technologies that had been added and integrated with the LMS since its initial implementation. The new surveys retain a focus on the importance and satisfaction of various features offered by the LMS, along with the subsequently added learning technologies supported by the institution. In addition, a new dimension has been added related to frequency of use. This was seen as a proxy measure of student engagement, an agenda popularised in recent years through the advent of the Australasian Survey of Student Engagement (AUSSE), which was also used in our own institution for a period. Student engagement relates to the time and effort devoted to purposively designed tasks, and frequency of use is a helpful measure of how much time students spend using various technology features. The survey for students also covers their perceptions of support for the use of the OLE, and, for staff, the adequacy of professional development and training opportunities in using the OLE to best effect. Both surveys have a question for respondents on how well informed they believe they are about the advent of the new LMS. The institutional surveys have received University ethics committee approval. We recommend that as much as possible all data collection methods go through the rigorous process of independent ethics review to ensure they are technically and ethically sound.

We certainly acknowledge that the surveys are product-centric. Questions of how features and technologies are selected, integrated and used by teaching staff is not central to the staff survey design, unless such information is volunteered through open-ended questions on best aspects of the OLE, and those that need improvement. A parallel argument can be made about the design of the student survey. It is again product-centric. It does not directly examine the student experience of engaging with their overall online learning environment. Ultimately, any type of data collection method will have its limitations. Institutional surveying of the type used in our case directly responds to senior leaders' concerns to find out whether the OLE is well used and well valued, i.e. is there an adequate return on the educational technology investment made by the institution? Senior leadership want and need evidence to at the very least know whether a good decision has been made, and that the new system will stand the institution in good stead over time. Exploring the more nuanced uses of the OLE needs to be considered at faculty, program and discipline levels. This is reflected in Table 1 where added depth of focus will be on those units piloting the new LMS in 2011 through consistent student surveying across all pilot units and depth interviews with the leaders of those units. With the new LMS pilot evaluation, unit chairs were asked, in interview, a range of questions covering how they used the new system, how easy it was to use the system for themselves as teachers and for their students, whether they used it differently to the current system, whether it had helped to enhance the quality of teaching and learning, whether administration and management was easier using the new system, along with identifying elements of the system that might have the biggest impact on enhancing learning, ideas on how it might allow staff to change their teaching over time, improvements that could be made, and any additional support or training that would be beneficial. Students undertaking the pilot units received a survey with closed-ended questions covering ease of access and use of various elements of new system in various modes/places, and open-ended questions covering whether the new system enhanced learning, was more reliable, along with identifying best aspects of the new system, areas needing improvement, ideas on what the new system could do but which it can't do currently, and views on any additional training/support needed to use the system better.

Additional forums are planned to be run to allow a broader range of parties (beyond unit chairs) to share their experiences of being involved in the pilot unit program. These forums will involve senior academic leaders, all those involved in teaching on the pilot units, and central and local faculty support staff. Additionally, faculties are collecting data on the fly in their pilot units to help improve the online learning experience as it is occurring. The longer term impacts of the new LMS on curriculum design and delivery are to be researched, although the exact mechanisms to do this are yet to be determined. The new LMS is being implemented at the beginning of the University's new teaching and learning planning period, and relates to the institution's commitment to undertake wide ranging curriculum review and reform.

Finally, apart from transmission of learning resources and facilitating learning interactions, one of the primary functions claimed for LMSs is the provision of evaluation information (White & Larusson, 2010). Most commercial LMSs have some form of built-in analytic reporting capacity that logs and tracks certain types of user activity, typically including number of logins, duration of logins, access to learning resources, communications and other interactions, completion of learning tasks, etc. (Dawson, Heathcote & Poole, 2010). This recorded 'student tracking' data provides system administrators and educators with potentially valuable information for evaluation of aspects of performance of the LMS (Mazza & Botturi, 2007). For example, tracking data on student use of an online discussion space was combined with other information and used to reveal distinct patterns of usage of the discussion space and which types of student posts were positively associated with desired learning outcomes (Palmer, Holt & Bray, 2008). This will be another layer of data analysis in our own institution's approach.

Who needs to approve evaluation?

This is not a trivial question as large-scale institutional surveying of OLEs usually needs to fit within an annual schedule of surveys of students and staff as approved by the University's Senior Executive (and as organised in our case through the University's Planning Unit which is responsible for all institutional data collection). Surveying of students' and staff members' views about various aspects of the institution's OLE must sit comfortably with an institution's ongoing system of student surveying on units and the perceived quality of their teaching. At Deakin, all coursework units are surveyed each time they are offered over a six-week period from late in the teaching period through until the end of examinations. External student surveying also needs to be taken in account. The surveying landscape can be very crowded and students placed in danger of being over-surveyed thus degrading survey responses. Different surveys running concurrently can be frowned upon. To commit students and staff to a further survey on the OLE, an institution must see its OLE as being strategically very important. It must wholeheartedly commit to the importance of collecting and using institution-wide data for improved decision making and improved practice. More practically, new surveying must be conducted during gap periods in the annual surveying calendar. The surveying, though, must make sense in terms of its timing and use. These logistical matters cannot be under-estimated. The best designed surveying will count for nothing if the surveys themselves can find no room in crowded institutional survey schedules. Enhancing the student experience must be central to the imperative to ask for and secure approval for major new data collection methods. This must be strongly advocated, and Senior Executive sponsorship is essential. The argument will not necessarily sell itself from afar. An added impetus for making such requests and having them seriously considered at the highest level might lie in being actively involved in a relevant nationally funded ALTC-type project where evidence gathering is a major focus of attention.

Who needs to accept responsibility for funding and conducting evaluation?

One might expect that any new systems implementation budget would make allowance for costs involved in carrying out an institutional evaluation plan. Those who manage such budgets can quite reasonably expect an upfront cost estimate. However, providing such upfront estimates is difficult as evaluation planning can be a very fluid exercise, with an agenda that is pushed and pulled between different parties with different information needs, which in turn may be much more or less expansive in nature. Cost estimates can be further complicated by expectations that it is the 'core business' of certain established institutional groups to undertake such work largely from their own resources. These might range from the absolute minimalist stance of using limited currently collected data to opening up whole new lines of rich data collection. Teaching and learning centres can be reasonably asked to make a significant contribution to evaluation activities, but they may not be in a position to run all necessary institutional surveying.

The added challenge in costing and conducting evaluation relates to the devolved nature of the LMS implementation, with faculties being allocated significant amounts of funding to support local developments. Their own transition plans can contain local evaluation commitments and associated funding allocations. This raises the issue of the need to be clear about what is being done centrally and what is being executed locally. It might be reasonably accepted that institutional surveying lies in the province of a teaching and learning centre. Equally, in an environment with strong faculty-based academic development resourcing, it could be reasonably assumed that the lead for research on the alignment of a new OLE with program or discipline curricula might come locally. However, there are activities which fall in-between these two ends of the continuum that can be seen as overlapping and possibly disputed territory amongst stakeholders. This can particularly be the case with planning the evaluation of any piloting of the new system, and in determining what data should be collected consistently across all pilot units and what data should be collected based particular faculties' specific interests.

How long should the evaluation task be sustained?

Our University is planning for special evaluation activities over a three-year period at this stage. Special activity relating to the evaluation of the pilot unit program is only required in the first year of implementation. It has been speculated amongst stakeholders that the benefits of some of the major new features of the system may not materialise in full until well down the track. At a point, special evaluation activity needs to give way to routine and ongoing data collection, which integrates with the institution's continuous quality improvement processes. We see, though, in the longer term, greater opportunities for specialist research projects on various aspects of the impact of the new OLE, particularly with the gradual uptake of significant new features. In the case of our own institution, renewed impetus will be given to both specialist evaluation and research projects through the establishment of a new Teaching and Learning Centre, focused on enabling desired learning futures, and encompassing research, scholarship, development and practice improvement in the realm of flexible education within its mandate.

How can evaluation best inform decision making and improve practice?

Leadership of OLEs is embedded at many levels of the management hierarchy and is exerted informally by leading edge users of any new system. Data collected at different levels for different stakeholders must feed into decision making through myriad structures and mechanisms. Higher level data collection must feed into the institution's OLE governance structure as related to standing committees of Academic Boards and IT planning/budgeting committees. Institutional data showing breakdowns by faculty needs to flow into faculty-based teaching/learning committees and their deliberations (at both faculty and possibly school/departmental levels). More nuanced program and unit data must feed into the leadership of courses, disciplines, units and their teaching teams. The above 'feed in' mechanisms relate to sharing and deliberating on data within vertical discipline-based hierarchies which characterise universities' organisational design (see Mintzberg's (1979) characterisation of universities as 'professional bureaucracies'). The challenge remains as to how to facilitate sharing of experiences and useful practices across faculty, departmental and discipline boundaries; that is, how to promote forms of horizontal leadership and learning. This is where the expertise of leading edge or pioneering academic teachers comes to the fore. In the name of the learning organisation (Senge, 1990), opportunities must be orchestrated to enable such boundary riding. Teaching and learning centres can provide these boundary straddling opportunities through forums, promotion through communities of practice and annual conferences.

The overall evaluation orientation

Educational institutions cannot conduct large-scale controlled experimental research on the utility of different learning management systems, or any other significant educational technology for that matter, for a host of pragmatic and ethical reasons. The practical issues range across the financial, legal and logistical. Few educational technology studies do, in fact, reach purportedly high scientific standards at any rate (see, for example, meta-analysis of online learning studies reported by Means et al., 2009). For example, no university could afford to run in parallel two LMSs to test their comparative utility, nor could they afford to randomly deny an LMS to one student cohort to test its efficacy in relation to those using it in a treatment group, certainly not if the control group constituted distance education students where access and equity considerations apply. Once decisions are made on large-scale enterprise-wide investments in things like LMSs, the institution is involved in long-term contractual commitments. There is no way of easily going back. This applies equally to the human resources that need to be developed over significant periods to reap the best outcomes from any technology deployed. We concur that the best research, scholarship, evidence and experience needs to be applied in educational technology decision making, deployment and use; but all of this is indicative, not definitive, in nature. Professional judgment making must come to the fore.

People cannot be or remain neutral players. Evaluation must have a strong formative, developmental orientation. It must be aimed at getting the very most involved and deriving the very best from what can be obtained from the investments made. Here, we cite the work of Guba and Lincoln (1989) who have explained and critiqued four generations of evaluation. In critiquing the first three generations of evaluation that revolved around measurement, description and judgement, they argue for the need for a new paradigm, 'fourth generation evaluation'. The authors emphasise that evaluation is not about revealing truths. They see evaluation as enabling stakeholder constructions, with negotiation to shared and more sophisticated understandings being the key. Courses of action are, therefore, determined through a process of negotiation between stakeholders, and are responsive to their needs. It is not easy to conduct a fourth generation evaluation as related to OLEs. And yet the spirit of this paradigm is laudable and in some ways desperately required to work through the maze of stakeholder needs and expectations.

Of equal usefulness is the movement around design-based research (DBRC, 2003). The DBRC argues that design-based research has five characteristics.

1. The goals of designing learning environments and theory development are interrelated.
2. Research and development occur "through continuous cycles of design, enactment, analysis and redesign".
3. Design research "must lead to sharable theories that help communicate relevant implications to practitioners and other educational designers".
4. Research must explain the way "designs function in authentic settings".
5. The development of these explanations uses methods "that can document and connect processes of enactment to outcomes of interest". (DBRC, 2003, p. 5.)

DBR sees research and development working in concert through a commitment to ongoing action and evaluation. It seems like a compelling approach to improving teaching practices and learning experiences over time with the advent of new LMSs, and OLEs more generally. The sorts of questions that could be addressed by DBR follow: What forms of online teaching support current pedagogy? What forms of online teaching enhance student learning? Do these differ for different learning areas and fields of study? What are the pedagogical principles on which online teaching is based? Are online offerings equitable? Do online offerings cater for cultural diversity among students? What forms of staff development will best ensure the maximum possible realisation of the pedagogical potential of online teaching and learning? How does online teaching and learning relate to promoting student-centred and lifelong learning?

Conclusion

Many people, both formally and informally, assume and exert leadership on the development of online learning environments in their institutions. They are located across various physical locations and operate in different domains and levels of the management hierarchies. Leadership emerges from the interplay of leaders and hence the focus of attention has increasingly been directed at cultivating distributed leadership to enhance organisational performance. This applies also to orchestrating institution-wide approaches to planning the evaluation of a new learning management system. In order to conceive and execute the best possible evaluation plan for the implementation of a major new institutional online learning environment the following recommendations are offered:

- Active Senior Executive support for the institutional evaluation.
- Clear statement of the benefits to be gained from the implementation of any new OLE.
- Understanding of how identified benefits relate to the needs of major parties/stakeholders throughout the institution.
- Evaluation plan determined for an appropriate period of time, i.e. at least three years.
- Use of an appropriate range of data collection methods which address the key benefit areas, and any associated key performance indicators.
- Clear distinction between evaluation to be conducted to meet institutional information needs and specialised research projects initiated at the local faculty level.
- Timetable for data collection and dissemination of evaluation reports.
- Protocols for the approval and dissemination of completed reports through Senior Executive to inform the practices of early adopters.
- Consideration of evaluation reports through well established governance mechanisms with a focus on required decision making.
- Flexibility where required to focus evaluation efforts on priority areas as they emerge over the implementation period.

Teaching and learning centres have a key leadership role to play in this regard. Centres are in a unique position to see overall institutional developments and needs. However, at least in our own institution, in a time of increasing devolution of academic development resources to faculties, the role must be seen through the lens of distributed leadership. A plan of action must be orchestrated with others and key aspects of it can only happen through the efforts of many throughout the organisation. The paper has attempted to give some insight into the challenges of evaluating the implementation of a new LMS, and how these challenges have been dealt with. Stakeholder interests need to be understood and reconciled in some manageable way. Much is at stake in relation to institutional performance and reputation. Valuable data must be collected and used wisely. Professional judgement making is required in quite a politicised environment. Our own institution’s plan is still in the making and will no doubt have to adapt to changing circumstances.

RMIT University

The poster will present findings from the first year of a two-year nationally funded Australian Learning and Teaching Council (ALTC) project, **Building distributed leadership in designing and implementing a quality management framework for Online Learning Environments** undertaken by Deakin University, Macquarie University, University of South Australia, University of Southern Queensland and RMIT University. The project is running over 2011-2012. This project aims to design and implement a framework that uses a distributed leadership approach for the quality management of Online Learning Environments (OLEs) in Australian higher education. The distributed leadership approach enables the development of the framework and in turn contributes to its implementation. The framework is the vehicle for building leadership capacity. The national project team itself represents a broad range of educational, technical and managerial expertise.

Keywords: quality management, online learning environments, distributed leadership

Project aim

The project aims to: Develop and disseminate through a distributed leadership approach an overall framework for the quality management of online learning environments (OLEs) in Australian higher education. The framework will help guide but not prescribe specific leadership actions in various organisational settings relating to new investments in OLEs, and the ongoing maintenance and enhancement of such environments for the benefit of student learning. It will be a transparent, workable and adaptable set of guidelines, which can also aid internal and external benchmarking of OLEs in the sector.

Key elements of the quality management framework

The poster will highlight the key elements involved in the quality management of OLEs, and their multiple alignments. Specific alignments of particular importance will also be highlighted as based on various investigations undertaken to date. This framework has emerged out of literature reviews, partner institutional profiling and an investigation into learning technologies in use across the sector. The elements of the quality management framework range across **planning, organisational structure, governance, technologies, resourcing and evaluation:**

1. **Planning:** external environmental analysis and trend spotting, strategic intelligence gathering, external benchmarking, organisational capacity analysis, institutional purpose, reputation, vision, principles, objectives and strategies, accountabilities, timelines, and resource implications
2. **Organisational structures:** nature, range, coordination and delivery of valued services (underpinned by clarity of understanding of needed expertise/staffing capabilities) for staff and students
3. **Governance:** institutional, faculty and school/department committees and forums (and associated responsibilities and accountabilities), policies and standards
4. **Technologies:** type, range, integration, promotion, and innovation and mainstreaming of emerging technologies
5. **Resourcing:** maintenance and enhancement of technologies, skills recognition and staff development, media production, evaluation activities, governance mechanisms, i.e. all other elements
6. **Evaluation:** stakeholder's needs, methods, reporting, decision making through governance structures, evaluation relating to the initial selection of new technology, and evidence gathering relating to the on-going assessment of its performance, value and impact.

Certain key element alignments are highlighted: Alignments between Planning/Evaluation/Governance; Alignments between Planning/Organisational Structure; and Alignments between Planning/Technologies. The importance of adopting an evidence-based, multi-stakeholder and strategic approach to evaluating the implementation of online learning environments is highlighted as a key element of the quality management framework and its implementation.

Distributed leadership

There has been significant interest in new lines of leadership theorising around distributed and shared leadership. This theorising sees a paradigm shift from a focus on the leader, as individual, and his or her traits, skills, styles and behaviours in relating to parties designated as followers to a focus on the phenomenon of leadership as enacted through various parties in multiple relationships with leadership intent and capability to achieve valued goals. These parties may be those in formal leadership positions at different levels and in different functional areas in the organisation who wish and need to act in concert, or it may involve those with particular interests and capabilities emerging as informal leaders for periods of time and acting in concert with those with formal leadership authority. Leadership of this nature is seen as distributed or shared (possibly even described as dispersed or networked). While scholars in these fields may take issue, for the purposes of this project, we will treat these terms as being interchangeable and draw upon literature in these domains in covering conceptual and practical matters.

Much of the interest on distributed/shared leadership has emanated from the schools sector at national and international levels (Leithwood, Mascall & Strauss (Eds.), 2009; Harris (Ed.), 2009; Spillane, 2006; Spillane, 2007). As applied to the schools sector, 'the core principle is one of extending or sharing leadership practice' in response to increasingly perceived structural limitations in advancing leadership and organisational performance (Harris, 2009, p.3).

In summing up the extensive literature on distributed leadership emanating from the schools sector, Spillane (2006, p.4) identifies three essential elements in framing a distributed perspective on leadership: Leadership *practice* is the central and anchoring concern; leadership practice is generated in the *interactions* of leaders, followers, and their situation; each element is essential for leadership practice; the *situation* both defines leadership practice and is defined through leadership practice. In relation to this project, distributed leadership is positioned as contributing to clarity of shared understanding of quality management framework elements and constructive alignments amongst them. To achieve this, distributed leadership must be acknowledged in all its forms, developed and be well aligned both vertically and horizontally. The overall responsibility for cultivating distributed leadership resides in senior formal leadership positions within the institution.

Let's talk - providing virtual ESL learning support from a distance

Mareena Ilyas
Learning Support Centre
Manukau Institute of Technology

Oriel Kelly
Institute Academic Projects
Manukau Institute of Technology

This paper describes the results of a pilot undertaken to find how suitable the Wimba virtual classroom option is in providing academic learning support from a central Learning Support Centre for English as Second Language (ESL) students not based on the main campus of the institution. With the increasing number of remote campuses being established there is a need to provide equitable learning support to remote students. While learners had positive perceptions of the virtual classroom's interactions as language learning tools, the pilot study highlighted some complications to the transition to virtual support. A number of lessons were learned and will be shared.

Keywords: virtual classroom, ESL learning support, equity of provision, remote campuses

Introduction

Virtual classrooms and web conferencing have been successfully integrated into higher education for teaching purposes and their effectiveness has been established through sustained research investigations. The suite of tools that these synchronous classrooms provide, according to the literature, allow instructors the interactive elements that today's learners need to succeed in both blended and pure distance learning environments (Kudyma, Aoki, & Liu n.d; Sweeney, 2009; Frutos-Perez, 2009). The virtual classroom "employs a combination of synchronous and asynchronous technologies such as audio, video and other data sharing and interaction tools (e.g., an interactive whiteboard, document sharing, desktop sharing and multimedia discussion forums) to provide an integrated learning environment where multimodal interaction with both human and materials can be facilitated" (Chen & Wang, 2008, p97).

The flexibility in time, convenience of place, (Wu & Hiltz, 2004; Henry & Li, 2005) accessibility and equal opportunity to all learners are the major advantages cited by many researchers who support the use of virtual learning environments (Everett & Ahern, 1994; Lamy & Goodfellow, 1999; Ortega, 1997; Warschauer & Kem, 2000). Their use creates opportunities for those who would otherwise not be able to take part in learning.

However, it appears the virtual classrooms are not well used, especially if a traditional didactic approach is adopted, (Andrews et al 2008), or if the students are confused by the multiple avenues available for interaction (McBrien, Jones & Rui, 2009) or if the controls of the classroom are not given to the students to make use of as well (Ng, 2007). It has been suggested that instructors need training in how to use these classrooms effectively (Barrett, 2010) to transition from face to face to virtual interactions, and clear guidelines on how to structure the sessions appropriately (Pelliccione & Broadley, 2010). If as the literature suggests, teachers are cognisant of the need to adapt their practice and adopt strategies as fundamental as recognising the importance of socialisation and informal exchanges (Finkelstein, 2006), turntaking (Deutschmann & Panichi, 2009) and reducing the transactional distance (or cognitive space between learners and instructors), (Moore 1993) the classrooms are a powerful tool in the teaching and learning process for the programme of study, **and** the provision of academic learning support, particularly to ESL students.

Although the advent of a virtual classroom environment is relatively new, the impact of using such tools in language teaching itself has already been proven (Ward, 2005; Lafford & Lafford 2005). Additionally, learning a language can be an anxious process for many due to second language learners' inhibitions (McIntyre et al., 2003). However, a virtual learning environment has proved to be conducive to language learning as it appears to reduce student self-awareness and social anxiety, which results in increased language production, and the environment has the potential to address various difficulties facing distance language learners (Bradley & Lomicka, 2000; Wallace, 1999; Carnevale, 2003; Roed, 2003).

This paper describes a pilot which was carried out to determine whether the attributes of the virtual classroom were a viable option to meet the **ESL learning support needs** of the diverse student body located at remote campuses, away from the centralized, in-person provision of the institute, and therefore provide a more equitable service to students.

Context

The institute has multiple remote campuses in various areas in addition to the main campus. The Learning Support Centre is situated on the main campus with subject specialists who provide extra academic support to the students. The role of the specialist ESL Learning Advisors at the institution is to give language support to mainly ESL students. These students who need extra academic/language support can access the service in person at the main campus outside their class time, individually or with a group. Lecturers can also refer students to the Learning Advisors when they themselves identify students in need of additional support. Learning Support Centre records clearly show, however, that **remote** campus students rarely access the Centre's services. Reasons usually given by students are that getting transport to the main campus is a barrier, and the time involved is better spent in other ways. Likewise, travel time and scarce resources are the main factors that limit the Learning Advisors themselves from going to the remote campuses more frequently. Facilitating the learning of students via a virtual classroom then was seen as a possible solution to this problem.

Process

A pre-survey established that the students and staff were ready to try the virtual support concept, therefore an appropriate time was negotiated with the lecturers at the remote sites to deliver trial sessions. Topic sentence and paragraph writing skills emerged as a common need amongst the participants. Carefully structured lessons were devised to suit the virtual environment (Pelliccione & Broadley 2010). PowerPoint slides and quizzes were uploaded to the Wimba classroom. Technical issues needed to be dealt with and the Advisor had to master the virtual classroom environment and was given support from the Learning Technology Centre staff to make the transition to virtual Advisor. (Barrett 2010). Care was taken to address each aspect that would reduce the three aspects of "transactional distance" as identified by Moore (1993). Each session utilised the two way audio, one way video and text chat functionality (to **encourage dialogue** about the topic being covered), presentation materials and carefully spaced online quizzes with immediate feedback (**lesson structure**). Sessions were archived so that students could revisit the lesson later (assisting **learner autonomy**) (Moore, ibid). Informal exchanges were encouraged before and during the sessions (Finkelstein 2006). The trial support sessions were arranged at times to suit the class lecturers and most of them attended with their students. Learning Technology Centre staff were on hand to deal with any technical issues both at the main campus and at the remote sites.

A total of 65 students took part in the pilot from various language backgrounds and age range. Each class received only one session. Although the theme of the steps of the writing process was the same for each group, sessions were modified according to the student's levels (upper intermediate to advanced).

Results and Discussion

Analysis of Student Short poll

At the end of each of the Wimba sessions students were asked to complete a short poll while still in the classroom environment to gauge the success of the experience. Questions covered both the content and the process as shown below.

Table 1: Student Poll Results

Question **N=65**	**No, not at all**	**No, not really**	**Yes, a bit**	**Yes, completely**
The lesson was interesting	2%	9%	32%	57%
The lesson helped me understand the topic	2%	2%	52%	46%
I am comfortable using the Wimba classroom	2%	9%	38%	52%
I would like to see more ESL Lessons through Wimba	6%	5%	31%	58%

Unfortunately, given the time constraints, the experience could not be repeated for the students, so the outcomes are based on a single instance in each case. Overall, the poll results show that the majority of the students were positive about their learning experience and would like to see more lessons through the virtual classroom. The range of reactions may well have been influenced by the technical difficulties experienced, the newness of the approach and the diversity of the student group.

Analysis of Lecturer feedback

After the sessions the class lecturers were approached for their overall feedback. All perceived that the introduction of learning support such as this via the Wimba classroom was a positive step and useful to students. They all agreed that participation once in the environment was simple, but some help was needed at the beginning to take students through the access process because although students are fine with general computer use, they need a few pointers for navigating to the site, logging in and finding the classroom itself. There were issues with student microphones; some worked and some didn't. Many students had to rely on the text chat function to communicate during the session which was frustrating. However, overall class lecturer satisfaction with the lesson outweighed the dissatisfaction due to technical difficulties/shortcomings they witnessed.

Learning Advisor's reflections

The provision of support via a virtual classroom offers great promise but also poses significant challenges to both staff and the students. For the Learning Advisors too, the process of delivering a range of virtual classroom sessions requires considerable planning, preparation, forethought and skill, which initially required significant allocations of time. Materials once created can be reused though.

The importance of lecturer buy-in

Lecturer enthusiasm appears to be necessary to overcome student passivity or lack of motivation to embrace this unfamiliar means of getting learning support for students, and it was a challenge getting cooperation from lecturing staff at the remote sites. Lecturers are aware of the need for equity of support but do not routinely promote the Learning Support Centre with or for their students. The virtual classroom option could therefore be a more easily accessible support mechanism which could be promoted more rigorously.

Technical issues

Hardware in the remote computer labs was an issue, even though the set up should be the same as that at the main campus. Frequently audio could not be used on the machines as although headsets with microphones were supplied, the microphone did not work plugged into either the front or the back connection. This did not provide a welcoming environment and although computer savvy students were not thrown, those less familiar with technology were somewhat put off by the delay and non-performance. Additionally there is currently no soundproof area at the base venue (in the Learning Support Centre itself) from which to conduct these virtual classroom sessions. It is hoped that if the trial is extended a more suitable area can be found.

Conclusions and recommendations

The pilot has proved the concept of providing equitable learning support to remote campuses via a virtual classroom. There are great opportunities here that allow flexibility, and with the right conditions, the Learning Support Centre staff can offer assistance on a range of subjects to students no matter where they are.

The following recommendations have been made therefore to ensure the success of such a service and to eliminate the issues identified. **S**upporting remote campuses in this way can be achieved if:

- There are high levels of coordination and collaboration by all parties: IT infrastructure services, the staff development unit, Learning Support Centre staff, faculty administrators and lecturing staff
- Technical access to the online classroom is prioritised
- Teaching staff are encouraged to promote the service through high level sponsorship which stresses the strategic importance of the initiative to utilise virtual the support service
- An on-site, face to face orientation for the lecturers demonstrates the possibilities of remote support and the operation of the virtual classroom
