To enable us to replicate this work online we needed for formalise the learning process and develop evaluation strategies. We have chosen to use a learning environment where we can focus on the themes of relationships and interactions through games, and where both a narrative teaching style and a social constructivist approach to teaching and learning are used. Both respect and are in keeping with Aboriginal pedagogical and knowledge sharing approaches. Understanding relationships is the first priority in teaching Aboriginal culture and narratives is the process used by Aboriginal teachers for sharing their knowledge. The web service will furthermore allow us to enhance the learning by incorporating narratives from Aboriginal students, staff and community members to convey a variety of perspective on Aboriginal knowledge to non-Aboriginal teachers and students.

A narrative teaching style is beneficial for other reasons too. Aboriginal students, staff and communities will get a chance to tell their stories to be presented in a learning context that reflects the knowledge system of the Aboriginal contributors. In fact the teaching of culture would be invalid without Aboriginal contributors translating their experiences into the new context (Ramsey and Walker, 2010). Similar to other work on community narratives (Kutay & Mundine 2010; Daniel et al., 2003; Rodriguez et al., 2010), the project facilitates Aboriginal knowledge sharing in an online environment. The use of narrative content forms has proven to be an effective way to teach non-Aboriginal students (Egan, 1998; Blakesley, 2010 and Andrews et al, 2010) and respect traditional Aboriginal storytelling methods (Bradley, 2010).

As well as sharing many aspects of Aboriginal pedagogical and knowledge sharing approaches, narrative teaching styles have emerged within higher education more generally through questioning whether conventional pedagogies prepare students for real life situations. In this context, narrative pedagogy is a phenomenological pedagogy that focuses on the lived experience. While phenomenology emerges out of sociology, in health related disciplines, such as nursing, narrative pedagogy in the higher education context emerges from listening to shared stories, the sharing of knowledge and lived experience (Diekelmann & Diekelmann, 2009). A narrative pedagogy allows '…for a richer array of listening (interpreting) than that allowed by the usual application and presentation of disciplinary epistemologies' (Diekelmann & Diekelmann, 2009: xv).

Also, the narrative teaching style complements a social constructivist approach, and this research is based on developing teaching and learning platforms where students learn through active formation of their own knowledge rather than by memorising or absorbing ideas from presentations by a single teacher (Vygotsky 1978). This approach suggests learning through experimentation or experiential learning and providing opportunities for students to create their own 'worlds'.

These worlds are being developed in Unity, a game engine and open platform for programming animations and simulated gaming paths. By creating practical scenarios that can be tailored to the student's specific professional interests (such as law, education, social work or health) we enable the broad sharing of the audio resources within a learning environment suitable for use within existing University courses, and so illustrate:

1. The importance of Aboriginal people's experiences in explaining the significance of policies and practices that have impacted on their lives and the inherent cultural differences, thus validating this knowledge.
2. The value of a repository of resources for Aboriginal people to share with non-Aboriginal people on different approaches to culture within communities, and the need for a regular update of the repository.
3. The wide range of issues that exist as cultural variations, and the opportunity provided by the web to provide tools to support course development through linking some of the variations into a learning repository.
4. The need for culturally relevant online resources to include Aboriginal perspectives in online knowledge sharing.

The web services used are similar to YouTube, providing the tools to upload videos for sharing within the learning context, but it also provides a strong context for the material, so that it can be re-used appropriately in game scenarios.

Themes

There are six themes connected to Kinship relationships that are covered in the online workshop. The six themes are sequential allowing the student to move successively from one level of knowledge to the next. The student learns about Moiety first, as it is the foundation of Aboriginal Kinship structures and they progressively move through to learning about Aboriginal Nations and language groups. This also enables students to gain an understanding of the complexities of Kinship relationships and the effect on such a cultural system of removals, forced co-settlement and the enforced use of pidgin English as a common language. The six themes are listed in Table 1 below, with the role-play used to assist in student's experiential learning.

Table 1: Workshop themes and role-plays

Theme	Role Play
1.Welcome and Moiety	Dividing into Moieties and introduce concepts and foundations of Kinship structure.
2.Totem and Relationships	Divide Totem groups and see how Totems are divided between Moieties, plus environmental links and establishment of reciprocal responsibilities.
3. Skin Names	Divide into Skin Names, note generational relations, family connections, structures and marriage rules.
4. Language and Affiliations	Divide into Nations aligned to language groups and note relations within Nations.
5. Lines of Communication	Put down lines to link Nation and language groups and discuss relationships between Nations that affect conservation, survival, religious and Kinship connections.
6. Disconnected Lines	Connection lines are removed. Discuss effect of forced break between Nations, removals, forced co-settlement and use of pidgin English as common language.

The role-plays are short flash videos allowing some interaction from students. They are required to move their icon according to their relationship to others on the screen, and so deals with themes being taught in the online workshop. At present guidance is presented as audio commentary from the original interactive presentation. They allow students to change from the role of observer to one where they are acting within the culture they are learning about in that they are assigned a Moiety, Totem group, Skin Name and a Nation. As the second part of the workshop is developed, more sophisticated games and a variety of narratives will provide a more immersive experience of these themes and concepts.

Levels of learning

The introductory online workshop provides information for the students on how Aboriginal Kinship systems work, and how this affects reciprocal responsibilities and relationships within the cultures. Students are then presented in scenario based games with situations experienced by Aboriginal people after invasion through the narratives, where Kinship systems were ignored and their culture denigrated. Students will then be asked to consider the various effects of European culture and the introduced language on Aboriginal systems and cultures. These scenarios are more highly guided experiences than the research and journal style of role-play discussed in Genat, Naidu and Fong (2008). and are based on the idea of reusable labs developed in Ben-Naim and Prusty (2010).

There are two main methods used in the workshop and scenario designs to provide for immersive learning. The first is to abstract, where the workshop presents Aboriginal views and explains what is being done within the culture to preserve their specific society and the environment in which they live; and presents how this varies from non-Aboriginal culture. For example, ‘Kinship’ is used in all cultures to establish the responsibilities you have for those closest to you. In Aboriginal societies Kinship obligations have to work across Family, Clan and Nation groups spread across Australia. This has led to a complex system of rules, such as restricting marriage to distant relations. In larger societies, such as British, the family obligations are restricted to immediate biological relations and often not linked to marriage rules.

The second is by analogy from known experience, where aspects of culture are selected, and then students are asked how this would affect relations, responsibilities or survival within another cultural context. Two examples of this strategy are to:

1. Imagine you are welcoming someone to your Country or Nation. What would you explain to them so they are aware of the basic rules and obligations within your society?
5. Remember the place you grew up and all its features. Then imagine if your parents, their parents, and so on also lived on the same land, and could tell you how the land changed over millennia of time, the geography of the land and where and how all the animals on this land lived; how to care for the land and its inhabitants; and through this how to respect the Land. What would your connections and relation to the land be?

Out of these two approaches has arisen a third mode of learning, which is primarily done through narratives. This we call the historical context, where a lack of ability by the invaders to ‘walk in the shoes of Aboriginal people’ has led to the imposition of the rules of one culture on another. The aim of the workshop and gaming system is to enable students to understand that this has happened, and the ongoing effects this has on the people who will be their clients and with whom they may work when they graduate as lawyers, social workers, teachers, etc.

We have used the Action Research methodology to develop and evaluate the learning system, both to verify its success in light of the original presentation, and to analyse the benefits or losses from moving the teaching online.

Action Research

While the project involves developing an innovative learning context and tools for teachers, the focus is on how teachers will design the learning sequence for specific learning outcomes (Wills, 2012). The approach taken for this development is Action Research (Kemmis & McTaggart, 1998), being a process that is self-correcting (cyclical); able to adapt to innovative situations (dynamic); and involving all stake holders (collaborative). This approach is also known to incorporate practical action in the pursuit of theoretical understanding in a manner that removes the research from the colonising framework of previous studies (Smith, 1999) and 'opens a space where colleagues were able to create a new community of engagement' (Everett, 2008, p.1).

At the same time we had to consider the appropriateness of IT for Indigenous knowledge sharing. While we place the Indigenous students in the role of peer-teachers, we were encouraged by some previous research into Aboriginal use of IT (Kutay & Ho, 2011; Reedy, 2011) and note the concerns raised by Reedy (2011):

> The students embraced the use of technology and were very interested in developing digital literacy skills to use in the learning environment as well as for work and social purposes. The digital tools used in the project were those which were available, reliable, effective and easy to use. The tools used in the classroom during workshops and subsequently for homework activities were also linked to skills that students indicated themselves that they wanted to develop (p.1063).

Action Research is a complementary methodology that allows us to facilitate a reflective pedagogical project that will lead to educational transformation (Somekh & Zeichner, 2009, p.6). The use of the term action research in this context signifies the collaborative, productive and reforming characteristics of the project. That is, one of the overarching objectives of the project is to contribute to pedagogical reform by engaging a range of stakeholders (Brydon-Miller & Maguire 2009. p.79) in the project development in a way that endeavours to support strategic change in higher education by embedding Aboriginal knowledge in mainstream courses, through web services. Also this research involves different phases of an interactive action-reflection cycle.

The project development and stakeholder engagement is being conducted over three stages. For each stage, there is a cycle or series of steps undertaken to ensure that all stakeholders are actively engaged in the development of resources forming the basis of the web services that provide exploratory learning environments. Details of the completed first and second stage of stakeholder engagement and evaluation are presented below. The third stage of stakeholder engagement and evaluation will be with Aboriginal users uploading narratives and students using the final simulation role-plays.

Stage One

In stage one the project team ran a series of evaluative sessions with non-Aboriginal students and Aboriginal students and communities. The first cycle of evaluation involved non-Aboriginal students engaging with the material content of the interactive workshop and commenting on the ability of the online version to explain Kinship concepts. An evaluation survey was done of the original interactive presentation, which was conducted in 2009. The findings from this feedback are presented later.

In 2011, face-to-face discussions have been held with participants following their participation in a presentation. These sessions were run with both Aboriginal and Non-Aboriginal students who had participated in the face-to-face interactive presentation as part of their course attendance.

Non-Aboriginal students were asked:

- What did you like about the Kinship presentation. What was new to you?
- What was hard to understand?
- What would you like more information on?
- Would you use this understanding in your profession?

- How was this relative to your course work?

The feedback from these sessions was found to focus on enhancing the presentation of the material. As the creator and presenter, Riley used the feedback from these questions to improve the delivery of the material ensuring that students' level of comprehension improved. Since the presenter is Aboriginal, at times she assumes some knowledge and ideas when explaining the concepts to students, so feedback from the surveys and face-to-face discussions has helped refine the presentation. Once the initial presentation was refined, the video material was edited into thematic modules.

The next cycle in this stage involved consultation with Aboriginal community members and students which focused more on suggesting additional material we can use online, to provide further resources and perspectives for students who are using the workshop in their courses. Aboriginal students who were enrolled in years 2-4 of the Bachelor Education Secondary Aboriginal Studies course, which is run in Block Mode through the Koori Centre, University of Sydney, were asked:

- What stories would relate to the Kinship presentation in an on-line version?
- What would need to go onto an on-line presentation?
- What Kinship issues are needed to be mentioned and explored?

From these sessions a series of ideas were gathered and collated under the workshop themes. This material is being collected and linked to the workshop videos as time-selected locations, according to relevancy. For example these sessions were used to expand on the sub-topics to be included under the main themes and has been published (Kutay et al. 2012). This expanded table will be further developed to provide the topics to collate narratives added to the workshop.

Through this process, Aboriginal students who will be future Aboriginal Studies teachers are involved in knowledge transmission, and non-Aboriginal students who may work with Aboriginal clients and colleagues are involved in shaping the material content of what they learn and what knowledge gaps exist. This has important pedagogical implications for providing student-centred learning, which involves students being consulted about their learning. In this context, students are agents in the development of their own knowledge resources (Stenhouse 1978) and the process of transformative learning (Fielding 2001). There is a growing body of evidence demonstrating the benefits of student involvement in the development of pedagogical resources (see Bovill et al., 2010). In this case, consulting Aboriginal and non-Aboriginal students in the development of the e-learning environment will ensure that the web-based resources align with the knowledge base for other students.

Before the videos were made publically available online, the presenter reviewed them to verify that the material was handled correctly in the editing. This final cycle of evaluation lead to the collection of further audio material from an interactive face-to-face presentation, which was interleaved into the videos to form the online version of the presentation, now called 'the workshop'.

Stage Two

The second stage dealt specifically with the web based workshop and drew on the expertise of practitioners and specialists within Aboriginal Education and those with expertise in the development of online learning environments.

The first cycle of evaluation involved reflecting on the usability of the web based workshops and the services that will be needed as the project develops. The videos were placed online in an interface developed for the project, which allowed uploading of the material, and clipping and commenting of videos. To allow us to update and refine online material, we provided a facility where people can link to audio, video and text based comments online. There are always new resources being developed online in the area of Aboriginal knowledge and cultural expression, and the online workshop provides an option for linking these into a coherent knowledge system. A reference team of IT specialists and those involved in similar teaching projects evaluated the workshop interface and these changes were incorporated. Aboriginal and Non-Aboriginal students' will do further evaluation as users of the interface in the third stage.

The second cycle of evaluation involved a brainstorming and discussion amongst the extended research team and representatives of an Aboriginal Cultural Reference Team (ACRT) about the learning needs of students viewing the workshop. The ACRT is made up of Aboriginal people who are also long-time educators, who have been invited to be involved in assessing the material and providing feedback on the teaching framework.

This first session with the ACRT also took into account the fact that the physical interaction of the face-to-face workshop would be missing in the online environment and as such we needed to identify and provide more learning tools to compensate for this. For example in moving from a face-to-face interactive workshop to an online environment, it was identified that:

- The workshop would lack the simple role-play exercises that are used by Riley in the face-to-face interactive presentation, which are vital for students to feel cultural connections. Therefore these were developed in flash and inserted in the workshop stream.
- The workshop should be viewed without the distraction of comments in the first run through and then in subsequent reviews the students can see the inserted comments.
- The separate components of the workshop should be accessible to students together in a single screen view to retain the topic order, however this sequence of topics can be stepped through to find points they wish to review.

The presenter and the research team then reviewed the changes to the workshop. Further amendments are being considered, and these will be tested with Aboriginal students and community members when they add their narratives in the next stage.

The final cycle at this stage was the development of a more structured teaching framework as described in the next section. This review was carried out with discussions with community members at public forums and private discussions. This included presenting the project and discussing its aims at the NSW Aboriginal Education Consultative Group Conference. Also the presenter visited her own community and talked with Aboriginal Education workers, who had been involved in previous face-to-face interactive Kinship presentations, about their suggestions to developing the workshop into an interactive online simulation.

To continue this process, we will meet regularly with the ACRT to access their expert knowledge and obtain feedback on the cultural content, ensuring we avoid mis-representation. They will also advise on educational delivery and resource development to support the on-line workshop.

Teaching Framework

In adopting a reflective approach that incorporated stakeholder feedback, the teaching framework was developed from the interactive Kinship presentation and the online interface was edited to include the extra material that had been collected as relevant to each theme of the workshop. The details of this process have been published previously (Kutay, et al, 2012). The next stage was to take the feedback from the stakeholder consultations and develop the teaching goals and strategies to be implemented in the online workshop and simulations.

From engaging with various stakeholders, the first cycle collected information that enabled us to identify the following set of requirements:

1. The project needs to ensure the learning is not too confrontational, and reduce the guilt effect, and focus on enabling understanding of the issues (themes).
2. The simulation should provide a flow from the information provided in the interactive presentation (or its online format) to Aboriginal people's experience of the cultures in conflict. The stories need to be linked to this original information to reinforce the concepts.
3. The simulations need to be immersive, where the environment is encoded with rules and attributes that guide feedback on actions.
4. The online workshop needs to provide tag categories that will automatically generate relations between stories when they are uploaded and can be used to automatically link stories into learning paths in the simulation. The links will help:
   a. modeling stories the user should hear next based on what they have heard before; as well as
   b. select questions to ask after each scenario.
5. Users need to be able to click on an object for more information (these are the interactive presentation comments already collected).
6. The online workshop needs to include different types of scenarios which students may be placed in. These include:
   a. becoming professionals working with Aboriginal communities;
   b. working along-side of members of the Aboriginal community.
7. A series of multiple choice or open-ended questions needed to be added after each scenario.

For the next stage we need to develop the game simulations in line with the teaching framework. The simulations are to be based on generic scenario templates that can be edited by the teacher to suit the professional area of the student; location: such as urban or rural; and immersion: whether in role as Aboriginal or non-Aboriginal. The teacher will also select the stories that are relevant within the scenario, and the tagging of stories will assist in placing them within the scenario's learning path.

To carry out the story collection we treated them as comments on the initial video material, which the contributors load to the website and tag with the related section of the workshop. After the stories are collected and used to design the simulation, they will form the voice (and image, if in video format) of the computer simulated models in the game.

To collect narratives we are running the interactive presentation, and using the online workshop to present the themes and then ask Aboriginal students and community members to comment. The first stage will be conducted via forms of focus groups where Aboriginal people will be asked to discuss the online workshop's content, and then suggest the sort of narratives and stories Aboriginal people may wish to add to this. The focus groups will be designed to ensure that this method is consistent with Aboriginal knowledge sharing practices. We will then arrange a suitable time to collect the narratives in face-to-face interviews and in a manner consistent with Aboriginal protocols. There will also be an option for the contributor to directly record their story and upload it to the site for moderation, so we also will assess the usability of this uploading system.

Conclusion

This paper presents a snapshot of the *Indigenous On-Line Cultural Teaching & Sharing* project. We have shown a new approach to transmitting Aboriginal cultural knowledge from a one-person interactive presentation to an on-line experience, which will provide a sustainable way to continue this teaching program and benefit a greater number of students and teachers. This will additionally provide a portal for an increased number of Aboriginal people to add their narratives and so increase the depth of learning in the areas of historical and imposed structures and their effect on Aboriginal people, retaining this knowledge for future generations. This learning will assist professional practitioners to gain insight and provide improved services in working with Aboriginal people, both as clients and colleagues.

Whilst our project is focused specifically on Aboriginal Kinship, we are also developing online teaching resources, in consultation with Edith Cowan University, who have developed similar material relating to the Nyungar (Aboriginal) experience of Health in Western Australia. We therefore present this work, including the online sharing tools and the process for developing a teaching framework, as having applicability to and across other teaching projects.

In keeping with the reflective and adaptive learning and teaching philosophy underpinning it, this project is developing the simulation games using a modeling approach that provides flexible links to both the particular narratives used in a context, and the questions to be asked that relate to these stories. As the narratives can be continually added to the repository, we ensure that new stories will be available to be selected and used by teachers, and the choice of simulations continually updated.

Web 2.0 as a Catalyst for Rethinking Teaching & Learning in Tertiary Education: A Case Study of KDU University-College (Malaysia)

Alwyn Lau
KDU University College

Web 2.0 signals a move away from the Internet as a passive collection of computers sharing information to the Web as an active network of people who collaboratively shape and create new realities. This paper outlines five trends impacting education as a result of the Web 2.0 phenomenon (connectivism, digital creation, collaboration, divergent assessment and open courseware) then shares the research performed on facultt and students of KDU University-College, the first college in Malaysia to implement an e-forum for the Malaysian Ministry of Higher Education's compulsory subjects.The research asks questions about the benefits and/or challenges which Web 2.0 have brought to teaching and learning, the extent to which the five characteristics have impacted the students, lecturers and management and other issues. It will highlight key findings and recommend broad action-steps forward, both in the national and global context.

Keywords: Web 2.0, e-learning, open learning, assessment, connectivism, education, collaboration.

Web 2.0 (An Introduction)

Web 2.0 is the wave of Internet usage characterized by collaborative sharing, blogging, real-time journaling and other media applications broadly lumped under the heading of 'social networking media'. These applications would include the popular tools and websites like Facebook, MySpace, Linked-In and Bebo, all of which are (understandably fuzzy) expressions of the move towards the creation of online communities and networks which harness the collective intelligence (O'Reilly, 2006).

Web 1.0, being the first 'wave' of Internet familiarity and usage, focused on what individuals can do online qua individuals. These common tasks would include downloading files, creating a (usually static) Web presence in the form of personal websites, viewing and listing information and browsing in general. Web 2.0 signals a move away from the Internet as a mere collection of computers passively sharing information to seeing the Web as an active emergent network of people who are enabled to not only interact more closely but to collaboratively shape and create new realities. From the initial emphasis of consuming what was 'out there', now surfers are acting as 'pro-sumers' who use and share objects and cyber-goods for their own use and satisfaction.

Drumgoole (2006), in true intuitive Web 2.0 fashion, writes in his blog that: "Web 1.0 was about *companies*, Web 2.0 is about *communities*…Web 1.0 was about *wires*, Web 2.0 is about *wireless*…Web 1.0 was about *owning*, Web 2.0 is about *sharing*… Web 1.0 is about web *forms*, Web 2.0 is about web *applications*… Web 1.0 was about *hardware* costs, Web 2.0 is about *bandwidth* costs."

In a word, Web 2.0 is a new *state of mind* (Heuer, 2006) on how to be, behave and engage with the global Web community.

Web 2.0 in education is a sub-component of the more generic term, e-learning, in that the latter involves any and every use of the World Wide Web for educational purposes. Bates (2004) notes that since 1995 when the World Wide Web emerged, online universities have bloomed ranging from public and private partnerships to national and international consortia to the creation of virtual schools.

However, e-learning prior to Web 2.0 involves primarily *supplementing* traditional pedagogical modes with an online component (e.g. clicking on the correct answers, obtaining educational materials online) whereas social networking encourages a more constructivist approach which makes deeper use of reflection and discussion, and in which educational design is reconsidered (e.g. e-forums, collaborative learning, problem-based learning, etc.).

Five Trends in Web 2.0 & Education (A Literature Review)

This essay will first outline five trends impacting education as a result of the Web 2.0 phenomenon. It will argue that Web 2.0 has and will continue to transform e-learning such that educational institutions (and pedagogical thinking) will be unable to ignore the emergence of the below characteristics

Connectivism

This is a theory of learning which acknowledges to the extent to which the learner has connected (digitally) with learners (incl. non-human ones) with divergent views. Developed by George Siemens (2005), connectivism pulls together our understanding of learning with and 'into' the Web, making the former inseparable from a continually productive use of the latter.

Often contrasted with other learning theories like behaviourism, cognitivism and constructivism, connectivism is the latest (re)definition of what learning *is*. This question is undeniably significant in a world where computers and the Internet have become ubiquitous and whole economies rely on them. No longer, argues writers like Siemens, can learning be understood as the mere replication of observable behaviour (i.e. behaviourism), the coding, manipulation and re-presentation of information (i.e. cognitivism) or even the creative design and building of new objects or meaning (i.e. constructivism).

Learning cannot be fully understood apart from the phenomenon of forming connections. Too much complexity has emerged in the world such that *competence* and *mastery* must be seen as a function of being linked to divergent networks, non-human sources and interactive nodes; of being able to 'see' new connections and to distinguish significant from non-significant ones; of making sound decisions about one's learning (as an act of learning itself); even, especially in the context of Web 2.0, of being able to "store one's knowledge in one's friends" i.e. the understanding that one's learning grows together with one's number of contacts/friends (see Stephenson).

The principles of connectivism are summarized (Siemens, 2005) as per below (emphasis added):

- Learning and knowledge rests in *diversity* of opinions and is a process of connecting specialized nodes or information sources; nurturing and maintaining connections is needed to facilitate continual learning; the ability to *see* connections between fields, ideas, and concepts is a core skill.
- Learning may reside in *non-human* appliances and *currency* (accurate, up-to-date knowledge) is the intent of all connectivist learning activities.
- *Capacity to know more* is more critical than what is currently known
- *Decision-making* is itself a learning process. Choosing what to learn and the meaning of incoming information is seen through the lens of a shifting reality. While there is a right answer now, it may be wrong tomorrow due to alterations in the information climate affecting the decision.

It is easy to see how the theory forms and is formed by Web 2.0 trends. More and more students are using the Internet as part of their everyday lives, and more and more of them are less and less satisfied with being passive users. Real-time connection, autonomy, total flexibility, continual creation and instant updating are the norms of Web life. Flew (2004) has noted the ways the Internet has evolved from the 1990s' onwards, one of which is how the Web is much more, "integrated into the everyday activities of individuals, the conduct of organizations, and the pursuit of commercial activity."

If the act of being alive is becoming virtually (pun intended) synonymous with being connected (in more vigorous and creative ways), then the act of learning cannot be grasped as if connections were of low importance. This follows on the idea that the act of *working* can no longer remain the same, having been transformed by what Manuel Castells terms the 'network society' which has begotten a new economy which depends, "on innovation as the source of productivity growth, on computer-networked global financial markets, whose criteria for valuation are influenced by information turbulences, on the networking of production and management, internally and externally, locally and globally, and on labor that is flexible and adaptable in all cases." (Castells, 2004)

If this is right, then problems will abound for educators and educational institutions who have not yet made the shift to a connectivist mind-set; lecturers and colleges still promoting rote-learning or failing to incorporate cyber-oriented concepts as a central feature of their teaching are certain to encounter student problems such as boredom, inattention, non-enthusiasm and difficulties linked to differences in a central understanding of what it means to learn.

Digital Creation, Collaboration & Divergent Assessment

A strong corollary of connectivism is that learning outcomes must include a digital-cyber component i.e. digital literacy in the form of technological constructivism and creation becomes a non-negotiable and students (and, most importantly, lecturers!) must be taught to build digital objects *as part of* their learning.

If we are to avoid the destructive disjuncture between students who navigate informally in Web 2.0 contexts but are required to undergo formal instruction in Web 1.0 environments (Lankshear & Knobel, 2005), schools and colleges must build encourage both students and educators to move *higher up* along Bloom's digital taxonomy (Churches, 2009), itself based on the revision to Bloom's taxonomy (Anderson & Krathwohl, 2001).

Again, this is not about just switching from traditional media to cyber-media; it's about redesigning what learning involves and is all about. Educational syllabi, 'task-sheets', homework and other learning activities – to be consistent with the tenets of connectivism – must be tied in and inseparable from the goal of nurturing Web 2.0 literacy. Digital-literacy skills (e.g. blogging, podcasting, etc.) ought to be considered as important (if not more so) than information-literacy skills (e.g. referencing, citation, etc.), without rejecting the latter.

Bloom's (or Churches') *digital* taxonomy (see Figure 1) also exposes a potentially gaping divide between the higher-order digital skills that the younger generation of students possess and the lower-order ones which the older generation of educators are as yet struggling with(!).

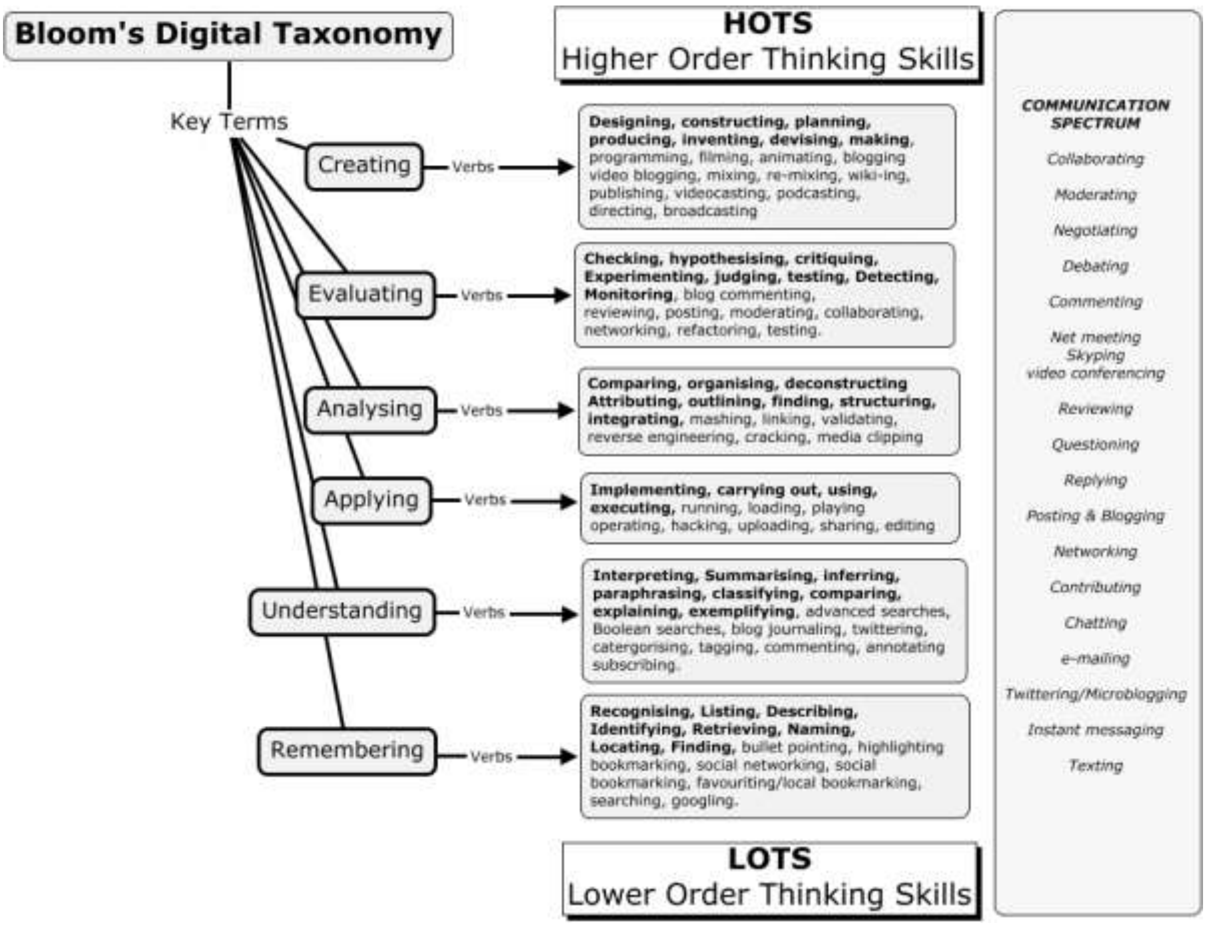

Figure 1: Bloom's Digital Taxonomy (Churches, 2009)

Given this divide, it becomes imperative for educators to ensure that skills like animating, broadcasting, media-clipping and so on are not confined to I.T.- or media-related courses but included even into Business and Social Science courses like Literature, History and Management. Not least also educational institutions would have to begin inserting digital literacy (and even mastery?) as a key criteria for faculty selection, appraisal and promotion.

Lecturer training and induction programs (both in-house and externally sourced) must include the Web 2.0 component. KDU College, in fact, began introducing '21st century learning' as part of its 3-month long faculty induction program and also its delivery of the Cambridge International Diploma for Teachers & Trainers (CIDTT) program; many of the participants of this research are ex-students in these two courses.

Next, if Web 2.0, digital literacy and the new learning network paradigms (Albors, Ramos & Hervas 2008) are to be embedded into education, this would render virtually obsolete the idea of the lone learner. Thus, another effect of Web 2.0 is that learning outcomes must include teamwork and collaborative projects, a not entirely unfamiliar trajectory given the rise of multiple-intelligence paradigms emphasizing inter-personal kinds of smart (Gardner, 1993), studies (e.g. by Ward, 2009) which suggests that students' motivation (at least in the case of classroom writing) may *increase* if they're writing to be reviewed by peers or even external professionals and even calls to prioritize collaboration for the sake of human survival (Goerner, 2007).

Collaboration, simply put, is 'two or more' learners working together on a project, assignment or piece of course material with the objective of producing results they couldn't yield alone. It has reaped profound rewards and opened up previously unimaginable opportunities for businesses and for the redrawing of value-boundaries and knowledge objects (Tapscott & Williams, 2006).

Social networking media then is essentially one huge collaborative phenomenon and – risks of 'bad collaboration' (which is worse than no collaboration) aside (see Hansen, 2009) – if learning is to keep in step with Web-based progress, educators and students alike will have to learn how to connect, work and even 'play' well with others, especially in an age where face-to-face meetings are increasingly rare (despite their benefits, see Young 2008) and team members are ad-hoc, impermanent and relate *only* online. Collaboration as a learning (and assessment) activity promotes the all-too-necessary interpersonal element in personal development and knowledge construction, an often neglected element in academia, as reflected in the continued rejection of Wikipedia as an accepted academic reference despite (or because of) its reflection of 'social knowing' i.e. the idea that knowledge is best shaped through a collaborative conversation and not in an ivory tower (Weinberger, 2007).

It was in the spirit of collaborative learning that KDU College, on the suggestion of this writer, became the first educational institution in Malaysia to launch an e-forum for the Ministry of Higher Education (MOHE)'s compulsory subjects or, in Malay, *Mata Pelajaran Wajib* (MPW). The forum enables students reading Malaysian Studies, Moral Studies and Islamic Studies – the three MPW subjects – to experience 8 weeks (more than half of the 14-weeks allocated per subject) of interactive learning.

Given the changes to learning activities and even the priorities of education, it is only natural to question the means and methods of assessment. Web 2.0 should pave the way for more peer-to-peer assessments, real-world problem-based work and cyber-oriented tests of student performance (not to mention lecturer-appraisals). Furthermore, if learning will take place more and more outside traditional classrooms and will involve establishing rich connections to diverse resources and other people (Lankshear & Knobel, 2006) it is only logical that assessments follow suit.

Open CourseWare

From an institutional perspective, the uploading of free educational material by colleges and universities appears to be imminent and is already made popular by universities like Massachusetts Institute of Technology (M.I.T.) (Thomas, 2007), University of Queensland, etc. In Malaysia, however, open courseware remains a rarity and thus a strong marketing innovation option.

The growing availability of open courseware would, however, be simply a matter of time in a century which has seen shifts in the value of knowledge from its relative *scarcity* to the speed and creativity with which people *share* and *use* knowledge which is free. Nowadays, amateur investigators in almost any field enjoy better facilities for free research and analysis than full-time professionals could buy in previous decades." (Coffee, 2001).

The phenomenon of academic material given free of charge to anyone who can get connected to the Internet is but one more expression of a shift to a culture where value resides in and is created by sharing, networking and collaboration. In this new world, educational institutions who insist of remaining closely protective of and obsessed with ‘intellectual property rights’ (manifested in, say, a great fear that competitors might steal their work) would not be merely missing the point but also missing out on the competitive edge(s) afforded by Web 2.0

Interestingly enough, at the time of writing, no educational institution in Malaysia has carved out a marketing or strategic position via the use of open courseware.

Research on KDU College

Structure, Strategy and Limitations

Qualitative research was performed on selected faculty (incl. management) and students of KDU College (based in Petaling Jaya, Selangor, Malaysia), which has recently had the honour of being the first college in Malaysia to implement an e-forum for the Malaysian Ministry of Higher Education’s (MOHE) *Mata Pelajaran Wajib* (MPW) i.e. mandatory subjects for all pre-university students. The college has also gradually been introduced, via the author’s role in its Teaching & Learning Center, to blogging as a learning and assessment tool, not to mention Web 2.0 as a whole.

Questionnaires were used to compile data in an attempt to answer the following questions related to KDU College:

- What benefits and/or challenges have been encountered as a result of the introduction of Web 2.0 applications into teaching and learning?
- To what extent has the e-forum changed the teaching and learning of the MOHE’s compulsory subjects?
- To what extent has blogging and other Web 2.0 applications transformed the way lecturers facilitate classes and the way students learn?
- To what extent are the (above) five characteristics of Web 2.0 evident in the college and what issues (strategic, executional, etc.) are being faced or anticipated?
- How should the college as an educational institution in Malaysia act with respect to Web 2.0? What are some future steps foreseen?

The sample participants consisted of 30 staff members of KDU College and 23 students. The questions posed were generally simple with at most four distinctions in attitudes. The limited flexibility is necessary to obtain a more definite, if rather broad, categorization of results. I have also designed the questionnaire in such a way as to ‘force’ either a positive or negative response (i.e. all contained an *even* number of alternatives) so as to avoid the fence-sitting I feel is very common among Malaysian respondents.

This research was limited in scope by the following factors:

1. The focus is only on tertiary education
2. The focus is only on one educational institution in Malaysia: KDU College, a private institution offering pre-university diplomas, certificates and external programs with institutions from Australia, United Kingdom, Switzerland, etc.
3. Departments within the college vary in size (e.g. less than half a dozen lecturers for Law but about twenty for Hotel) hence the relevance and applicability of the data could be uneven (both across departments and certainly in any attempt to generalize to the Malaysian industry as a whole).

Highlights of Key Findings

Generally, it is unsurprising that overall students were more familiar with Web 2.0 applications than staff. Among faculty, the Mass Communication and Business departments were clearly the more frequent and familiar uses of Web technology and Bloom’s digital taxonomy (both scored the highest in the first two categories). Remarkably, the Engineering department scored the lowest overall and is clearly the least responsive to Web 2.0 initiatives and potential.

Interestingly enough, one of the items the students ranked highest – fresh applications for learning – is also the item the staff ranked lowest(!). Could this reflect a greater eagerness of the younger generation of learners for novelty in learning and/or a reluctance on the part of academics to change how they teach? Quite strikingly, the staff too did *not* attach overtly huge relevance/importance to the Web as a source of rethinking learning(!).

It could be said that all the departments are positive about the implications of Web for tertiary education. Notable low-scores were the Hotel school regarding the Web *as a source of fresh learning* applications and the Engineering school on the Web *as a tracking/assessment instrument*.

With the Hotel school this may be expected given the very experience-oriented nature of the hotel and tourism industry – as yet there is no such thing as taking a vacation online. As for why Engineering faculty may not be keen on Web-tracking students' work, one explanation could be the nature of the assessments which usually involves working with electronic equipment, machines, their circuitry, etc.

The results of the management mirror tended to mirror those of the Hotel school (and the Staff's response), in that they were relatively unenthusiastic about new online learning applications. This is a rich item to explore as it raises many questions, e.g.:

- Why a low score *here* when the other categories scored relatively high?
- Were the high scores in the other areas due to the subjective, vague and abstract nature of the issues (e.g. 'rethinking learning', 'participatory learning'), whereas online applications have a definite (albeit virtual) element to it i.e. if the program hasn't been seen yet, then it's best not to be welcoming of it?

The staff was most positive about *collaboration* as a key factor in education, suggesting an openness to non-individualistic forms of learning. This resonates well with the above-par interest in rethinking assessments and the use of the Web in encouraging participatory learning. It is disappointing, however, to note that the overall staff response to *blogging* as a means of facilitating learning isn't enthusiastic.

Among the departments, some notable disinterest included the Pre-University department's take on global connectedness as a definition of learning. The Law department also appeared less than fully interested with embedding a cyber-component into the syllabus and providing free materials online.

Analysis & Recommendations

It needs to be stated from the start that, regardless of occasional concerns and lack of interest, overall both students and staff of KDU College have demonstrated a clearly *positive* attitude towards the Web and Web 2.0 as an instrument for the processing and performance of teaching and learning. If the college is at all representative of the Malaysian tertiary education, then the results would indicate much potential in this direction.

The results at least on the surface suggest that those who have a *higher* propensity to view Web 2.0 as an educationally-transforming phenomenon are also:

- those who spend more time online
- those who are more familiar with social media applications
- those with a *lower* academic qualification (in this case, Bachelor's degree and below)
- those who've worked for *fewer* years in education (in this case, less than 10 years)

Without extrapolating too strongly, based on the survey we could make the following recommendations to better nurture Web 2.0 into the spirit and operations of learning institutions in Malaysia:

i) The *Media & Mass Communication* departments should **lead the way in embracing Web 2.0** given the greater openness of the faculty to innovative forms of learning and the constant engagement with new media (which is almost by definition what Web 2.0 is). Given the culturally introspective nature of this area of studies and how difficult it is to draw the line between new media as syllabus, as learning activity and as cultural environment, the departments' students and faculty could be perfectly poised to spear-head projects and events which inform, instruct and infuse Web 2.0 into the consciousness of the organization. At this point, it is important to note that a kind of organizational 'action learning' (Rogers, 2007) may be required before productive implementation of Web 2.0 is witnessed.

ii) The *Pre-University* departments, should educational institutions have one, are also a community well-suited to **support experimentation and development in integrating higher learning with the latest in online social media and technology**. The comparatively less complex and more flexible syllabus may allow greater fluidity in using Web 2.0 applications (although the lesser-trained and generally less exposed students could work against this idea). Nevertheless, the relatively 'shocking' lack of change stimulated by blogging is a key area to address and if nothing else highlights the critical nature of implementation i.e. people may *say* they have a strong interest in something but unless their eventual (and on-going) experience with the item is productive, positive change might be slow in forthcoming.

iii) Disciplines which are skill-based, hands-on and which conventionally are *not* drawn towards emerging media (e.g. *Engineering, Hotel and Languages*) will need **longer preparation cum 'incubation' time before Web 2.0 is fully accepted**; and whilst it'd be certainly unwise to focus Web 2.0-related path-breaking efforts here, it may help to construct ways in which Web 2.0 applications may be embedded as part of the syllabus. This is to say that, given (what could be) a natural disinclination towards Web 2.0, students and faculty may have to experience its full-blown benefits before being willing to take further steps.

iv) From the perspective of specific faculty members, without at all alienating the more senior lecturers and professors, the results imply that revitalizing education with Web 2.0 may be an **endeavour best led by the junior members of staff and/or those with fewer years in education**.

v) From the perspective of the *students*, it may be prudent to **not introduce overly unfamiliar assessment techniques until a later phase.** This is to avoid the anxiety normally associated with passing and excelling in examinations and/or to help ease the transition to new forms of *testing* by first ensuring that students are accustomed to new forms of *learning*.

It must be duly noted that should an educational institution seriously embark on a Web 2.0 mega-project, there will be a need to manage the potential political backlash resulting from various departments and even 'classes' of faculty taking the front-seat. Nobody ever said change was easy.

*

Bill Gates, founder of Microsoft, once said that the Internet is the town square of the global village that is our world of tomorrow. If education is to play a key role in shaping the thinking and direction of this global village, this entails that schools and colleges have to do serious business with the Web and all that it offers and represents.

The phenomenon of Web 2.0 is an advent promising transformation for educational institutions willing and able to take bold steps to devise empowering faculty- and student- combinations of experience and experimentation to take their repertoire, *modus operandi* and service-offerings forward in to the future - both real and virtual.

Title: Computer-mediated collaborative learning in large first-year STEM classes facilitating interdisciplinary scenario-inquiry tasks

Gwendolyn Lawrie
School of Chemistry & Molecular Biosciences
University of Queensland

Gwen Lawrie (PhD, BSc App Chem, GDip Ed) is a Senior Lecturer in the School of Chemistry and Molecular Biosciences at the University of Queensland. She transferred to a teaching-focused appointment in 2008 from a bench chemistry research background and is currently a 2012 UQ Teaching Fellow. Gwen was a 2010 CASTL (Carnegie Academy of the Scholarship of Teaching & Learning) Institute Scholar and leader of two ALTC T&L projects. Her teaching and learning projects to date have addressed the diversity and engagement of students through collaborative inquiry tasks and technology enhanced active learning environments.

Kelly Matthews
Teaching and Educational Development Institute
University of Queensland

Kelly Matthews is currently a Lecturer in Higher Education in the Teaching and Educational Development Institute, and is completing her PhD. Her research involves practical applications into contemporary higher education issues including undergraduate curriculum reform, and evaluation of teaching and learning initiatives. Her interest in undergraduate science students' quantitative skills involves research into the interdisciplinary nature of science and mathematics including interdisciplinary curriculum development and subsequent student learning outcomes. Kelly is involved in a range of teaching and learning projects through a network of local, national and international collaborations, and she publishes in the area of Science and Mathematics Higher Education.

Intended audience and degree of expertise/past experience required

Lecturers, course coordinators and secondary teachers who have an interest in assessment of collaborative learning environments, particularly in large classes/sections, will find this session of great interest. Strategies for managing collaborative groupwork while evidencing individual contribution are shared including effective peer assessment. Participants who are interested in promoting interdisciplinary thinking in their STEM classes are also encouraged to attend. No past experience is necessary to engage in this workshop.

Statement of objectives for the workshop

Interdisciplinary scenario-inquiry tasks (IS-ITs) have been developed to both enhance engagement and address the diversity of abilities and interests common to large, undergraduate first year chemistry cohorts at UQ. Facilitation and assessment of these slef-directed tasks in large-enrolment courses is too complex and time-consuming for a single academic course coordinator to manage manually; hence, **i**nteractive **C**ollaborative **A**ssessment **S**ystem (iCAS – a computer-mediated task-management and assessment system) has been developed to achieve these processes. iCAS facilitates flexible group formation enabling promotion of student investment in both the process and outcomes of the task. Interdependency within groups has been generated by combining an individual research quest, which requires students to generate information files, with a collaborative challenge which relies on integration of all the individual sets of information to generate a collective product. The objectives of the workshop are to:

- engage participants in the pedagogical challenges of implementing tasks of this nature to maximize and measure learning outcomes.
- share strategies for group formation and interdependence.
- consider assessment of collective written products for evidence of interdisciplinary thinking and higher level learning outcomes.
- manage effective peer assessment and feedback through a task management technology.

Facilitators will lead collaborative activities and discussions to demonstrate the multiple factors that integrate to make these tasks viable including. Outcomes of this workshop will be provision of a model and resources that can be translated to other STEM disciplines and any class size

Detailed description

Implementation of group work in large classes (>500) presents challenges around task design, implementation, management and assessment. Computer-mediation enables group formation and function: student investment in both the process and outcomes of the task is promoted by allowing them to choose their preferred scenario topic and by providing the option for them to self-select into/or from their preferred groups. Interdependency within groups of four is generated by requiring each student to complete separate individual research quests to generate information files required by the whole group for the collective product. Individual quests have been constructed so that the collective outcome would be of lower quality if one of the four sets of information was missing. Once the collective product is submitted, the iCAS task management and assessment system directs students through two separate peer assessment domains: evaluation of the contributions of their own team members; and individual assessment of other group's products within the same scenario promoting reflective processes.
This workshop is structured to enable participants to explore and assemble the components of the task and gain insights into the factors that influence the learning processes and products. The sequence of workshop is proposed to be:

Introduction: engagement and orientation into workshop

Activity 1: Interdependency & Communication

- Participants will be engaged in an activity that generates evidence and demonstrates the role of interdependency in collaborative tasks.
- Facilitators will share common misconceptions of how students work collaboratively outside the classroom. Strategies for promoting interdependency in activities that progress outside the classroom will be presented.
- Discussion question: What are the inherent challenges in engaging students in formative assessment?

Activity 2: Interdisciplinary Thinking & Creativity

- This activity helps participants explore how individuals bring prior experiences and perspectives that combine to generate shared understanding and an interdisciplinary product. This activity is set in the context of 'Infinity'.
- Facilitators will introduce participants to assessment of the collective products of group tasks in terms of integrated ideas and higher order thinking (including exemplars of a range of student products).
- Discussion question: What options are available for assessing collective products of inquiry-based group work?

Activity 3: Web-Based Management of Collaborative Group Work

- Participants will be introduced to the characteristics of a successful collaborative student group through case studies and how to use related indicators to monitor group function.
- This brief activity includes a hands-on practical challenge that will engage participants in teamwork themselves.
- Participants will be introduced to the online peer assessment management tool that promote students' reflections on their own participation and develop their skills in professionally reviewing peer products.
- Discussion question: How can collaborative group work be sustained and evidence of individual outcomes within a group logged?

Conclusion

Brief reflection on the session, feedback and evaluation. Distribution of resources to participants including Interdisciplinary Scenario Inquiry Task Resource Handbook developed as part of the 2009 ALTC project 'IS-IT learning? Online interdisciplinary scenario-inquiry tasks for active learning in large, first year STEM courses' (CG9-1112).

An e-portfolio theoretical approach for Provisionally Registered Teachers

Maryann Lee
Centre of Educational Design and Development
Faculty of Education
University of Auckland

Lesley Pohio
School of Curriculum and Pedagogy
Te Kura o Te Marautanga me te Ako
Faculty of Education
University of Auckland

Electronic portfolios offer an option for early childhood provisionally registered teachers (PRTs) to attest to the Registered Teacher Criteria (New Zealand Teachers Council, 2010) through the purposeful selection and reflection of significant artifacts about their practice. Central to the use of e-portfolios is the theoretical framework developed to support the learning process for the PRTs. This paper outlines an e-portfolio project for a group of early childhood PRTs and their mentors, from a cohort of five Early Childhood Centres in the Auckland region. The project drew upon key principles from the early childhood curriculum Te Whāriki (Ministry of Education, 1996), pedagogical documentation, and e-portfolio best practice. The project's intention was to create a more effective approach for teachers to engage in the provisionally registered teachers programme, enabling a rich narrative of the teacher's pedagogical research to be profiled rather than being a repository of evidence.

Keywords: e-portfolios, provisionally registered teachers, early childhood education**,** pedagogical documentation

Background

While e-portfolios existed as early as the 1990's, only in the last decade have they have become significantly widespread within educational settings, both in New Zealand and internationally (Fox, Britain & Hall 2009; JISC 2008). This recent and rapid evolution of e-portfolios has enabled educational institutions to adopt the technology for a range of purposes. E-portfolios are often positioned as either a *product* whereby focus is placed on the final presentation or completion of the e-portfolio, or as a *process,* which shifts the focus to the designing and building of an e-portfolio (Barrett, 2011). Tensions exist between the two approaches: the first often seen as an institutional tool for accountability purposes, and the tracking of student's progress; and the latter drawing attention to the learning journey, that supports a more learner centered approach of learner autonomy and reflection.

The challenge for many educational institutions is balancing external motivators, such as grades and required learning standards with the more pedagogically focused framework that promotes greater learner ownership and autonomy (Stefani, Mason & Pegler, 2007). Learners need clear guidance around the learning intentions and assessment expectations, and at the same time be given agency of their e-portfolios. Rather than a *tick box* compliance model, e-portfolios must support a holistic approach that is meaningful and authentic. This is essential in enabling learners to engage in life long learning, and to continue to incorporate their e-portfolios in future learning opportunities that are embedded and integrated in their professional practice.

For many educators, authentic learning takes place for students when greater emphasis is on the "rich and complex processes of planning, synthesizing, sharing, discussing, reflecting, giving, receiving and responding to feedback" (JISC, 2008, p. 6). On this premise many Teacher Education programmes have adopted the use of e-portfolios as a learning approach to promote students' inquiry and reflection (Shepherd & Skrabut, 2011). For example, in recent years at the Faculty of Education, The University of Auckland, e-portfolios have been used as both a place for students to engage in critical reflection in their course work and practicum placements, and as a receptacle of evidence that they attest to the *Graduating Teacher Standards*. Through the use of e-portfolios graduating students have the ability to demonstrate their learning by drawing on a range of significant artifacts that they can continue to use and reflect upon as practicing teachers.

E-portfolios are also becoming more widely explored as a learning tool for New Zealand registering teachers to meet their registration criteria. This paper describes an e-portfolio project that brought together a cohort of centres to implement the use of e-portfolio to 20 PRTs, who were all at varying stages of the registration process. The intention was to create an integrated e-portfolio approach that enabled teachers to authentically investigate their areas of learning, as well as attest to the *Registered Teachers Criteria* laid out by the Teachers Council (NZTC, 2010). An e-portfolio theoretical framework and approach was developed that aligned e-portfolio best practice and drew from the underpinning principles of *Te Whāriki* (MoE, 1996). It also included the notion of pedagogical documentation that provokes teachers to reflect on their practice through the documentation of children's learning experiences in relation to the *Registered Teacher Criteria* (NZTC, 2010).

The e-portfolio platform chosen for this project was MyPortfolio, which was established by the Mahara project as a collaborative venture funded by New Zealand's Tertiary Education Commission's e-learning Collaborative Development Fund in 2006 (Mahara, 2012). MyPortfolio provides a learner centred environment that is both flexible and easy to navigate, and promotes the integration of digital media and online learning tools. The collaborative features within MyPortfolio supports strong engagement for an online community of learners. A critical component of the software is the ability to easily share e-portfolio pages to selected audiences and to receive feedback within a variety of forums. The MyPortfolio technology enabled the PRTs to develop autonomy and agency of their e-portfolios and aligned closely with the aims of the project.

Literature Review

Pedagogical Documentation

Pedagogical documentation and assessment of children's learning is a core component of teaching and learning in early childhood education (Felstiner, Kocher & Pelo, 2006; MoE, 1996). Pedagogical documentation is considered as a way of making learning (and teaching) processes visible to children, their families, teachers, and the broader teaching and learning community. This documentation of children's learning includes artifacts such as photographs and narratives that illustrate a particular experience, exemplars of children's work, video clips or transcripts of engagement. The inclusion of the teachers' reflective commentary and voice moves the documentation into a more purposeful and meaningful process. Rinaldi (1998) proposes that "[pedagogical] documentation makes it possible for teachers to sustain children's learning while they also learn (to teach) from the children's own learning" (p.120).

The focus on pedagogical documentation in early childhood education in New Zealand, has in part, been influenced by the pedagogy of the Reggio Emilia early childhood centres in Italy (Carr & Lee, 2012), alongside the early childhood assessment for learning exemplars *Kei Tua o te Pae* (MoE, 2004). Rinaldi (2006) emphasises the value of pedagogical documentation "as a tool for recalling; that is, as a possibility for reflection" (p.63). Millikan (2003) also claims that pedagogical documentation provides for many inherent possibilities such as "leading an inquiry forward, being a tool for children's own reflections, enabling parents to view and contribute to the process of children's learning, for teachers' professional development, and as an advocacy for children" (p. 102). The multifaceted nature of pedagogical documentation helps teachers to understand how young children learn and how they can respond in an intellectually engaged way. As part of this process teachers must ask themselves what image of the child is being portrayed through the documentation and what theories of teaching and learning the documentation may be implicitly reflecting. When pedagogical documentation is viewed in this way, it can cause teachers to more critically review their practice and the opportunities for enriching children's learning (and teachers' teaching).

A significant component of pedagogical documentation is the teacher's own reflective text or commentary. Gandini and Goldhaber (2001) believe the process of documentation can be catalyst for change causing early childhood teachers to see themselves differently thus, "expanding their identity from nurturer and caregiver to include theoretician and researcher" (p. 143-4). That said, without the addition of the teacher's "reflective commentary" the artifacts on their own, only tell some of the story (Felstiner, Kocher & Pelo, 2006, p.57). The documentation therefore serves the purpose of not only highlighting children's learning experiences but the underlying work of teachers. Rinaldi (2006), sums up, “When you take a picture, or you make a document, in reality you don’t document the child but *your* knowledge, *your* concept, *your* idea (p.196).

E-portfolios

Throughout the literature there are numerous definitions and descriptions of an educational e-portfolio. Themes about learner autonomy, reflection, and online collaboration are among the key benefits identified in the use of e-portfolios (Fox et al 2009). According to Banks (2004), e-portfolios are a place for students to reflect on their learning as well as a place to record and celebrate their achievements and goals. He advocates the potential for e-portfolios to re-purpose information so that it can be presented and shared to different audiences and transferred across different systems. Barrett (2011) promotes e-portfolios as a space to authentically voice stories, enabling learners to reflect on their personal learning journey, and to share their insights with chosen learning communities. JISC (2008) also describe the e-portfolio as learner driven in a space where students’ learning and achievements are demonstrated by a collection of artifacts. JISC (2008) acknowledge the learning journey that accompanies the creation of the product and highlight the importance of engagement and reflection as integral to the learning process.

An e-portfolio process enables learners to reflect at each stage of their learning. In particular learners must reflect carefully about their selection of individual artifacts, as well as on their e-portfolio learning journey (Barrett, 2011). A key component throughout the e-portfolio process is the sharing and engagement with others, whereby formative feedback from peers and mentors can take place within online communities of learners. DiBiase (2002) outlines an e-portfolio process that can be described in five key stages. Each stage is intertwined with the other and provides a framework for learners to progress through their e-portfolio journey. The stages include;

- Collection: teachers and students save artifacts that represent achievements in their learning and practice (i.e. reflections and assignments).
- Selection: teachers and students review and evaluate materials that are significant to their learning goal.
- Reflection: teachers and students provide reflective commentary on their selection of artifacts.
- Projection (or Direction): teachers and students review their current achievements or learning outcomes with key criteria.
- Presentation: teachers and students share their portfolios with teachers and peers to celebrate their learning.

The scope of e-portfolios in tertiary institutions has been more recently extended by the development of Web 2.0 technologies (Roder & Brown 2009). Tools such as blogs, discussions, wikis and RSS feeds have fuelled a significant increase in online social networking over the last five years. Strong collaboration and engagement amongst social networks spaces enable users to engage in creative and collective authorship (Shepherd & Skrabut 2011). Barrett (2011) explores the boundaries between e-portfolio development and social networking and acknowledges the large impact it is having both on our social and political world. She advocates the use of social networking with e-portfolios to increase students’ intrinsic motivation. Social networking tools are similar to e-portfolios in that they promote interactivity and collaboration through “connecting or “friending”, listening or reading posts, responding or commenting and sharing through linking or tagging” (p. 7).

E-portfolio Project

This section provides a descriptive overview of the theoretical framework and e-portfolio approach that was developed for a cohort of early childhood provisionally registered teachers (PRTs). The approach and processes described have been drawn directly from the documentation provided for the implementation of the PRTs e-portfolio project. A research study will follow to capture the teacher’s experiences and depth of e-portfolio engagement throughout the registration process.

Theoretical Framework

The development of a theoretical framework prior to the implementation of the e-portfolio was an essential component to the e-portfolio approach. In the absence of a clear understanding of this framework by teachers, the e-portfolio risked becoming a repository of information, rather than a rich narrative of the teacher’s pedagogical research. Orland-Barak’s (2005), e-portfolio research, cautions against the popular view that, “the mere construction of a portfolio automatically yields critical levels of reflection on action" (p.41). Therefore, a strong framework was needed to equip teachers to investigate their learning with a greater sense of purpose and value in the e-portfolio reflective process.

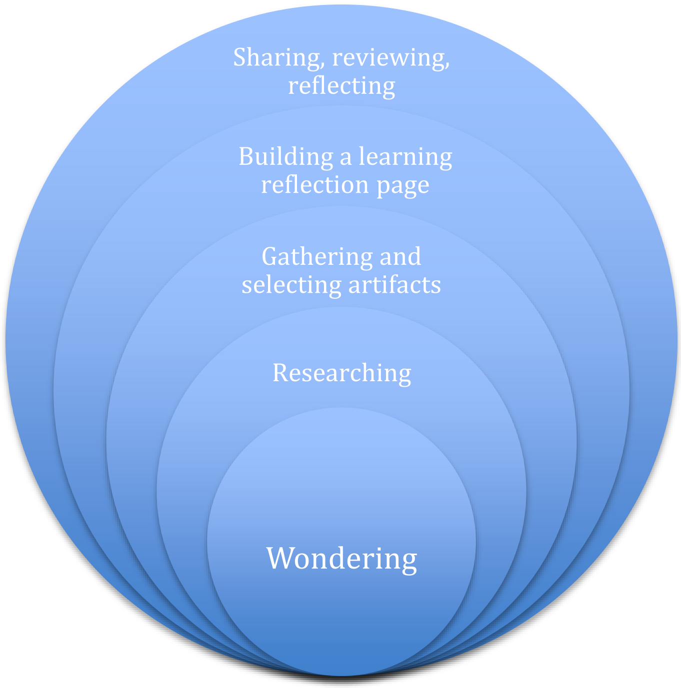
Underpinning the framework is the early childhood curriculum *Te Whāriki* (MoE, 1996). There are four foundation principles within *Te Whāriki* (MoE, 1996) that provide valuable reference points for teachers when engaging in the e-portfolio process. The interwoven nature of these principles is likened as a whāriki, or mat, whereby each early childhood context weaves their own distinct patterns of curriculum creating a unique and contextualised interpretation. *Empowerment-Whakamana* advocates for early childhood education services that enable young children to develop a sense of self-worth and identity. *Holistic Development-Kotahitanga* provides a model of learning that brings together all aspects of the child and their experiences. *Family and Community -Whanāu Tangata* emphasises the importance of the integral role that family and community play in early childhood education and in young children's learning. *Relationships-Ngā Hononga* promotes learning environments where responsive and reciprocal relationships with people, places, and things are established (MoE, 1996).

A critical goal of the *Registered Teacher Criteria* (NZTC, 2010) for all teachers regardless of the sector, is to provide an "aspirational framework of continued professional learning and development that will impact on the learning outcomes of children" (p. 2). The criteria outlines, four overarching statements that guide and inform the criteria themselves and underpin the professional dimensions and indicators. This document is designed as a description of the criteria and to provoke professional dialogue between teachers and mentors.

Central to the theoretical framework was the notion of pedagogical documentation that enabled teachers to reflect on their own practice through the documentation of children's learning experiences (Rinaldi, 2006). Although the primary purpose of the documentation is the child's learning, inextricably intertwined within this process is the ability of the same documentation to reflect the quality and nature of the teaching and learning relationship. Rinaldi (1998) proposes that "[Pedagogical] Documentation makes it possible for teachers to sustain children's learning while they also learn (to teach) from the children's own learning" (p.120). Teachers may ask themselves questions such as; what image of the child is being portrayed through their e-portfolio? What do the artifacts selected say about their values and beliefs about teaching and learning? How might their e-portfolios inform them to more critically review their practice? Through this process of developing and reflecting on the their e-portfolio the teacher's documentation can be a catalyst for change causing early childhood teachers to see themselves differently thus, "expanding their identity from nurturer and caregiver to include theoretician and researcher" (Gandini and Goldhaber, 2001, p. 143-4).

A Cyclical Approach

A cyclical approach was required to ensure an active and dynamic, reciprocal process that was responsive and reflective, provoking further opportunities (and wonderings) for teaching and learning. Positioning teachers as researchers was a critical component to the cyclical approach. Teachers were encouraged to employ principles of action research that supported a collaborative approach to learning, through actively enquiring, reflecting and co-constructing new knowledge in a cyclical nature (Milton-Brkich, Shumbera & Beran, 2010). This process allows teachers to research in an iterative way, engendering a spiral approach of new learning and new action generation. Punch (2005) considers that "the spiral of cycles of self-reflection, involving planning, acting and observing, reflecting, re-planning and so on, has become a dominant feature of action research as an approach" (p 162). The processes outlined below support teachers to define and refine their evolving understandings rather than as a linear formular to follow.



Cyclical Approach

Figure 1: Processes to developing an e-portfolio through a cyclical approach

Wondering
Developing a wondering is the first critical stage in articulating an interest for further action research (Dana and Yendol-Hoppey, 2009). The concept of a wondering aligns with the early childhood education assessment for learning process of "noticing, recognising and responding", whereby teachers search, in collaboration with children for possible directions and opportunities for teaching and learning, in response to children's interests (Ministry of Education, 2004, p. 6). In this initial stage, teachers are encouraged to notice, recognise and respond to a teaching and learning moment(s) that has captured or provoked their thinking. The wondering provides a guide for the PRTs to focus their research on a particular area of intrinsic interest. It is carried out in collaboration with a mentor and in the context of their early childhood centre. An exemplar of a wondering description called Making Learning Visible through Visual Art was provided to PRTs as outlined below.

> My wondering began when my conversations with a child were significantly enriched through her visual artwork. I began to realise that through visual arts children could articulate their own stories and working theories more deeply - making their learning visible. I wondered how often as teachers we in avertedly privilege the verbal and pay lip service to other forms of communication, missing or not hearing the many languages children use to communicate with. In this learning reflection page I am seeking ways to understand how in my practice I can incorporate visual arts more effectively as a means for children to tell their stories and express and represent their own understandings of their worlds, enabling me to listen more closely through these different visual mediums.

Researching
A key component for teachers researching their area of interest is the analysis of documentation of children's learning experiences in order to capture their own pedagogical understandings in their research. The creation and examination of documents allows teachers to investigate in greater depth, promoting meaningful reflection and evaluation of authentic learning experiences. Through the lens of their wondering, teachers undertake critical conversations with their peers and mentors, seek professional learning opportunities and source literature to inform their research. The documentation from their research becomes artifacts that can be selected for the teachers'

learning reflection page. Examples of artifacts may include;

- Critique of significant literature
- Learning stories (individual or group)
- Reflection or journal entry (i.e. a parent or whanau meeting, professional learning events, mentor meeting)
- Sequence of photos showing children's learning experiences
- Links to relevant websites and resources
- Photos of a resource identified at another centre
- An audio recording of a dialogue between children / teachers
- A video of children's engagement with the environment (i.e. a nature walk)
- Parents feedback on their child's portfolio

Gathering and selecting artifacts
When early childhood teachers make decisions about what to include or highlight in a learning story, they use their own pedagogical understandings to inform their selections. The same premise applies for teachers selecting artifacts for their e-portfolios - deliberate decisions about selection are based on teaching understandings and reflection on individual learning journeys. Teachers must carefully reflect on their chosen artifacts to critically review their practice, and enrich the opportunities for children's learning (and teachers' teaching). Throughout the process of selection, teachers may ask themselves the following questions;

- What concept or idea does this artifact reflect?
- What is the purpose or significance of this artifact for my (and children's) teaching and learning?
- How does this artifact reflect a competent and confident image of children?
- Does this artifact reflect a critically reflective teacher?
- In what way does this artifact develop my understandings in relation to my wondering?

Building a learning reflection page
An e-portfolio is made up of a number of learning reflection pages that are developed throughout the registration period. Each learning reflection page is built over time and involves drawing upon significant learning experiences to illustrate a deeper and more developed pedagogical understanding. The building process enables teachers to continually critique and refine the content and understand the overarching sense and meaning the page may reflect. It also engenders opportunities for the teachers to revisit their professional practice and engage in deeper meaning making of these significant experiences.

The building stage is both a creative and reflective conceptual process that requires the learner to draw their individual artifacts and reflective commentaries together as a cohesive entity through the lens of their wondering. While teachers continue to make careful decisions around their selection and placement of their artifacts, a pivotal component of their page, are the *reflective commentaries* that are written to accompany their artifacts. These personal reflections provide a further layer for teachers to make their learning (and teaching) processes visible and through their own *voice* demonstrate both the complexities and depth of their learning, in relation to the *Registered Teacher Criteria* (NZTC, 2010). Without the addition of the teacher's reflective commentary, the significance and purpose of the artifacts are often lost. The following example of a reflective commentary was provided to the PRTs.

> I selected these artifacts [teachers observation, sequence of photos, parents voice], as they show my deepening understanding of what it means to 'listen' more closely to children. Previously I thought I was listening to children but was I really 'hearing' what children were saying? Did my own underlying or hidden agenda channel the children's ideas and perspectives into directions I valued and preferred, rather than being open to the different views and ways of being and seeing, children present? Listening involves hearing and responding to the "hundred languages" children use to communicate and express themselves as they engage with people, places and things (Rinaldi, 2006, p.60). I have a professional responsibility to understand the complex social and cultural influences that impact on teaching and learning thereby being able to interpret the unique ways children make their thinking visible (NZTC, 2010). This is an ongoing area of practice that I need to continue to strengthen and explore as I continue my professional journey.

Figure 2*: Example of a Learning Reflection Page showing a variety of artifacts and reflective commentaries*

Sharing, Reviewing and Reflecting

Peer formative feedback occurs throughout the e-portfolio process and is a critical component in promoting greater collaboration, reflection and co-construction amongst a community of learners. Collectively through their inquiry process and engaging with each other, teachers become "active participants in making meaning, and to see learning as initiated by understanding" (Aulls & Shore, 2008, p. 93). New perspectives offer renewed knowledge and can help teachers see what is sometimes familiar and obvious, from a different slant (Filippini, 1998).

A final presentation before a chosen audience is encouraged as a way to celebrate the teachers learning journey and accomplishments within their wondering. Teachers draw upon their e-portfolios to demonstrate their learning by providing authentic learning examples that have developed from their professional practice. Barrett (2011) describes the importance of the presentation as a public commitment, not only to receive meaningful feedback from colleagues, but also to provide motivation for learners to carry out their portfolios.

Mentors also work alongside the PRTs to provide support and guidance throughout the process. At the completion of each learning reflection page the mentor reviews the selected artifacts and reflective commentaries with the teacher. Teachers must be able to articulate and demonstrate, through selected artifacts, the links between their learning and the *Registered Teacher Criteria.* Critical conversations are required to ensure that the registering teacher receives formal and documented feedback on their professional practice, which also enables valuable feed forward for planning the next learning reflection page and further directions for practice.

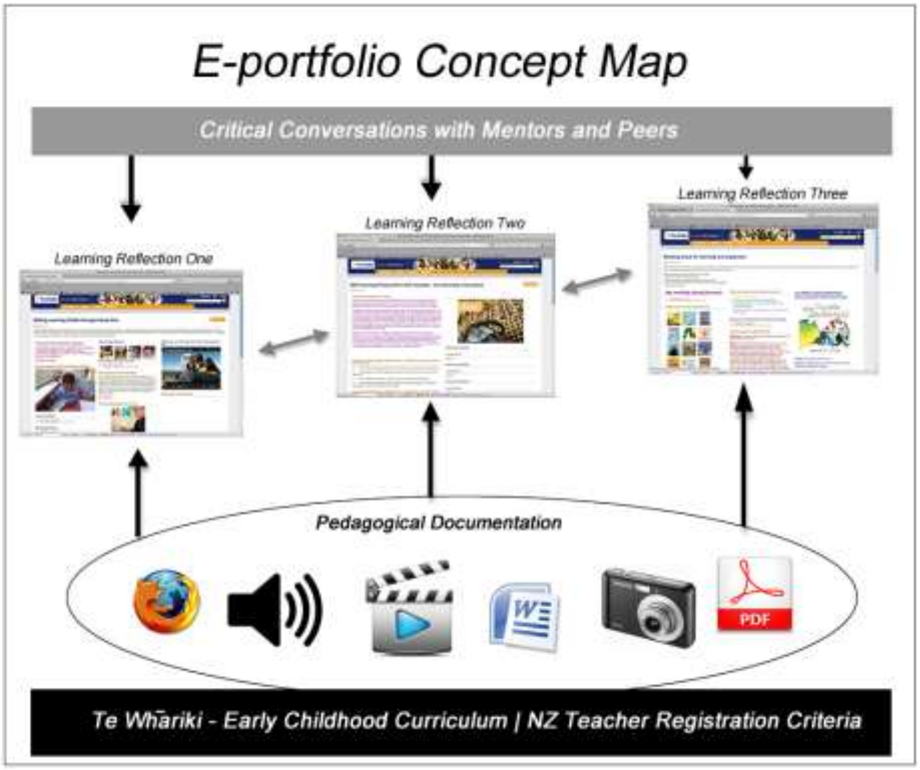


Figure 3: A concept map illustrating the components in developing an e-portfolio

Conclusion

The use of e-portfolios is an effective tool to enhance teachers' professional learning and to attest to the requirements of the NZ *Registered Teacher Criteria*. This project drew upon key principles from the early childhood curriculum *Te Whāriki* (Ministry of Education, 1996), pedagogical documentation, and e-portfolio best practice. It sought to foreground an e-portfolio theoretical framework and approach created for a group of early childhood PRTs. The approach was developed to promote the use of e-portfolios in a more sustained and meaningful way, enabling teachers to continue its use for their future professional practice beyond the registration process. This was critical in supporting teachers to reflect and critique on their professional practice, and to develop greater learning connections and pedagogical understandings over time.

The e-portfolio approach outlined in this paper has placed greater emphasis on the *process* of creating an e-portfolio rather than the final *product.* However, it is the learning process that enables teachers to demonstrate a deeper level of thinking and learning in their product. Through the careful selection of significant artifacts, the reflective commentaries and critical conversations, links to the *Registered Teacher Criteria* (NZTC, 2010) become inherent in the e-portfolio product. Teachers engage in a journey to further their professional growth and gain new understandings about teaching and learning, rather than centering on a compliance model to meet specific standards.

To conclude, e-portfolios offer teachers the opportunity to take their learning into the future. When teachers engage in experiences that have meaning, and provoke further inquiry, they are more likely to sustain that engagement long term. The ultimate aim for teachers, when engaging in the e-portfolio process, is to improve professional practice and the educational experiences and outcomes for children. The creation of thoughtfully constructed e-portfolios provide PRTs a unique opportunity to "listen again, to see again, and therefore to re-visit the experiences of children" (Filippini, 1998, p.132).

Pigeon pecks and mouse clicks: Putting the learning back into learning analytics

Jason Lodge
Griffith University

Melinda Lewis
The University of Sydney

Learning in higher education can be described as a series of complex tasks and stages of development requiring a range of multifaceted behaviours and ways-of-being. Understanding what contributes to teaching for quality learning and achieving quality learning outcomes in higher education has been the topic of much debate over many decades. The current paper intends to situate and contextualise learning analytics (LA) within a broader debate on quality and student experience, outlining the affordances and constraints of this data-driven approach to quality. Firstly, we acknowledge the current use of LA within higher education and early research outcomes reported within the literature. Secondly, drawing on our combined disciplinary knowledge within experimental psychology, health informatics and health science education, as well as our current roles within quality and student experience at our respective universities, we pose some directions for enhancing and building on current approaches to understanding and using LA in the higher education context.

Keywords: learning analytics, quality, student experience

Introduction

What is the purpose of higher education? Is it to train the next generation of professionals to be job-ready? Is it to contribute to public debate? Is it to contribute to the private good of graduates by increasing their earning potential or is it to produce morally and intellectually capable citizens with a capacity for critical thinking and solving the problems facing humanity in the 21st century? We argue that it is a mixture of all of these aims. What then are we to make of the current approaches to ensuring that, as institutions, we continue to achieve or at least aspire to these ends? In this paper, we intend to situate new approaches to understanding and tracking student development within these wider aims. Our intention in doing so is not to heap empty criticism onto learning analytics but to present for consideration a way forward in realizing the potential of analytics in the context of developing students as human beings.

Devlin, Brockett and Nichols (2009) suggest that the best way to ensure that universities are meeting their aims is to examine the quality of the learning experiences of students as they engage with their studies. Despite substantial advances in technology and methods for understanding learning in the higher education setting, there remains conjecture as to how quality learning occurs and how best to measure it (Krause, 2012). From a cognitive science and educational psychology perspective, classroom learning is an illusive and difficult to accurately operationalise phenomenon (Richardson, 1987). The approach to understanding learning in this context usually adopted by educational research, on the other hand, has been criticised for being less than rigorous (Slavin, 2008). Although there is substantial distance between the approaches and epistemology underlying these disciplines, there is general agreement that reductionist approaches to assessing quality learning are limited in their potential for explaining the value-add of higher education (e.g. Hussey & Smith, 2010). When viewed holistically therefore current evidence-based approaches to learning and teaching are lacking with neither laboratory research or classroom studies able to explain the process of learning from curriculum to neuron. Projected from the individual to the institutional level, understanding whether universities are indeed providing quality learning experiences across the gamut of disciplines becomes increasingly problematic.

The complexity associated with attempting to understand quality learning is thus problematic enough without the added complication of increased use of technology in this context. While technology introduces clear benefits and risks, the potential for tracking online engagement, integrating previously separate datasets containing information about students, is a trend that appears to be growing unabated (Seimens, 2012). The use of these approaches raises some concerns within the broader range of factors that serve as indicators of quality learning. The reductionist approach to what is a complex phenomenon is akin to behaviourist approaches used to understand learning in the 20th Century. Are we at risk of treating learning in a higher education context as being analogous to a rat pressing a lever? Yes as we can 'measure' it, or no, as it does not make meaning out of complex notions such as learning in adulthood, learning for professional preparation, learning as research training, learning as development and growth, learning as being-in-the-world? What we are suggesting here is that current data-driven models under evidence-based approaches offer decontextualised data from a range of sources, primarily tracking data from online platforms and systems. What may this add to our understanding of the student learning journey as well as predicting student learning outcomes? Where is the personification and profiling of the individual within aggregated clumps of digitally derived data? We must take the complexity of student learning into account just as the reductionist approach to learning encapsulated in behaviourism was brought to account. The real power and potential of learning analytics is not just to save 'at risk' students but also to lead to tangible improvements in the quality of the student learning experience.

Learning analytics: tracking for quality or quantity?

While the use of learning analytics to track and predict student success in higher education is rapidly becoming mainstream practice in higher education institutions, it is predominantly being used to predict and prevent student attrition. For example, Macfadyen and Dawson (2010) report on an 'early warning system' that utilises a tool for tracking interaction with a learning management system (LMS) to determine which students are not engaging with online material and with each other within the virtual learning space (VLS). Macfadyen and Dawson present a study conducted at the University of British Columbia (UBC) where student interactions within the BlackBoard Vista LMS were tracked and modelled. Student interaction is tracked on a number of dimensions including time online, number of mail messages sent and received, files viewed and visits to the gradebook etc. Within the context of LA, although this kind of tracking is not new, the authors argue that using this data to model/analyse online relationships is new and allows for a more complete picture of student engagement. Macfadyen and Dawson further claim that the resulting model is a powerful predictive tool able to explain 30% of variance in overall grade and can identify with 81% accuracy students who will fail (2011, p 588).

Although there is some face validity to the claims being made by Macfadyen and Dawson (2010) and the model proposed in their paper looks to be useful in assisting students through early intervention, there are a number of issues with the approach. The tools themselves have evolved from analytics used in management and marketing (Baepler & Murdoch, 2010). Common uses of analytics in the commercial world are to predict consumer behaviour and decision-making in order to virtually influence purchasing behaviour, a behaviour less complex than those associated with student learning and attrition from university (e.g. Yorke & Longden, 2004). In rationalising the use of marketing tools in education, Macfadyen and Dawson concede the argument made by Goldstein (2005) that the usefulness of LA in learning and teaching practice has received little attention but there is no suggestion as to why. They argue instead that the increasingly diverse mix of students and underutilisation of these tools justify the presented research. However, a critique of their justification alludes to reasons why LA has not been more broadly embraced. This justification is supposedly based on social constructivism as the theoretical foundation for the research. They suggest that their approach can accurately gauge the engagement of students in a 'learning community' and that this places the framework within the social constructivist literature.

The research on learning communities and student engagement both suggest a complex interaction of factors including the physical, virtual and practical contribute to student success (Zhao & Kuh, 2004). Laird and Kuh (2005) have conducted extensive research based on the National Survey of Student Engagement (Kuh, 2001) and found that tracking student interaction with information technology adds little to existing measures of student engagement. Holley and Oliver (2010) also suggest that even the best designed and most well intentioned e-learning environment cannot effectively address the diverse issues students have as they attempt to progress through university. By the same logic, it is not possible to use a measure of interaction with these environments as an all-encompassing way to predict which students are likely to have problems and which students are effectively engaged with their studies.

In addition to the broader issues around student engagement, LA is limited in terms of the capacity to capture the important distinction between deep and surface learning (Buckingham Shum & Deakin, 2012). Although more time on the learning management system may correlate with higher grades, this may reflect a strategic rather than a deep, lasting engagement with the content and body of knowledge and that is reliant on the contested idea that learning can be categorised cleanly into one of three categories: deep, surface or strategic. Regardless of whether these categories are useful in understanding student behaviour or not, Biggs (1999) argues, in what has become all but a cliché, that the focus for higher education should be on what the student does rather than what the teacher does. Although it is evident that LA is indeed assessing what the student does online, these tools are simply too blunt to be able to separate those students taking an approach that will maximise their chances in the assessment, from those who genuinely engage with the material in a deep and critical way. Although the distinction between surface and deep learning is itself limited for understanding student approaches to learning and that the sum of student learning experiences are far more complex, there is sufficient evidence that deeper approaches to learning lead to better student outcomes (Prosser & Trigwell, 1999). LA is unable to elucidate the student approach to learning, relationships between apparent levels of engagement online and overall student experiences, and is therefore limited as a measure of the process and pathways students may undertake to complete their learning, let alone for higher cognitive processes or ways of being.

The approach currently being adopted in the implementation of LA, with some notable exceptions (e.g. Leece, 2012) is more akin to a behavioural theory of learning than any within the social constructivist realm. Bates and Poole (2003) suggest that, although there is some use for a behavioural approach to learning and much was clearly gained through the work of Skinner (e.g. 1948) and other behaviourists, these approaches to learning do not provide a complete account of what happens in higher education and through technology-mediated, networked learning environments. Laurillard (2002) also points out that a constructivist approach relies on understanding how students interact with the world and with knowledge. The emphasis here is on ‘how’ and not ‘how much’ as appears to be the nature of the data collected using LA.

One notable observation from LA is that the amount of interaction on a learning management system does not necessarily lead to higher grades for all students. Other researchers who advocate the use of academic analytics have also raised this issue. For example, Beer, Clark and Jones (2010) admit that, despite their substantial accumulation of data from their learning management system, there is a large amount of variation between individuals. This variability highlights the major flaw in the argument for academic analytics: not all students interact with information in the same way. The amount of time students spend on the LMS is not an indication of deep or surface learning.

Despite the clear problems with using a behavioural measure for understanding complex social and cognitive processes, LA is clearly not without value. Macfadyen and Dawson (2010) conclude by arguing that the real significance of their study is in the predictive power of LA. Given the current federal government’s agenda of 40% of 25-34 year old with at least a bachelor degree by 2025 (Australian Government, 2009), there is some use for LA in identifying students who are not engaging or are engaging very little with the learning management system because more ‘non-traditional’ students will be entering higher education over the next decade. Based on the observation that this is a simple behavioural measure, it is of concern to see this being touted as a measure of student engagement and success beyond being a blunt indicator. With an increasing emphasis on teaching and learning quality in higher education, this measure is not suitable for assessing quality because it fails to capture a myriad of factors that contribute to student success (see Tinto, 2012). Although there may be benefits in using these tools to identify students who are at risk of attrition, they are currently of little use in ensuring quality and should not be promoted as being able to.

A future for learning analytics

Ultimately, there is a clear need for tracking student engagement as class sizes increase and demands on student and faculty time and attention become more pressing. This argument has been reflected many times in the literature (for instance, James, Krause & Jennings, 2010). LA does provide a tool for assessing a level of interaction and therefore have merit as a broad indicator of students who might be struggling. Despite this, it is evident that LA contributes as much to the understanding of student engagement as did Skinner’s (1948) pigeons to human learning in general. Strict behavioural data such as this lacks the power to contribute to the understanding of student learning in a complex social context such as higher education.

What then is the future of LA in this context of complexity and the need for ensuring quality? We argue that, as with any indicator such as surveys of student satisfaction, LA could become more useful than for managing attrition if it is understood within context. When contextualised within a broader set of indicators, the predictive and diagnostic affordances of LA do indeed provide some ability for understanding student behaviour. As we progress further into the 21st century, it will become less difficult to objectively assess student thinking in ways that are currently prohibitively expensive or unimaginable. The idea of quality learning is going to shift markedly and will necessitate radical revision of the models and learning theories underpinning higher education. We argue that the learning sciences and informatics, in particular, will be at the forefront of these revisions. Our aim with this paper was not to debunk LA as a valid approach to understanding and enhancing the student learning experience, nor was it our intention to single out Macfadyen and Dawson (2010) for particular criticism, we could have just as easily chosen from dozens of other studies on LA. Our hope with this critique is that LA will grow from its current foundation to become part of a larger suite of indicators of quality student learning built on multidisciplinary collaboration, much like that evident in the health sciences. The mining of datasets will continue to provide interesting and useful information about patterns in student behaviour, the future challenge is to better understand patterns in student being, thinking and metacognition, factors that lie at the core of the purpose of a 'higher education'.

Student views on how role-playing in a virtual hospital is distinctively relevant to medical education

Swee-Kin Loke
University of Otago

Phil Blyth
University of Otago

Judith Swan
University of Otago

Virtual worlds have the potential to enact the experiential learning of professional practices in simulated environments. The Otago Virtual Hospital (OVH) is one such virtual world where medical students role-playing as junior doctors make diagnoses and manage realistic clinical cases. To integrate the use of virtual worlds into existing curriculum, their distinctive relevance needs to be determined. A case study was conducted to find out how role-playing in the OVH is distinctively relevant to medical education. Following a trial involving 11 medical students completing the same scenario, three areas of relevance were identified: "making the call"; self-organisation; and "going through the whole process". These areas can provide guidance to educators and staff developers who plan to recommend and sustain the use of virtual worlds in fields such as medical, legal, and management education.

Keywords: virtual worlds, technology integration, medical education

Introduction

> Interviewer: But you guys are busy people, why would you spend two hours in one [virtual] scenario like this?
> Medical student (fourth-year): Can't, can't get it anywhere else. Can't get that same experience. I mean, the [physical] wards are great and you get a lot of time with patients, but you don't get the responsibility. Basically making the decisions.

While medical educators agree on the dangers of allowing fourth-year medical students to make decisions that directly affect a real patient, we continue to debate when and how medical students should learn clinical decision-making safely during their medical education. Avatar-based three-dimensional (3-D) virtual worlds offer a promising way forward: medical students role-playing as doctors could make clinical decisions and live through the consequences of their actions in such simulated environments (Boulos, Hetherington, & Wheeler, 2007). In this paper, we provide empirical evidence on how role-playing in a particular virtual world is distinctively relevant to medical education, with a view to incorporating avatar-based virtual worlds within the current medical curriculum.

The increasing interest to harness virtual worlds for education is reflected in the number of special issues published on the topic in recent years (e.g., de Freitas & Veletsianos, 2010; Lee, Dalgano, & Farley, 2012; Twining, 2010). Accompanying the trend are numerous conferences around virtual worlds for learning (e.g., 5th Virtual Worlds Best Practices in Education Conference, 2012; 2nd Experiential Learning in Virtual Worlds Conference, 2012).

Among the numerous publications on the topic are studies that identified potential uses of 3-D virtual environments by surveying existing teaching practices. The uses range from the delivery of virtual lectures to geographically-disparate students, virtual conversations between foreign language students and native speakers, to the experimentation of gender / ethnic identities. A common use identified by three studies (Dalgarno & Lee, 2010; Hew & Cheung, 2010; Salmon, 2009) is the enactment of experiential learning in virtual 'off-campus' locations (e.g., students role-playing as archaeologists in virtual monumental sites, as lawyers in virtual courts). Experiential learning—'learning by doing'—emphasises students' bodily activity *in situ*, their deliberate reflection on and reconstruction of the experience, thus upholding "the organic connection between education and personal experience" (Dewey, 1938, p. 25). In the same vein, our work around the Otago Virtual Hospital

(OVH) is underpinned by the learning of clinical practice via student participation in and reflection on clinical practice, all within a safe environment.

The OVH

The Otago Virtual Hospital is a 3-D virtual hospital in which medical students role-playing as junior doctors make diagnoses and manage realistic clinical cases within the Emergency Department. Using their avatars, students are able to move around the hospital, communicate with patients, relatives and peers via text chat (see Figure 1 and the two-minute video at http://bit.ly/xZ0Net), perform a 'physical' examination of patients (e.g., clicking on the patient's chest allows students to listen to a series of heart sounds), order laboratory and radiology tests (e.g., CT scan of patient's head), check the results of those tests, prescribe from an extensive range of medicines, and write patient admission / discharge / handover notes. The OVH is built on the OpenSim-based New Zealand Virtual World Grid (http://www.nzvwg.org/).

Figure 1: Medical students role-playing junior doctors taking patient history

Experiential learning is a key modality of medical education within the Otago Virtual Hospital. Many medical educators have speculated that virtual worlds are appropriate for the experiential learning of clinical practice (e.g., Boulos, Hetherington, & Wheeler, 2007; Hansen, 2008; Stott, 2007). However, we recognise that experiential learning can be enacted in multiple ways (e.g., during clinical attachments in brick-and-mortar hospitals) and must give sound pedagogical reasons to recommend the use of virtual worlds over other ways (Loke, in press). Hence, in order to recommend and sustain the use of the OVH in existing medical curriculum, we need to determine its distinctive relevance (Roblyer, 2009).

To ascertain the effectiveness of experiential learning in virtual worlds, many studies have measured the changes in learning outcomes such as level of inquiry (e.g., Ketelhut, Nelson, Clarke, & Dede, 2010) and self-efficacy (e.g., Creutzfeldt, Hedman, Medin, Heinrichs, & Felländer-Tsai, 2010; Henderson, Huang, Grant, & Henderson, 2012). Responding to Kozma's (1994) call to concentrate instead on learning *processes*, we focus here on the differences in the quality of learning experiences. How is the experience of role-playing in the OVH different from existing medical education?

While Gregory et al. (2011) considered this question from the quantitative perspective, in this paper, we provide qualitative empirical evidence identifying the areas where medical students judged role-playing in virtual worlds to be distinctively relevant to medical education. To do this, we interviewed 11 students who had participated in a scenario within the OVH. To better contrast the learning experiences within and without the OVH, we first provide a description of medical education at the University of Otago before we give an account of scenario-based learning in the OVH.

Medical education at Otago

The six-year Medical course at the University of Otago leads to the degrees of Bachelor of Medicine and Bachelor of Surgery. The Year 1 programme (approximately 1800 students) is common to all health professional courses (namely medicine, dentistry, physiotherapy, pharmacy, and laboratory science) and aims to give students a foundation in the biological sciences (e.g., molecular biology, musculoskeletal systems). Interested students then apply to Year 2 of Medicine (limited to 270 places). Other students may seek admission to other degree programmes such as Oral Health, Pharmacy, and Medical Radiation Therapy.

In Years 2 and 3, the focus of the curriculum shifts from the biological sciences towards the medical and clinical sciences. Responding to student calls to increase the day-to-day clinical relevance of the curriculum, the Year 2-3 programme was revised in 2008 to include more case-based learning, clinical skills (e.g., communication skills), and community-based learning in order to increase patient contact (Perez et al., 2009). The case-based learning consists of small tutorial groups reviewing and engaging in tasks related to realistic patient scenarios. These scenarios are used to illustrate the application of medical science to clinical practice and integrate material from other course components. This format is similar to the case-based style of questions found in the end-of-year examination (e.g., http://bit.ly/M0D5fe).

The Years 4-5 see the students divided between three clinical schools of medicine: Dunedin, Christchurch, and Wellington. In each school, the students undertake supervised clinical activities in hospitals, community-based clinics, and general practices (GP). In groups, students will also engage in mannikin-based scenarios for the development of emergency management and clinical skills. During their General Practice rotation, students at the Dunedin School of Medicine participate in simulated consultations with human actors at the Safe and Effective Clinical Outcomes (SECO) clinic (Williamson & Egan, 2011). Their learning experience at the SECO clinic most closely resembles that in the OVH, though student perceptions of key differences will be shared in our findings.

The final year (Year 6) is the Trainee Intern year, a transition-to-practice year where the students are located in clinical practice with supervision from the senior clinical team. They are paid a small stipend and are expected to assume day-to-day clinical responsibility for up to one third of the clinical load of the team. However they remain under the jurisdiction of the medical school, with the focus of their time on education, rather than service delivery (Dare, Fancourt, Robinson, Wilkinson, & Bagg, 2009).

To complement the medical curriculum, we built the OVH to further emphasise authentic clinical practice. Like Butler (2012), we sought to correct the imbalance between knowing and doing (highlighting the latter); but unlike him, we went beyond letting students view virtual world scenarios (i.e., Second Life machinimas) to having students actually participate in such scenarios.

Scenario-based learning in the OVH

The learning design underpinning the OVH is best categorised as scenario-based learning, a form of experiential learning (Hmelo-Silver, 2004) in which “an authentic or contrived scenario forms the basis of all learning, teaching and assessment activities” (Naidu, 2007, p. 251). The scenarios in the OVH were written by the authors of this paper who are practitioners in the fields of education, medicine and nursing. Each scenario is drawn from real-life events and aims to reflect the actual practices of a New Zealand emergency department.

The scenario reported here can be run in the OVH with a minimum of two participants (one playing the patient and another the doctor), hence reducing some of the logistical barriers of gathering enough participants before students can engage in role-playing. Additionally the scenario is flexible enough to include other characters such as senior doctors (e.g., a registrar), nurses, and the patient’s relatives. The patient guides her behaviour based on a pre-written script (e.g., http://bit.ly/o8vUDQ) and can be played by a student or a faculty member.

At the start of the scenario, the junior doctors receive an admission / triage form (e.g., http://bit.ly/rbxI50). Typically, they then apply the patient care framework and take the patient’s history, examine the patient, order laboratory tests, negotiate the treatment plan with the patient, prescribe medications, and finally submit patient admission / discharge / handover notes. Because we aim to mimic actual professional practices, we do not provide any superfluous guidance by, for example, walking the students through the correct steps in patient care.

It is important that advanced level medical students (our target audience) learn to make decisions in authentic and "relatively uncued conditions" (Tishman, Jay & Perkins, 1993, p. 149). Guidance is given via a post-scenario debrief with clinical educators, during which students reflect on their decisions and suggest alternative actions (if any). In experiential learning, this deliberate reflection phase makes experience meaningful (Dewey, 1916). The students are also formatively assessed based on the framework described in Loke, Blyth, and Swan (2012).

We built the OVH in 2010 with a one-year university teaching improvement grant. In order to sustain the use of this virtual hospital, its distinctive role within the existing medical curriculum needs to be determined. Because virtual worlds require relatively higher resourcing (compared to most other e-learning projects), sustainability should be an important consideration (Stewart & Davis, 2012). So, in what ways is the OVH specifically relevant to current medical education?

Method

A case study was conducted to evaluate how relevant the OVH might be to the medical curriculum. All fourth- and fifth-year medical students were invited via email and an in-class presentation to participate in the study. To take part, students registered their interest on a website (http://ovh.otago.ac.nz/) and gave their consent for the results to be published. These documents and processes were part of the successful application for ethical approval by the University's Faculty of Medicine. We carried out the case study with 11 advanced level medical students (Students A-K, comprising 5 fourth-year students, 5 fifth-year students and 1 sixth-year student). These students were selected to have a wider familiarity with clinical practice as well as with the full medical programme. This was the first experience with OVH for all of the selected students.

The students worked on the same clinical case in five groups (of 2-3 students each) during five separate runs. Each run lasted 70 to 90 minutes. The clinical case involved a female patient in her mid-70s, Mrs Gertrude Macfarlane, whose neighbour had found to be increasingly forgetful (e.g., not feeding the cat) and generally unwell (e.g., feverish). In this case study, the patient was played by the same faculty member in all five runs.

After each group had completed their run, a semi-structured interview was conducted with the group and all three authors of this paper. Each interview lasted 25 to 35 minutes. The five interviews had three foci:

1. a group reflection on the decisions made (e.g. "How did you arrive at the diagnosis of UTI (urinary tract infection)?") and learning points (e.g. "What, if anything, did you learn the last 90 minutes?");
2. the nature of the virtual learning experience (e.g. "How did it feel playing house-surgeon?"); and
3. the distinctive relevance of the OVH in medical education (e.g. "What role, if any, can this virtual hospital play in your medical education?").

Although this paper concentrates on the third focus, student views on the three foci were interrelated and were all taken into consideration (e.g. some key learning points signalled areas where the OVH was relevant).

The five interviews were recorded (150 minutes of audio recording in total) and fully transcribed. We analysed the transcripts based on Thomas's (2006) general inductive approach. This approach was chosen because we sought—from our transcripts—to identify themes pertaining to the role of the OVH in medical education. In other words, we were less interested in generating a theory (grounded theory), in exploring multiple meanings in language (discourse analysis), or in describing students' lived experiences (phenomenology).

Each of the authors first read the full transcript in detail. Then, each author created and assigned categories to segments of the transcript individually. As expected, some segments were not assigned to any category because the post-scenario interview had three different foci. The authors then met to negotiate their categories, combining or breaking up categories as well as selecting suitable quotations to communicate the meaning of each category. After reducing the overlap among categories, we arrived at three areas where medical students judged role-playing in virtual worlds to be distinctively relevant in medical education.

In designing this study, we attempted to maximise the "trustworthiness" (Guba & Lincoln, 1989, p. 233) of our findings in the following ways: validity was enhanced by triangulating two sources of evidence (namely students' in-scenario performances and group interviews). Reliability was increased by carrying out five identical runs of the same scenario with five different groups. Indeed, assertions #1 and #3 are supported by evidence from all five interviews, and assertion #2 by four interviews. Insider (tutor) and outsider (researcher) perspectives were maintained and cross-checked throughout the study. Emerging assertions were tested in the entire data corpus and negative examples were actively sought. For example, the assertion that role-playing in virtual worlds was appropriate for developing patient interaction skills was eventually discarded after negative examples were found (e.g., Student K described the text-based interpersonal communication within the OVH as being “a wee bit stilted”).

Findings and discussion

We now present the findings of the study around the three areas where role-playing in virtual worlds was judged to be distinctively relevant to medical education: “making the call”; self-organisation; and “going through the whole process”.

“Making the call”

This category refers to the ability to be fully responsible of the patient and to make clinical decisions that affect the patient. Many students highlighted how the OVH allowed them to actually make decisions and to take action:

> J: Well, you actually *do* the things here. Whereas in the SECO clinic, you write down or you think about what you’re going to do, but you don’t have to practically go and do them. So there’s a bit more here.
>
> H: Yeah, definitely getting to order the bloods was the best. And prescribing things. (...) Yeah, that kind of thing is useful.
>
> E: Most of it, like taking history and knowing what tests to order, is really useful. I mean, we don’t get to order any of that, at the moment.

Indeed, during their medical education, students typically do not get to order any laboratory or radiology tests. A study conducted at the University of Manchester Medical School reported that students on clinical attachments often perceived themselves to be unskilled members of the medical team with no responsibilities (Dornan, Boshuizen, King, & Scherpbier, 2007). While students are involved in clinical decision-making to various degrees, their decisions are always checked by their supervisors to ensure patient safety:

> G: Normally you’d be asked by the house surgeon to fill up the blood form or fill up the X-ray form. In this thing [OVH], (...) you’re actually doing the forms yourself.
>
> H: Generally, what we would do would be, I mean, again it depends on the registrar. In a nice cooperative environment, if they were OK with it, then you could write out the admission notes and examination findings, even though they will want to repeat the examinations anyway. So, they would check it over, I’d probably check with them, and they would check it over and say -
> Interviewer: Have you done that [writing examination findings] before, in your four years?
> H: Kind of.
> I: Yeah.
> H: To a certain extent. But I mean, I certainly wouldn’t be the one making the call. I wouldn’t *want* to be the one making the call.

Allowing students to actually make the call is hence one way that role-playing in the OVH is distinctively relevant to medical education. Dewey (1916), an important advocate for experiential learning, lamented how students often find themselves isolated from professional practice, leading to “the abnormality of the situation in which bodily activity is divorced from the perception of meaning” (p. 141). Based on our students’ views, not being able to make decisions results in at least two disadvantages. Firstly, the students’ learning experience is arguably truncated:

> J: So, when you have like rural GP or something, you get your own clinic, then you get to think a lot. But in the hospital, often, you don’t (laughs).
> K: I know, at my level, often they stop asking the questions at the point where you need to learn most. Like they’d say, “What would you do?” You’d say, “Prescribe fluids.” And they stop. Not how much, which fluids, how long.

Secondly, if students are not allowed to call the shots and to live through the consequences of their decisions, they might find it hard to develop a sense of responsibility toward their patients:

> K: Well, part of it is what supervisor you're getting, how much they try and make sure that you are able to cope with situations and put responsibility on your shoulders. And part of it is making the mental shift yourself. I have to take the attitude with every patient that I see, that I have that responsibility. And sometimes it's a difficult mental shift because you're just thinking, "I'm just a student, it doesn't matter, my decisions don't really count for much." So you've got to physically make that mental shift so that you can prepare yourself for later on.

Similarly, in his anthropological study of medical training in a London medical school, Sinclair (1997) reported that the sense of responsibility is best developed when medical students get to take real action on "'hot' patients" (p. 32) instead of hypothetical action on 'cold' patients (whose diagnoses have already been established by another senior doctor, for example). While the existing curriculum stresses case-based learning, students' responses in 'paper' cases remain purely hypothetical. In a unique way, virtual patients may be perceived as being simultaneously 'hot' and 'cold': student actions result in 'real' consequences (e.g., virtual patient's blood pressure decreases), but the consequences take place within a virtual world. It is important to note that allowing medical students to take full responsibility of a patient is only reasonable because the scenario takes place in a simulated environment:

> Interviewer: Do you think this would be a legitimate experience for you to gain that kind of experience of making decisions?
> G: Yeah.
> F: Yeah, I think so.
> E: It's less scary too, it's not a real patient. If something goes wrong, it's not going to kill them.

The provision of a safe environment makes this learning experience possible. On the downside, two students admitted that, because they were treating a virtual patient, they did take the scenario more lightly. At the same time, their group mate provided the counterexample that their group took a long time to make decisions impacting their virtual patient. Overall, in using computer simulations, we acknowledge and accept the interminable tension between the provision of a safe, virtual environment and the ease of suspending disbelief.

Self-organisation

This category refers to the need to organise one's approach to provide medical care in a fluid yet comprehensive way, adapting the generic patient care framework to the situation at hand. Comparing role-playing in the OVH with a 'paper' case (where all the necessary information to work through the case is laid out), one student expressed the effort needed to adapt his approach instead of simply following the pre-formulated framework:

> B: When you're in the hot seat, like knowing what to do next doesn't come naturally. (…) And when you get a paper case, it does all that work for you already. So there's still a gap in between that [and when] you get in the hot seat. But if you get a paper case, it has already *done* that work for you (…) you're not even tackling the problem, you're just kind of going around it. But whereas in this kind of situation [OVH], you suddenly realise that there's that gap there and you can't get around it except if you go listen and do some of the things.

Indeed, role-playing in the OVH requires the students to first "probe the virtual world" (Johnson, 2005, p. 45) to gather enough information before moving on to the next steps, and not to simply follow pre-determined steps in patient care. Being inherently linear, paper cases channel all students down a single path, doing the work of adapting the approach for the students, and may be limited in developing clinical reasoning (Poulton, Conradi, Kavia, & Round, 2009). The need to adapt one's approach to manage a clinical case was also observed when fourth-year Pharmacy students used a similar (but text-based) role-playing computer simulation (Loke et al., 2011). Adjusting a general idea to the particulars of a situation, as opposed to 'plugging in' what was learned, can be considered as evidence of student *understanding* (Wiggins & McTighe, 2005).

The medical students' varied abilities to self-organise was evident in the number of elements they missed out. During their interviews, students were able to identify missed elements ranging from checking the patient's home situation (Student F), ordering blood tests (Student A), to asking the patient about bowel movements (Student J). To explain their mistakes, many students admitted that they had found it challenging to stay focused during the scenario because of the messiness of the situation: for example, the side-tracking while conversing with the confused patient; the patient's daughter's impatience with their lengthy history-taking; and the simultaneous lines of questioning. Beyond remembering all the appropriate elements in the patient care framework, the students also had to judge whether they had done *enough* before moving on:

> Interviewer: And what did you learn? Or did you learn anything the last 90 minutes?
> K: Just that, things that present very simply, sometimes when you think about them a wee bit more, you start to wonder: "Am I doing it right? Have I done enough?"
> Interviewer: And in this specific scenario, were there things that looked deceivingly simple?
> J: I think yeah, I went from doing the write-up, then I realised I should go back and talk to the patient (laughs). A few things I'd missed, because sometimes, when you're in that spot, you don't think about asking those things [e.g., asking about a possible stroke].

The need to judge the adequacy of one's actions supports our call to reconceptualise medical education as the fostering of doctorly dispositions (Loke, Blyth, & Swan, 2012). As such, learning to become a doctor can be thought of as the 'tuning' (i.e., optimal level, not maximal) of dispositions such as doctorly compassion and responsibility. We speculate that the tuning of dispositions is best learnt through experience and practice. While the medical curriculum focuses on teaching the patient care framework and its components, the OVH provides repeated opportunities for medical students to apply the framework in practice:

> A: I thought that the thing that we never get in med school is the global decision making. (...) What do I do now? Do I call a registrar? I mean, this is the result that you might expect in a dipstick in a UTI, but to take that knowledge and to *apply* it to the care of the patient, from the time they arrive till discharge is a lot different.

The difference between knowing and doing (i.e., application) is also evident when Student C professed to know what a compassionate doctor is like ("Whether you smile, or you're nice to the patient, you introduce yourself, and you ask them how they're feeling"), but then admitted to not having introduced himself to the patient during the scenario.

How one thinks and acts differently *in context* is related to situative theories of cognition. Students used at least three different ways to describe the distinctive moment when they are role-playing junior doctors: "when you're in the hot seat" (Student B); "when you're there" (Student D); and "when you're in that spot" (Student J). They then went on to say how they had behaved or reasoned differently during those in-world moments. This supports the theory of situated cognition which holds that the ways in which human beings think and act are inherently coupled with their environment (Brown, Collins & Duguid, 1989) and that the transfer of learning from educational institutions to the workplace is not straightforward (Lave, 1988).

"Going through the whole process"

This category refers to the need to provide medical care to the patient from the beginning to the end, from the time the doctor first meets the patient until the moment the doctor admits the patient to hospital, discharges the patient, or sends the patient to the operating theatre:

> D: Well, it does help to sort of combine presentation with like, investigation and then treatment. It's always helpful. I mean, back in my mind, I know, "Oh, UTI presents with this, and you give this, and blah blah." But it's still nice to sort of be hit in the face with the simulation.
>
> H: It's nice to tie it all together.
>
> J: It's quite good going through the whole process from beginning to the end, having to think about the tiny, the little things, not just (...) the more straightforward bits. The little aspects of making it actually flow. So quite real, realistic.

Building the "flow" in patient care is related to the second category of self-organisation. In fact, it appears that the open-endedness and the need to go through the whole process are pre-requisites to having students weave their own approach through taking history, ordering investigations, and so on. This continuity is often lacking in the existing medical curriculum. For example, the objective structured clinical examination (OSCE) is a form of scenario-based assessment that is widely used in medical education today. One of its weaknesses is testing students only on "isolated aspects of the clinical encounter" (Smee, 2003, p. 705) in a stations-based structure (e.g., history-taking station, examination station). By going through the whole process, students discover their own strengths and weaknesses:

> J: The whole continuity from beginning to the end, you don't get very much of it. (...) So it's quite useful because it makes you think about what you don't know as well. It sorts of shows what you're not so strong at, so it's good for your own learning. You go back and say, "I need to learn more about this."
>
> A: One thing is a safe way to experience the global decision making. It brings out all sorts of different things that you may not be shown that you don't know. We do an exam in an OSCE, ask a couple of questions from the whole list, a huge list. In OSCE, there are ten stations and 150 topics, so you have no idea what you don't know. What do you do? An ECG? What do you do with the [oxygen] saturation?

The student's last question regarding oxygen saturation is important. Too often, medical students' learning experiences are truncated at the most crucial learning points (as expressed by Student K above): for example, they are asked by their supervisors to measure the patient's oxygen saturation, but not to take any action based on the measurement. Role-playing in the OVH gives medical students the opportunity to provide medical care for a single patient from beginning to the end, requiring them to consider and live through the consequences of their decisions.

Conclusion

We sought to find out how role-playing in a particular virtual world is distinctively relevant to medical education by conducting a case study with 11 medical students. The students identified three areas of relevance: "making the call"; self-organisation; and "going through the whole process". These three areas suggest how role-playing in the OVH can complement as well as extend existing medical curriculum. They can also provide guidance to educators and staff developers who plan to recommend and sustain the use of virtual worlds in other fields such as legal education (e.g., Butler, 2012) and management education (e.g., Pidd, 2004).

While our findings offer pedagogical reasons for us to recommend the use of the OVH within the current medical course, we recognise that curricular relevance is but one of the many factors affecting technology integration. A scoping study on the use of virtual worlds for higher education in Australia and New Zealand revealed that educators should also take funding, support, and other institutional issues into consideration (Dalgarno, Lee, Carlson, Gregory, & Tynan, 2011). Our findings will nonetheless provide pedagogical support for a broader strategy to embed virtual world experiences such as the OVH into medical education.

Impacts of Scheduling Algorithms on Resource Availability

David Lowe
The University of Sydney

Cost and space constraints typically limit the provision of many educational resources, with laboratory apparatus being a common example. This limitation is often ameliorated by utilizing scheduling techniques to manage access over an extended period of time. The specific scheduling algorithms that are used have been shown to have a significant impact on the overall availability of a set of resources and hence the level of access that can be supported. This paper considers ways in which these scheduling algorithms can be enhanced and the resulting impacts. Whilst the results are illustrated through their application to remote laboratory access, the implications are equally applicable to scheduling of access to any constrained resource.

Keywords: Scheduling; Resource Availability; Access; Remote Laboratories; Online Access

Introduction

Laboratories, like many other educational resources, are important tools for supporting student learning whose use is often constrained by financial or logistical constraints. These resources represent a significant financial and logistical investment that can be difficult to develop and maintain, particularly where they involve either significant physical infrastructure or limited software licences (Hofstein & Lunetta, 2004). The resultant limitation in resourcing levels is often dealt with by scheduling student access across an extended time period. This scheduling requires a set of strategies for managing the access and, ideally, optimizing the level of usage.

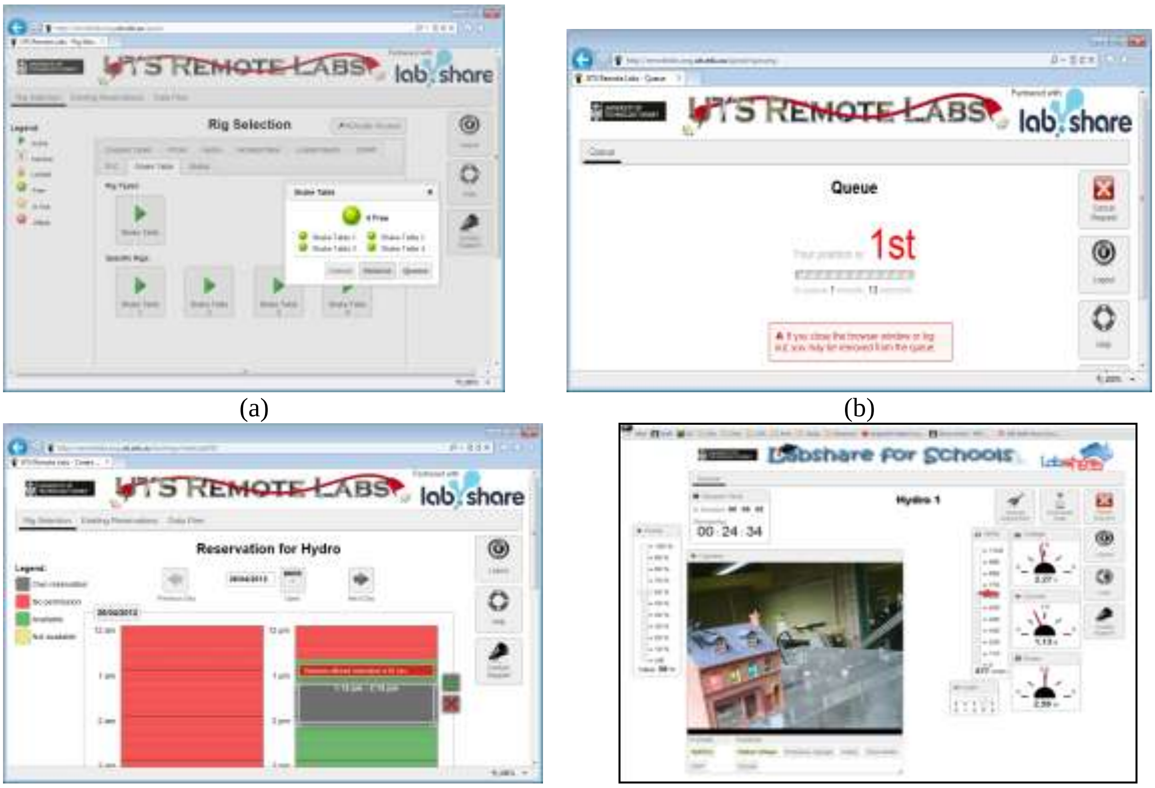
The above issues have been well studied within the context of remote laboratory systems. The rapid evolution and ubiquity of computer and networking technologies and the increasing sophistication of sensors and actuators have led to the emergence of remotely accessed laboratories (or Remote Labs - RLs) as a useful educational tool. Students are able to access, monitor and control physical laboratory experiments across the internet. Various benefits have been shown to arise from their use, including flexibility of access (Gomes & Bogosyan, 2009), the ability to share resources and labs across multiple institutions (Harward et al., 2008; Lowe et al., 2012; Richter, Böhringer, & Jeschke, 2009), security of users, data, and devices (Gravier, Fayolle, Bayard, Ates, & Lardon, 2008), amongst many other benefits.

With this shared distributed use of remote laboratories, scheduling of access has been a significant issue. A number of different strategies have been extensively explored. The two dominant access paradigms mirror those that have been used in many other systems: booking and queuing. In a booking strategy, users are able to select a time slot when they would like to access the system and make a reservation. They return at the specified time and are given access to the system. This is the paradigm that has been adopted by systems such as iLabs (Harward et al., 2008) amongst many others. There are also variations to this technique, such as the scheme used in NetLab (Machotka, Nedic, & Nafalski, 2009) where multiple students can make a concurrent reservation and then share access in a collaborative experiment. In a queuing strategy, such as that supported by Sahara (Labshare, 2010), users request access and are then placed in a queue. They are then provided with access to the first available apparatus that meets their specific request.

Good overviews of these strategies, along with various extensions and hybrids, can be found in the literature (Lowe & Orou, 2012; Orduña, 2011). Typically a booking scheme will be more commonly adopted where the available resources are very limited and student (or teacher, where the lab is being used for demonstration purposes) demand is relatively high – and hence having a confirmed access time is desirable. Conversely, queuing schemes are more commonly used where there is a significant pool of apparatus and students are happy to be allocated any item from the pool. Both of these techniques have benefits and disadvantages. For example, with booking schemes, typically the users will book a session of a specified duration but will very commonly not make use of the whole session. The unused component is then left un-utilised with a resulting waste of capacity. A queuing approach avoids this problem, but does not give users certainty regarding when they may be able to have access.

More recently, the Sahara remote laboratory system has incorporated a scheduling system that allows both queuing and booking to be used in parallel. Figure 1 shows a series of screenshots from the UTS Remote

Laboratory facility illustrating this functionality. The system administrator is able to specify which users can access which scheduling functionality and how different sets of apparatus are handled. For example, with a pool of 6 identical rigs, 4 may be able to be booked or queued, with the other two only available for queued users.



(a) (b)

(c) (d)

Figure 1. Screenshots from The UTS Remote Laboratory facility: (a) Selection of an experimental apparatus and provision of the option to either queue for the next available apparatus, or to make a booking for guaranteed access at a specified time; (c) A user waiting in the queue for access; (c) A user selecting a time slot to make a booking; (d) Accessing a specific experiment that allows students to explore hydro-electric power generation.

Previous work (Lowe & Orou, 2012) has shown that there can be complex interdependencies when both scheduling and queuing are used together. Whilst superficially it may appear that the performance (and hence access for students) would be improved by allowing both scheduling and queuing, analyses of live usage data has shown that significant problems can arise. In particular it was found in this previous work that there would often be significant periods of time where there was a queue of users waiting for access, but apparatus that was not currently in use was not being allocated because there was a later booking and the time available prior to that booking was not sufficient to guarantee the queued users the full session duration to which they were entitled (even if those users would typically not use the full duration).

In this paper we explore the implications of this issue and show how careful adaptation of the scheduling algorithms can lead to significant improvements in the overall resource availability. Whilst the results are discussed in the context of remote laboratories, the findings are generally applicable to the management of access to any restricted resources.

Scheduling Performance Evaluation

To demonstrate the implications of the interplay between booking and queuing systems we developed a Matlab scheduling simulation that emulates the scheduling strategy that is used within the Sahara remote laboratories system. An example of the resultant analysis and visualization is shown in Figure 2. The simulation was validated by testing it with a set of live data drawn from actual usage (277 bookings and 798 queue requests over a period of approximately 7 weeks) and confirming that the simulation allocated the same usage sessions.

To illustrate the implications of the interplay between different scheduling strategies we constructed a sequence of scenarios based around a pool of 3 items of identical experimental apparatus being used by a total of 200 students across a 2 day period (note that the total availability in this period is therefore 3 rigs x 24 hours x 2 days = 144 hours of use). Each of the 200 students will request access to any one of the three rigs, and then when allocated make use of the rig for a random amount of time defined by $T.k^n$, where T is the maximum allowable period, k is a random value between 0 and 1, and n is skew factor that adjusts the likely usage duration. For this evaluation T=1 hour and n=0.5, which gives an average usage time of 0.67 hours, and hence a total usage time of approximately 133 hours –within the available usage time of 144 hours.

Scenario 1 involved all 200 students accessing the apparatus by queuing for access, and making the access request at a random point in the 2 day period. Figure 2 shows the resultant behaviour for one of the 3 rigs. As can be seen there are periods when a randomly greater number of students request access and hence the queue length increases, and there are periods when fewer students request access and hence the queue diminishes. Over the 48 hour period the average queue length is 0.84, there are only a few short period when the queue exceeds 5 users, the average waiting time is 0.61 hours, and the maximum waiting time for any student is 1.76 hours.

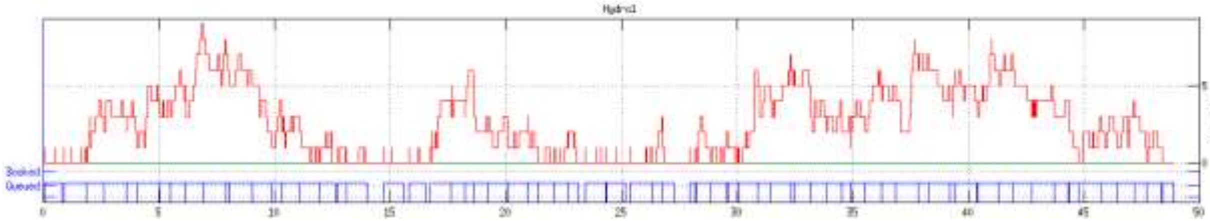


Figure 2. Example of scheduling analysis (Scenario 1) for a hypothetical remote laboratory. The top curve shows the queue length over time (the time axis is in hours) and the bottom curve shows the status of the rig – specifically whether it is idle, in use by a user who queued for access, or in use by a user with a reservation (in this case there are no users who made reservations).

In Scenario 1 no student reserved a specific timeslot, and so no student had a guaranteed access time. To illustrate the consequence of allowing students to make a reservation we considered Scenario 2, where half the students (100) accessed the rigs by making a reservation rather than queuing for access. A reservation will always be for the full time allowed (1 hour) but the users with reservations will still only use the rig for a variable amount of time and then release it back into the pool – potentially to be allocated immediately to a student waiting in the queue. This means that the average usage time (and hence the total usage) remained the same as in Scenario 1. The result of this change is shown in Figure 3. The behaviour in this case is starkly different. Even though the overall requested usage time has remained the same, the existence of the reservations has meant that there are significant periods when rigs are idle, but users are not allocated from the queue because there is less than an hour until the next reservation (because both queued and booked users are allowed to use up to an hour, the system will not allocate them to a rig if there is a reservation within the next hour). The result is an average queue length of 12.55, an average wait of 21.7 hours, and a maximum wait of 31.5 hours. Whilst there are active reservations the queue length continues to grow and does not diminish until after the reservations are all completed. Most significantly, over the first 48 hours, each of the rigs was in use for an average of 29.65 hours, and hence an average of 18.35 hours (38%) of the time was idle despite the existence of queued users.

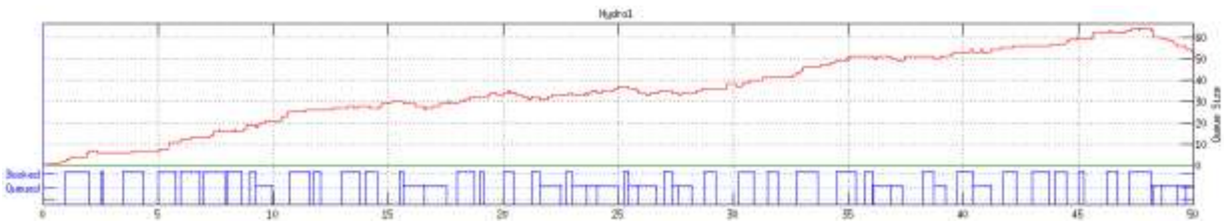

Figure 3. Scheduling analysis for scenario 2. In this case half of the 200 students make a reservation prior to access, with the result that there are substantial unused periods (in between reserved timeslots) and hence a queue that continues to lengthen throughout the period of use.

The third scenario shows how this issue can be addressed by a change in the allocation strategy. The booking and queuing requests were kept the same as for scenario 2, but the allocation algorithm was changed to incorporate two modifications. The first change was to allow a reservation to be delayed by up to a fixed amount (in much the same way that if you have an appointment with a doctor for 3pm, you may be admitted to see the doctor at some time after the reservation time). In this scenario, the commencement of the reservation could be deferred by anything up to 12 minutes. This allows queued users to be more readily inserted into gaps between reservations. The second modification was applied when there were short periods prior to the commencement of a reservation. In this case the shorter period was offered to each queued user in sequence. In the simulation a queued user would randomly accept only if the offered period was longer than the duration of their usage (with the likelihood of acceptance increasing at the offered session got longer). The result of these changes is shown in Figure 4. As can be seen by comparing this to Figure 3, the impacts on the user experience are significant. The average queue length is 1.33 and the average wait time is 1.80 hours. This is longer than the average wait time of 0.61 hours when no reservation at all are allowed and derives primarily from users having to wait for reservations to complete, but is still relatively short. Most significantly, the overall usage level remained almost identical to the case with no reservations and it was possible to make maximum usage of the resources.

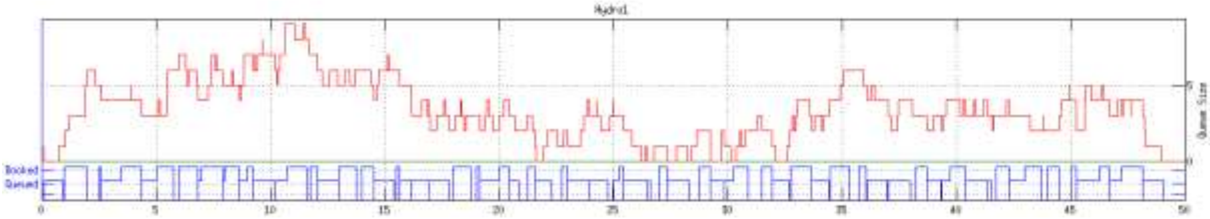

Figure 4. Scheduling analysis for scenario 3, incorporating changes to the allocation algorithm.

Conclusions

This paper has discussed the implication of merging booking and queuing strategies for managing access to laboratory resources. It was shown that if care is not taken a highly suboptimal allocation can result that leads to a significant reduction in capacity and major impacts on the user experience. Conversely, relatively simple adaptations to the allocation strategies can ameliorate these problems and allow the benefits of both queuing and booking to be leveraged.

Remote Laboratories: Sharing Resources and Sharing Expertise

David Lowe
Professor, School of Information Technology
University of Sydney

David Lowe is Director of the Labshare Institute and the Associate Dean (Education) of the Faculty of Engineering and Information Technology at the University of Sydney. Prior to mid-2012 he was the Director of the Centre for Real-Time Information Networks at the University of Technology, Sydney. He has active research interests in real-time control in the web environment and remote laboratories. He has published widely including over 150 papers and three books (most recently Web Engineering: A Practitioner's Approach, McGraw-Hill, co-authored with Roger Pressman). He is also the President of the Global Online Laboratory Consortium.

Intended audience and degree of expertise/past experience required

This workshop is aimed at those who would like to gain an understanding of the role that can played by remotely-accessed laboratories in supporting enhanced access to teaching laboratories - either within the higher-education sector or in supporting science education in K-12. No previous expertise is necessary, though an involvement in laboratory-based SET education and an interest in technological innovation is beneficial.

Statement of objectives for the workshop

Laboratory experimentation is generally considered central to science- and engineering-based education. Logistical constraints can however place significant limitations on the ability to provide and maintain high-quality science laboratory experiences and equipment. One potential solution is the use of remotely accessible laboratories. These laboratories allow students and teachers to use high-speed networks, coupled with cameras, sensors and controllers, to carry out experiments on real physical laboratory apparatus that is located remotely from the student. Research has shown that when used appropriately this can bring a range of potential benefits, including the ability to share resources across multiple institutions, support access to facilities that would otherwise be inaccessible for cost or technical reasons, and provide augmentation of the experimental experience.

This workshop aims to provide participants with:

- An understanding of the challenges associated with supporting laboratory-based science and engineering education;
- The opportunities represented by the use of remote laboratories;
- The pedagogic, technical, and logistical challenges associated with developing, maintaining and sharing remote laboratory infrastructure;
- The opportunity to see a range of remote laboratory apparatus in operation;
- The opportunity to become involved in subsequent follow-up activities and remote laboratory trials.

Detailed description

The workshop will incorporate the following elements:

- A general introduction, by the presenter, to the concepts, pedagogies and technologies of remote laboratories;
- A demonstration of a range of laboratories from the UTS remote laboratories system;
- An open forum Q&A session focused on exploring ways in which remote laboratories can best be utilised.

Learning with technology: theoretical foundations underpinning simulations in higher education

Judith Lyons
La Trobe University

Embracing learning for the future through learning technologies requires a clearer understanding of the pedagogies that inform the simulated teaching and learning strategies used to facilitate student learning. Higher Education e-learning literature often groups educational games with simulation. However, educational simulation attributes are different from games or simulated games with very different aims and objectives within the learning context, which have implications for technology-based learning designs. In order to optimize the use of technology-based simulation this paper presents the theoretical foundations of educational simulation in a disciplinary context. Understanding the simulation pedagogy will assist academics to create technology-based simulated learning environments that highlight the inherent simulation attributes to enable and facilitate learning.

Keywords: Educational Simulations; theoretical underpinnings, e-learning, technology-based

Introduction

A wide variety of educational teaching and learning strategies are available to the teacher in a learning environment. Almost all the possibilities of face to face teaching can be replicated by technology, although some of these strategies can only be represented in a limited manner. Alternatively, some teaching and learning strategies can be enhanced through technology either by presenting alternative approaches to learning (Aldrich, 2004; Gibson, 2004; Milton & Lyons, 2003; Lyons et al., 1998); by extending learning through added dimensions that maybe impossible to conduct in face-to-face interactions (Garrison & Anderson, 2003; Gardner, 2007); or through the use of technology aids, in developing or creating a new understanding of the concepts and knowledge (Lasater, 2007; Lyons & Milton 1999).

Learning by simulation and games enhances the acquisition of new knowledge, and skills, According to Whelan (2005), games if they have the mechanism that promote learning and the development of knowledge and skills will ensure that:

> Games translates into acquisition of new knowledge, transfer of learning, the development of intellectual skills (abstraction, anticipation, strategy-building, problem solving, lateralization, spatial representation function-movement relationship), and the development of behaviour and attitudes (p. 250).

The skills are developed through games and simulation if they provide immediate feedback, interaction, active engagement and participation, control of learning, repeated practice challenge, motivation, dialogue and teamwork (Barnett et al. 2005, and Lyons & Milton, 2002). Sauve et al. (2007), citing others suggests using socio-constructivist pedagogy inherent in games to meet the needs of the new generation learners.

The difference between games and simulation are that games attributes include player, conflict, rules, predetermined goals, its' artificial nature and pedagogical nature, whereas, simulations are based on reality, are dynamic in nature, are simplified representation of reality and has fidelity, accuracy and validity (Sauve et al, 2007). These attributes in simulation promotes basic and complex competency development; promotes interaction, and enables repeated practice in safe learning environment. Simulations offer learning environments which: promotes development of mental models in learners; allows efficiency testing to explain or predict events and outcomes; optimalises discovery of the relationship between variables and divergent approaches; decreases cognitive load using enabling and facilitating functions for learning to take place (Milrad, 2002; Goldenburg et al., 2005).

In order to optimize the use of educational simulation in disciplinary context this paper presents the use of simulations in midwifery education commencing with an emphasis on the use of experiential learning and simulation in the broader educational context. This is followed by a discussion on theoretical foundations of simulations in educational context. The pedagogy of simulations as an educational approach is also described in detail to enhance the learning designs of the future.

Theoretical foundations of simulations as pedagogy

Simulations as learning environments have a long history of use in education and training. Simulation derives its foundation as a pedagogical approach from as far back as the "writings of Aristotle and the practices of Socrates", (Ruben, 1999, p.500). These predate the evolution of learning theories such as experiential learning based on John Dewey's work and later Rogers (1969) experiential learning theories. According to Walter and Marks (1981, p178) simulations may be defined as "models or representations of some facet of the human experience". Jonassen (2000) argues that a computer-based simulation can be a powerful vehicle for learning by applying the critical characteristics of the traditional apprenticeship. It involves placing learners in realistic situations to experience a variety of realistic situations and to learn from them in a safe learning environment without jeopardizing other people. Simulations can present authentic tasks by focusing on the learning knowledge and skills in contexts that reflect the way that the knowledge is used in real life (Brown, Collins & Duguid, 1989). Most effective learning experiences are meaningful, motivating and can be created by goal-driven simulations and scenarios where learners apply the knowledge to solve problems similar to what they would encounter outside the learning experience as highlighted by works of Reeves, Herrington & Oliver (2005).

Simulations can precipitate deep reflection, understanding and behavioural change that results from deep learning. Dewey's central idea of reflective learning and reflective thought as "active, persistent and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and the further conclusions to which it tends" (Dewey, 1910 p6) underpins any basic tenant of simulations. More recent interest in simulation stems from the belief that effective learning results from sustained interaction between the learner and the environment and where there are opportunities through social interaction to reflect on experiences in that environment (Gredler, 2004; Gibson et al, 2007).

Simulations are commonly used in nursing and midwifery education. Simulations do not necessarily need to involve high end and expensive computer platforms as seen in full model simulation such as flight simulators. Research has demonstrated that even low end; low fidelity simulations can be used to provide effective teaching and learning approaches and experiences, (Underberg, 2003; Medley and Horne, 2005). Simulations can involve a broad spectrum of tools that are used in nursing and midwifery education including case reports, scenario discussions, and computer-based simulations. Simulated learning is also used in nursing and midwifery laboratories with standardised patients in simulated clinical situations, virtual reality trainers, mannequins, pelvic models and high fidelity human patient simulators.

Computer simulations are programs that model aspects of real world situations and require decision making or some active input from students. Simulations differ from computer tutorials in that the student learning experience and engagement is by performing tasks in situations that reflects real world situations, (Alessi and Trollip, 2001). These authors further add that the simulated environments are generally a simplification of reality in which the learners can learn procedures, develop an understanding of a phenomenon and experiment with alternative approaches to learning. They encourage students to be more active participants in their learning because they are not controlled by a predetermined sequence of events and can experiment with the situation (Alessi and Trollip, 2001). Computer-based simulations provide a less structured environment in which there is no linearity imposed on the student by the program itself (Gibson et al, 2007) and can powerfully present a wide variety of relevant situations within a compressed timeframe.

In the simulated learning environment student centered goal setting and introduction of the learning activity commences the simulation. Case scenarios or situations can be used to provide the simulation context that requires students to make decisions and solve problems. Questioning may also be used to form the basis of a computer simulation of a real life event, during which the students must decide on the appropriate course of action and respond to the situation (e.g. an emergency procedure or situation). Once the student provides a response appropriate or otherwise, the student action is then used to update the initial simulation which reflects the consequences of students' decision and response. The system updates by providing further details on the incremental case scenarios or situations or it may provide feedback for students to consider and which again may require further student action, reflection and input. The feedback provided also closes the loop of the learning sequence where the system generates a response to student action that represents what may happen in real life.

A simulation can be realistic in terms of its physical and functional components, with the latter component related to the types of situations, tasks or settings included in the simulation. Gredler (2004) offers two major classifications of simulations: the social process simulations and the tactical-decision simulations. Social process simulations, emphasises the interpersonal communication skills and the study of human interactions and emotions in pursuing social, political or ethical goals in realistic situations. In tactical-decision making simulations the emphasis is on problem solving and decision making based on collection and interpretation of information to analyse situations and consequences and to develop strategies to achieve specific goals. These types of simulations create an immersive environment in which learners are encouraged to make difficult decisions and explore the consequences of their decisions.

Alternatively, Alessi and Trollip (2001) identified four distinct types of simulation, namely:

a) Physical simulations

Physical simulations demonstrate how a system works and facilitates the manipulation of system components to alter the output. This type of simulation technology is conceptually linked to what is referred to as system dynamics approach which provides a way to describe and study our complex biological, physical and social world around us in terms of inputs, throughputs and outputs. It enables learners to describe and understand the cause and effect relationships, as well as the consequences 'ripple effect' which may be both intended and unintended effects of an event or decision activity.

Simulations are student-centered approaches to learning that incorporates the cognitive, psychomotor and affective domains of learning, (Nehring et al, 2002; Peteane, 2004). This type of learning is particularly true when sophisticated high fidelity simulators are used to simulate complex functionality and combine the different types of simulation. One such simulation is the 'SimMan' developed by the American Medical Plastics Laboratories. It is a realistic life-sized human model on which students can practice simple procedures such as male urinary catheterization or naso-gastric intubations. Additionally, this computerized simulation is more technically advanced than the "Resuscitation Annie" model used by all health professionals for cardiopulmonary resuscitation and advanced life support training. The SimMan as realistic, complex simulation mimics the human cardiovascular system, i.e. heart sounds and murmurs, central and peripheral pulses an electrocardiograph output including the entire advance cardiac life support arrhythmias. The respiratory system simulates respiratory process including breath sounds, chest movements with air entry and output, carbon dioxide production and oxygen consumption by the body. The simulation also simulates the pharmacological reactive system recognizing and responding appropriately to the action of more than 50 medications on the body. The peripheral pulse oximeter signal represents all the changes in the cardiopulmonary and respiratory system and all inhaled gas mixtures with a focus on oxygen saturation of the body. The simulation also shows blinking eyelids, papillary dilation and reaction to light while 'voice grunts' simulate neurological responses of the patient. These types of computerised clinical simulations provide learners with examples and scenarios of actual clinical events that enable learners to make decisions on real-life care situations. It allows the students to practice by changing the input variables as well as outlining the procedure they would use in the resuscitation process when they are placed in a situation of attending to a collapsed patient. Feedback is provided in response to their action where students can analyse what has happened as a consequence of what they have done and make further decisions to deal with the resultant situation.

In midwifery education it seems no such advanced simulation exists but a commonly used model is the 'Resuscitation Doll' which is the equivalent to the 'Resuscitation Annie' model used by all health professionals for cardiopulmonary resuscitation and advanced life support. The resuscitation doll is used in the resuscitation training for babies and small children. The simulation combines the situation of a collapsed baby with the steps in the procedures of resuscitation that enables students to apply these skills and gauge the effectiveness of ventilation and cardiac compression. Another example is the Pregnancy Simulator Learning Package (PSLP) which simulates the human reproductive system during pregnancy and the complex clinical decision making and problem solving skills used in health and pregnancy assessment by health professionals (Lyons et al, 1998; Dow, 2008).

b) Process simulation

These are simulations in which the rate of physical process is changed. This is also referred to as dynamic modelling which allows the slowing down of or the acceleration of the physical process to enable learners to easily evaluate the individual components (Conrick, 1998). This type of simulation is commonly used across many discipline areas and allows students to view an event in a reasonable timeframe for example cell division and other physiological and neurological processes used in health sciences. In midwifery, a non-computerised plastic model of the pelvic torso is frequently used to simulate labour and the birth process showing the descent and rotation of the foetus as it negotiates the birth canal. Students are able to visualise what happens during the birth process paying particular attention to the relationship of the fetus to the landmarks in the pelvis enabling them to practice what they are required to do to assist the birth of the baby.

c) Procedural simulation

Some tasks require a certain sequence of actions to be performed to achieve an outcome. The procedural simulations ensure that students follow the correct sequence of steps in order to achieve the desired outcomes. Students also learn the consequences of not performing the correct procedures. For example, in the resuscitation of a collapsed patient, the student is able to assess the situation, identify the underlying problem and initiate the appropriate patient care and management. If the collapsed patient is not breathing and does not have a pulse then the resuscitation procedure is initiated, which is to: a) Call for professional assistance as resuscitation cannot be sustained over a period of time by just one person. b) Institute the 'ABC' of resuscitation i.e. assessing and managing the airway, breathing and cardiac compression to treat the patient.

In midwifery, procedural simulations focus on how to perform midwifery practice skills hence rubber arms are used for teaching intravenous insertions and giving intravenous injections. The rubber vaginas are used to assess cervical dilatation during labour and rubber perineum together with surgical instruments are used to teach cutting and suturing of episiotomies and perineum care after the birth of a baby to mention a few. The PSLP emphasises the procedure of abdominal palpation and how to perform this procedure in terms of where and how to place the examining hands on the abdomen to obtain accurate findings from palpation. The added advantage is that the simulation provides the opportunity to demystify the age old tradition of following a certain set of steps as it allows the students to conduct and practice each palpation skill on its own and in any order with appropriate feedback to guide the students in seeing the relationships and the rationale for each palpation movement.

d) Situational simulation

Situational simulations are presentations which could be a clinical scenario, a conflict situation or an emergency situation where the student makes decisions to respond to the situation and develops strategies to rectify the situation as they would do in real life contexts. The provision of a real life situation gives learners a sense of immediacy and involvement where time and the chosen response matter to the successful outcomes. A wide range of 'what if' situations can be simulated often using complex programming and branching to allow for the variation in the situation, patient responses, student actions and decisions to solve the problems. In these types of computer simulations feedback provided makes students reflect on their responses prior to continuing or feedback provides the opportunity for students to re-assess their care management and adapt their actions appropriately to remedy the situation. The PSLP through its case studies simulates the variations in assessment findings and simulates the complicated obstetric conditions and emergency situations that a student may not have the opportunity to experience in real life.

Summary

This paper presented simulation pedagogies as educational approaches to designing teaching and e-learning activities. It has a review of current types of simulations in use with specific reference to midwifery education. Simulation pedagogy provides a framework for successful analysis, design, development, and implementation of e-learning that entails simulation attributes to facilitate technology-based learning. Similarly, teaching, assessment, and administration of e-learning can be strengthened though a process of capacity building that is able to release the full potential of embedded learning technologies if the theoretical underpinnings of simulation are understood and applied in the creation, design and development of simulated learning.

Future-Thinking Flexible Learning Development: A Design Approach for Sustainable Change

Claire Macken
Flexible and Online Learning Development Projects
La Trobe University

John Hannon
Curriculum, Teaching and Learning Centre
La Trobe University

Can you imagine the student's experience in higher education beyond 2020? How will teaching approaches have changed? How will learning technologies play a role in the 21st century student? In higher education, institutions will need to be future focused. So far, institutional change in the use of learning technologies has been dominated by an applied or pragmatic focus that persists despite the increase in uses of constructivist pedagogies and the potential of the read/write web, or Web 2.0. This paper proposes a new, future thinking and sustainable approach to flexible learning development. This approach engages with factors that are often ignored in applied design approaches to learning technologies, including the change management problems associated with introducing flexible learning into higher education institutions and conflicting institutional practices when using technology systems. The sustainable design approach proposed in this paper is referred to as 'FOLD': Flexible and Online Learning Development, as introduced at La Trobe University, Victoria, Australia.

Keywords: flexible learning. sustainable, change, practice, design

Problems of Change Management when Introducing Flexible Learning

In higher education, institutional statements often present 'flexibility' as a unified, coherent entity. However, there are distinct institutional actors involved in its implementation through the organisation, and differences are likely to emerge in practice. Fragmented approaches to curriculum design can miss the opportunities provided by new practices in teaching and learning, as well as the learning opportunities offered through new technologies. The literature on learning technologies and institutional change offers many accounts of a persistent gap between institutional strategy and practice, and a history of costly and dubious outcomes (Russell, 2009; Gunn, 2010; Conole, 2010).

Collis and Moonen (2002) describe flexible learning as a "complex phenomenon" that is "expressed in terms of only four components: technology, pedagogy, implementation and institution" (p. 217). With the ubiquitous presence of learning technologies in universities, the term 'flexible learning' acts as a strategic descriptor that draws together different parts of the organisation that then take greater interest in the hitherto academic concerns of teaching and learning. In practice, these components offer disparate vocabularies and legacies and involve many different roles within an institution,. The consequent tensions can result in a discourse of flexibility and the application of learning technologies that fail to speak to pedagogical practices.

One approach to this structural complexity of flexible learning is an applied focus to flexible learning design. Applied design approaches, according to Bennett & Oliver (2011), tend to be limited to "practical, instrumental concerns" (p. 187), and they tend to confine their scope to local settings of curriculum, students, technologies and teaching staff. This pragmatic approach, or "use-inspired design research" (Reeves, Herrington & Oliver, 2005), the authors argue, tends to an uncritical process in which learning technologies are defined as a narrow field closed off from ideas and approaches from other disciplines.

This applied approach to flexible learning design is also problematic because it is not necessarily sustainable. The approach misses the broader factors shaping institutional flexible learning featured in educational research, such as "the economic concerns of government; second, the commercial interests of information technology vendors; and third, the managerial preoccupations of university administration" (Selwyn, 2007). Where technologies become a key part of learning, competing institutional practices come into play (Hannon, 2012), and a design that reflects a lack of alignment between learning goals and other institutional actors will be unable to put into place the conditions for sustainable use of learning technologies.

FOLD as a future thinking and sustainable approach to flexible learning development

This paper describes ‘FOLD’, an acronym for ‘flexible and online learning development’ in higher education, and a process for sustainable future-focused change management for flexible learning in the curriculum. FOLD has the purpose of designing or redesigning subjects or courses to include blended, online or flexible learning components of design. FOLD is currently being implemented for course and subject design at La Trobe University, Victoria, Australia. FOLD is a University-wide change management project with the key objectives of:

1. Developing and leading a University-wide project that designs or renews strategically important subjects and courses at La Trobe to include flexible, online and/or blended learning approaches.
2. Establishing policies and procedures that embed flexible, online and/or blended learning design in new and revised courses as part of course quality lifecycle review.
3. Providing expert advice and practical assistance at University, Faculty and School levels on flexible and online learning options, including a toolkit, guides, manuals, materials and professional development for academic staff.
4. Advising and informing University academic staff and managers on current research trends and best practice in flexible and online approaches, including learning futures, new delivery partnerships, models and technologies.

The FOLD delivery model envisions single subject design to full course redevelopment, partnering professional educational designers with academic content experts, involving both Central and Faculty teams, for a holistic and collaborative design approach harnessing different areas of expertise and support. Curriculum delivery designs include approaches for multi-campus flexible delivery strategy to ensure sustainability, equity and efficiency across the university campuses. The collaborative team for FOLD can consist of several, or all, of the following roles:

- Flexible learning facilitator / designer – expert in T+L to facilitate subject design
- Curriculum and academic developer
- Academic/s involved in subject teaching + Faculty T+L expertise
- Production and curriculum resource development adviser
- Technologies expertise– For example, Personal learning systems developer or virtual classroom expertise etc.
- Library and digital resources expertise – Faculty liaison librarian
- Language & learning expertise – Faculty academic, language and learning liaison
- Co-curricular and student engagement expertise– For example, work integrated learning, leadership programs, study abroad programs

Assembling sustainable practice

Each FOLD project through this approach exemplifies a program that emerged from a distinct set of negotiations and contingencies involving factors and participants that extended beyond the local teaching and learning setting. The outcome of the FOLD process did not result from the application of a forward-looking design process, but from intensive engagement with an existing state of affairs and a ‘bottom up’, ‘top down’ approach for the purpose of institutional engagement with flexible delivery design.

For example, one FOLD Project in 2012 was development of a resource for clinical educators’ engaged by the University to supervise Physiotherapy students. The project commenced with two intensive workshops with the teaching team, and involved a number of design staff including LMS expertise, a graphic designer and library liaison. The process involved drawing together existing disaggregated practices and resources comprising *ad hoc* one to one arrangements, and establishing a central professional development website with guidelines and resources for clinical educators, that were aligned with program goals and external requirements. The effort involved in the project was distributed to the team for assembly and quality checking. The resulting “Clinical Educators’ Resource Kit” is an instance of sustainable practice since it can be used by many participants, it contributes to a critical component of the program, and requires minimal maintenance to keep updated.

Figure 1: Sample FOLD project

For flexible learning projects to qualify as a 'FOLD project', they must be organised around the FOLD principles and process. This includes collaboration and ownership by discipline teams, alignment with strategic goals and support by Faculty, facilitation and support by curriculum and learning technology expertise. FOLD projects do not implement a pre-designed plan, rather, projects are fit for purpose, assembled to match discipline needs, with the available University resources. This approach, then, engages with the messy reality of specific issues facing a program or course - managing change by making connections, negotiating arrangements, organising places, times and resources. From this process, plans and designs emerge, but as an activity in response to the settings rather than a template to be applied.

Future-focused and sustainable flexible learning

The assembly approach to flexible learning design described above is to ensure that the FOLD process is sustainable and future-focused. FOLD brings a focus on spatial and temporal arrangements of teaching and learning practice. It attends to the embodied activity entailed in the arrangements of activities, actions, goals and practices that constitute processes such as "learning" and work.

This approach follows Stepanyan et al.'s (2009) practice-oriented definition of sustainable e-learning, framed within education values and oriented to practices with learning technologies. According to Stepanyan et al., sustainability is the property of e-learning practice that evidently addresses current educational needs and accommodates continuous adaptation to change, without outrunning its resource base or receding in effectiveness (p.10). FOLD adopts the notion that sustainable education is better able to bridge the gap between practices of teaching and learning and institutional strategies for change (Stepanyan et al. 2010; Gunn 2010). It is able to scope uses of learning technologies beyond simply local innovations (Gunn 2010), and offers an understanding of flexible learning in terms of teaching and learning practices rather than institutional directives. Hence, sustainability provides a more grounded basis for embedding a learning technology change process.

Conclusion

The notion of flexible education is "firmly entrenched" but a contested term in higher education (Tucker & Morris, 2012), that tends to be loosely defined, particularly in institutional policy statements, and generally presented uncritically as an obvious solution to problems facing higher education (Bigum & Rowan 2004; Deakin University 2009, p. 12). Hence flexible learning tends to be tied uncritically to institutional operations, producing a top-down institutional flexible learning environment, resulting in poor take-up and transmissive pedagogical approaches.

This paper explains a future-thinking flexible learning development approach to address the critical need to engage with broader institutional factors shaping flexible learning. At La Trobe University, Victoria, Australia, FOLD is a flexible and online learning development approach to embed flexible learning in the curriculum. This holistic design approach focuses on the various aspects of the curriculum, including students, teaching staff, content, resources, technologies and learning activities. This 'assembly approach' to design organises the connections of networked learning, including Faculty goals, learning locations, schedules, technologies, external drivers of curriculum, such as professional bodies, viability, funding, politics, alliances. FOLD offers an example of a shift from the "ought" of plans & designs to the "doings" or enactments. Plans and designs, therefore, are considered as another activity (Suchman 2007). We argue that the FOLD demonstrates an approach to sustainable flexible learning that can disseminate across institutional disciplines and settings, and embed local, bottom-up practices that are capable of stabilising and persisting.

Relevant, current and sustainable digital strategies to prepare future teachers to lead e-learning

Julie Mackey

This paper describes how one teacher education programme integrates multiple strategies to ensure graduating teachers are prepared to lead e-learning in New Zealand classrooms. Contrary to recent criticism, initial teacher education (ITE) provides strong leadership in the innovative use of e-learning and digital technologies, and emphasises the digital capabilities, knowledge and confidence students need to succeed in their teacher preparation and beyond. This paper reports on the coherent range of strategies employed by one university that model good practice in blended online learning including: a social networking strategy to develop core digital skills; peer mentoring; the use of e-portfolios and Web 2.0 tools; as well as the integration of advanced e-learning pedagogies for course work. Evidence from several projects supports the claim that initial teacher education is developing essential e-learning leadership for future teachers and providing valuable professional leadership to the wider education sector.

Keywords: preservice teacher education, e-learning, e-learning leadership.

Introduction

Initial teacher education providers are acutely aware of the need to deliver high quality programmes and to ensure graduates meet the New Zealand Graduating Teacher Standards (NZGTS) (New Zealand Teachers Council, 2007), including the expectation that, in using "professional knowledge to plan for a safe, high quality teaching and learning environment," beginning teachers will "demonstrate proficiency…in ICT relevant to their professional role." Demonstrating such proficiency is both broad and complex, requiring beginning teachers to understand the technological and pedagogical implications and potential of a constantly evolving field. Recently criticism has been leveled at New Zealand teacher education providers: (a) suggesting they are not preparing beginning teachers to confidently and competently embrace e-learning; (b) raising doubt as to whether ITE providers are using current technologies themselves; and (c) suggesting that ITE providers are failing in their professional and intellectual leadership in the e-learning arena (Newman, 2011). This paper refutes those three allegations and provides evidence from one university where e-learning leadership influences pedagogy and practices throughout ITE and postgraduate programmes. The authors doubt they describe an isolated example of professional e-learning leadership in Australasia and intend this paper to garner response and collaboration from other teacher education providers, and to raise the profile of e-learning in ITE and its value for schools today.

The main evidence for this paper is drawn from an award winning three-year Bachelor of Teaching and Learning degree which underwent significant redevelopment in 2010 and 2011. The deliberate, purposeful and coherent use of digital technologies and culturally responsive e-learning pedagogies (Hunt, Needham, & McMurray, 2012) are interwoven throughout the programme to ensure beginning teachers have experienced learning within a blended e-learning environment and have the opportunity to develop their own capability and confidence. After briefly considering the literature, evidence is provided from this and associated programmes.

Literature

There is no doubt that future teachers need to be well equipped with the skills, knowledge and understanding to effectively integrate digital technologies into classroom programmes to support learning and enhance student outcomes (Davis, 2010). One of the challenges facing ITE is how to develop the capability and confidence for beginning teachers to lead e-learning in pedagogically effective ways with rapidly evolving technology and

changing contextual demands (Gillard, Bailey, & Nolan, 2008). ITE students enter their studies with varying degrees of technological experience (Wassell & Crouch, 2008) and, like the general population, while most are adept at social networking and the use of mobile technologies "they may still be neophytes when it comes to understanding how to use them in purposeful and educationally oriented ways" (Wright, 2010, p. 19). Furthermore, a student cohort may display considerable diversity in their prior technology experiences, attitudes, and capabilities, and academic staff have a tendency to over-estimate students' abilities to appropriate their digital skills and devices to support formal learning (Beetham, McGill & Littlejohn, 2009).
The challenge for ITE is to recognize the diversity of prior experience and to develop, not only technological understanding and skills but more importantly, an understanding of pedagogically appropriate ways to integrate e-learning to promote student engagement and achievement (Blankson, Keengwe & Kyei-Blankson, 2010). Mishra and Koehler's (2006) technological pedagogical content knowledge (TPACK) framework is particularly helpful for understanding and guiding the complex choices teachers face when selecting appropriate pedagogies and technologies. The application of TPACK in teacher education contexts is well accepted and well researched (for example, Abbitt, 2011; Albion, Jamieson-Proctor, & Finger, 2010).

Engaging prospective teachers with learning experiences that will enhance their skills, as well as their beliefs, perceptions and confidence in regard to applying ICT is likely to influence their technological pedagogical practice in schools (Divaharan & Koh, 2010). Therefore, it is critical that teacher educators model appropriate pedagogies (Grossman, 2005) and that technology is used in context "as a tool for learning to teach, rather than content to be learned" (Wassell & Crouch, 2008, p. 214).

Effective e-learning is central to one award winning programme

Following a comprehensive review of the University of Canterbury Bachelor of Teaching and Learning degree a redeveloped programme was launched in 2012. As Hoban (2005) advocates, the process was founded on a research-informed conceptual framework. The conceptual framework: focuses on the educational needs of children; prepares graduates to meet the NZGTS; and clearly articulates a philosophy of teaching and learning. Substantial changes were made to the structure and content of the programme, and a decision was made to replace the existing dedicated ICT strand with an embedded and holistic approach to digital technologies and e-learning. It was clear that a detailed implementation plan was required along with support strategies for staff and students to ensure that digital capability and e-learning were not left to chance. The following discussion provides evidence of the multiple ways e-learning enables the delivery of the programme in three modes for campus, regional and distance students, and the strategies employed to ensure graduate teachers are prepared to lead e-learning.

Preparing beginning teachers to confidently and competently embrace e-learning

A survey of students in their first year of study (n = 110), along with staff interviews, confirmed that generally students were confident in their ability to use email, social networking, mobile technologies, and common features of productivity software. However, they were far less confident with more advanced software features, or tools such as RSS feeds and aggregators (Mackey, Davis, Morrow, Gikandi, & Dabner, 2012). Of concern were the relatively small group of students who appeared to have little or no digital confidence. Strategies were clearly needed to ensure basic digital capability for students to successfully engage in the e-learning experiences integral to their study. In addition to a formal induction to the learning management system (LMS) and e-portfolios, three related initiatives focused on developing capability and providing support for students. These were (1) the recruitment of a peer mentor team; (2) an online self-evaluation and collaborative learning site based on social networking principles (developed within PeerWise, http://peerwise.cs.auckland.ac.nz with assistance from the peer mentors); and (3) the implementation of an LMS e-learning support site providing a central resource area and a Q&A forum. The focus of these initiatives is not on pedagogy per se, however responses and resources are contextualised to teaching and learning scenarios, for example how to record a mihi using podcasting or Web 2.0 tools. As reported elsewhere in more detail (Mackey, Davis, Morrow, Gikandi, & Dabner, 2012) the peer mentors provide the vital link between requests for help and the two online environments, and are largely responsible for the content and ongoing development of the PeerWise site.

Extensive use is made of the Moodle-based LMS for campus, regional campus and distance students as all three cohorts share common course sites, assessments and activities. Schools are increasingly adopting blended pedagogies and these future teachers will have valuable first-hand experience of blended learning based on collaborative and constructivist pedagogies. In 2011 the college switched from Mahara MyPortfolio (Tertiary) to MyPortfolio (Schools) to enable students and staff to use e-portfolios in the same environment and alongside schools. This provides future teachers with experience using the same platform as many New Zealand schools, and the ability to interact with associates, provisionally registered teachers, and school leaders.

Programme initiatives using current technologies

In conjunction with the strategies to prepare students to engage with technology in their professional learning, there has been a purposeful focus on how to integrate the appropriate use of current technologies and e-learning into all courses informed by TPACK. For example, staff have been encouraged and supported through organised professional development, teaching showcase events, and one-to-one mentoring to:

- model blended e-learning pedagogies using the LMS, AdobeConnect, interactive whiteboards, and e-portfolios for students studying in three modes;
- embrace Web 2.0 tools for collaborative work, class activities and assignments;
- integrate appropriate digital content from relevant sources (eg Te Kete Ipurangi, DigiStore);
- adopt e-assessment strategies using the LMS and/or e-portfolios;
- establish virtual connections with teachers, schools, subject associations and educational leaders;
- develop learning networks that include experts from related industry and real-world contexts.

There are many examples of innovative e-learning including the use of AdobeConnect to support interactive workshops for campus, regional and distance students; Web 2.0 tools like VoiceThread for students to record and provide feedback on multimedia assignments; college iPads and personal ‘bring your own devices’ (BYOD) for curriculum activities; existing as well as staff and student-created video; and a specially-designed e-learning lab where up to 81 students can work collaboratively in small groups around shared computers. MyPortfolio is being used increasingly by staff and students for professional learning and development including teacher registration processes. The evidence demonstrates that teacher educators are willingly adopting emerging digital technologies to support ITE programmes and provide students with a range of e-learning experiences.

Professional leadership in e-learning

Surprisingly, Newman (2011) also suggested that there was a perception that ITE providers were not providing intellectual and professional leadership in the e-learning arena. This is difficult to understand given that members of this institution (and undoubtedly those in other institutions too) have actively provided e-learning expertise and leadership nationally and internationally in the last few years including, for example:

- Leading the Research Strand of the ULearn 2010 and 2011 conferences attended by over 1500 teachers.
- Editing a special edition of the Computers in New Zealand Schools Journal (December 2011).
- National and international conference presentations including ULearn, Distance Education Association of New Zealand; Society for Information Technology in Teacher Education, Australasian Society for Computers in Learning in Tertiary Education.
- Contributing actively to the Greater Christchurch Schools Network and associated activities for the rebuild of Canterbury education (including hosting a Think Tank for educational leaders).
- Hosting webinars to ensure that the New Zealand education sector has access to visiting world experts in e-learning (including for example in 2012 so far, Prof. Lynne Schrum, Dr Elaine Hoter, Prof. Paul Bacsich).
- Supervising and conducting research related to current issues in e-learning, virtual schooling, and related areas (for example Stevens, 2011; Zaka, 2012), including school research partnerships.
- Providing professional development and leadership to virtual schooling clusters and local schools including a Postgraduate Diploma in Education (endorsed in e-learning and digital technologies).
- Representation on national bodies for example the Tertiary e-learning Reference Group; Ultrafast Broadband in Schools Governance Board.

In addition, the academic staff teaching the BTchLn (Primary) degree were presented with the Distance Education Association of New Zealand Award in 2012 for their outstanding effort in leading learning through the earthquake interruptions of 2011; an effort which was enabled and sustained through the innovative and extensive use of e-learning pedagogies.

Conclusion

This brief discussion illustrates that ITE providers are well positioned to prepare the next generation of teachers, and that contrary to some perceptions, colleges of education are innovative, progressive leaders in their adoption and advocacy for e-learning. The authors seek further evidence from other programmes in Australasia to raise awareness of the vital role that ITE plays in developing and leading e-learning. The presentation will invite discussion to promote research collaboration and a higher profile for e-learning leadership by teacher educators.

Designing an online activity for collaborative language learning

Mauricio Marrone
Macquarie University

Lilia Mantai
Macquarie University

Marika Kalyuga
Macquarie University

Engaging students when learning new vocabulary, building an environment that allows for collaboration and teamwork and providing approaches towards learning via problem solving is not an easy feat in teaching a second language. To have an activity that incorporates these three strategies in one for both face-to-face and geographically dispersed students can be challenging. This paper describes how an online activity in Moodle linked to the glossary module allows students to possibly learn vocabulary more efficiently, quicker and in a more engaging way.

Keywords: Collaborative learning, Moodle, language learning.

Introduction

The purpose of this paper is to analyse the design rationale, development and implementation of picture-based online activities for second language (L2) vocabulary learning. The paper provides a short overview of research on effective learning processes and describes online activities for L2 vocabulary acquisition that implement visual images as learning tools. Most students find many vocabulary-teaching methods are at worst painful (Krashen, 1989). Common questions addressed in research on L2 acquisition are concerned with efficiency of traditional teaching methods, long-term retention of vocabulary taught, as well as student motivation and engagement.

Alavi (1994) proposes that there are three attributes for effective learning processes in the area of cognitive learning theory:

1. Active learning and construction of knowledge
2. Cooperation and teamwork in learning
3. Learning via problem solving.

A strategy that covers all of these three attributes is collaborative learning. The term collaborative learning was first introduced by Piaget (1926) and later progressed by psychologists Johnson and Johnson (1975) and Slavin (1987). The benefits of collaborative learning, as summarized by Cecez-Kecmanovi and Webb (2000), are: better motivation (Johnson et al., 1981), higher test scores and level of achievement (Dansereau, 1983), development of high level thinking (Slavin, 1987) and higher student satisfaction (Sharan, 1990). With the introduction of technology in education, the term Computer-Supported Collaborative Learning (CSCL) was fashioned by O'Malley (1995). It can be defined as "the learning sciences concerned with studying how people can learn together with the help of computers" (Stahl et al, 2006). Resta and Laferriere (2007, p. 67) describe it as "interactions take place among students using computer networks to enhance the learning environment […] to support asynchronous and synchronous communication between students on-campus as well as students who are geographically distributed".

Case study

As one of the few Australian Universities, Macquarie University has a Department of Russian Studies. Students of Russian wish to have more interesting and engaging activities to learn new vocabulary outside their classroom environment as opposed to traditional pen and paper drills. Highest priority is given to quick and efficient acquisition of vocabulary to allow for conversation in L2 at early stages. This part of language acquisition is perceived to be the hardest by students, as it requires perseverance, patience and time.

This paper introduces a game-like online activity that was designed to facilitate efficient vocabulary learning. The implementation of Moodle, the new Learning Management System (LMS) at Macquarie University in

Semester 1, 2012 created an opportunity to make changes to the current course design. The new online activity was designed to bring together various multimedia elements essential for vocabulary learning, such as sound, images and texts and helps students to better recall meanings, pronunciation and grammatical properties of foreign words. For instance, the student will be able to hear the pronunciation of the words outside the class, as it automatically links to text-to-speech online service. Further, the online activity corrects their errors instantaneously and provides immediate feedback on their learning progress.

It uses the common principle of matching foreign L2 words with familiar L1 words to help memorising a foreign language vocabulary. It resembles a flashcard-learning pattern as newly added words circulate through the exercises. Oxford and Crookall (1990) discovered that flashcards is one of the most practised techniques by students to memorise new foreign vocabulary.

The online-activity allows choosing between different types of exercises: word to translation or explanation of grammatical properties, word to image/picture, word to audio/pronunciation and image/picture to audio/pronunciation. The exercises are directly linked to the glossary module, so whenever a new entry is added to the glossary it will show up immediately in the exercise.

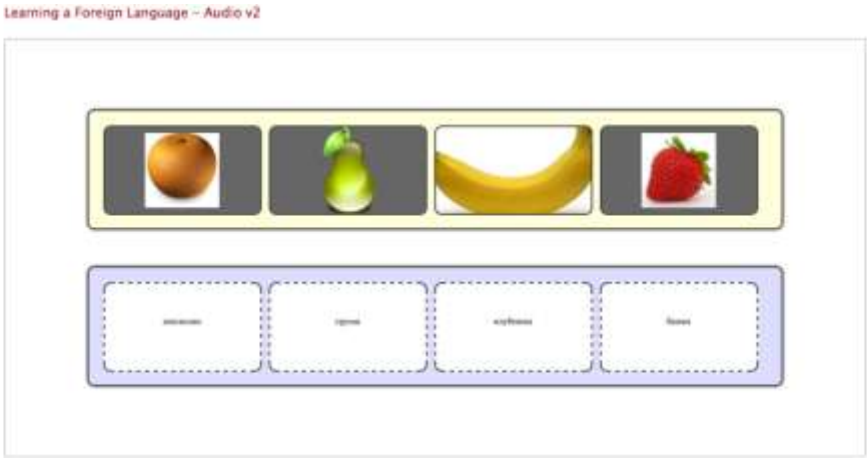

Figure 1: Screenshot of online-activity

The activity presented in this paper then feeds from the information entered in the glossary. The glossary in Moodle enables students to add words, their definitions and images and all entries are visible to all unit members. It also allows for students to comment on each other's contribution to the glossary, permitting them to leave feedback, request further information about a word or even correct the spelling. The convener of the unit is able to decide if he wishes to approve the words entry in the glossary or if all words should be automatically made available to all students. One of the benefits of adding words to the glossary is that if a word is listed it appears on other pages within that Moodle unit. These words are automatically highlighted and when clicked the user is directed to the glossary entry, allowing the user to review the meaning of the word. Entering words to the glossary is simple, as it only requires a word or concept, a description and the option of including an image.

The use of multimedia in second language learning, in particular the presentation of information in various formats (text, audio, graphics, animation, video), has become the subject of much debate amongst researchers and educators. Concerns often raised are whether learning foreign languages would be more effective when visual images are employed. Various studies have been undertaken to assess the impact of visual images on language learning (e.g. Carpenter & Olson, 2012; Chun & Plass, 1996b; Herron, Hanley & Cole, 1995; Omaggio, 1979; Yeh & Wang, 2003). Computer-assisted language learning literature mostly focuses on the impact of pictorial glossing on incidental (e.g. through massive reading or listening) second language vocabulary acquisition rather than on intentional vocabulary learning. Commonly held views are that visual images facilitate reading comprehension (Chun & Plass, 1996b; Herron, Hanley & Cole, 1995; Omaggio, 1979) and that the presentation of foreign words with their pictures, in addition to native language translation, has a positive effect on vocabulary growth for language learners (Oxford & Crookall, 1990; Chun & Plus, 1996a; Kost, Foss & Lenzini, 1999). The explanation for this effect is that lexical terms coded with visual as well as verbal modes will be memorised and retrieved from the memory better than lexical terms coded with only one verbal mode (Chun & Plus, 1996a). There are also suggestions that pictures are easier to perceive than a native language translation, therefore, the use of pictures can facilitate accurate memory predictions (Carpenter & Olson, 2012) and images of familiar objects can facilitate the learning of language (Deno, 1968).

Vocabulary presentation in the glossary includes the audio of word pronunciation and visual aids such as pictures of objects to cater for different learning preferences. The fact that the sound of the word is immediately presented with the new word offers another benefit (verbal mode) to memorise it. In the design of this activity, we have followed and incorporated proven learning strategies to engage students when learning a language. The activity engages students by providing them with control over what they wish to learn. In this case, it is the students who populate the glossary with new items. If this is organised as a class activity, new words are quickly added to the glossary, and are available for practice to all students. It has been shown that when the learner has the control of the instructional material the learner reports a greater positive attitude (Morrison, Ross, and Baldwin, 1992), an increased motivation and greater learning (Cordova and Lepper, 1996). This activity may evoke a sense of control and direction over the activity. The activity was designed to randomly select new words from the glossary and mix them with the old ones, however, students can choose if they wish to practise new words, or revise the old ones first and progress at a later stage.

This arrangement can save valuable time for the teacher as students create their own practice material while collaborating and peer-reviewing each other's entries. This approach gives students many opportunities to practice using new vocabulary, whilst requiring minimal input from teaching staff, apart from organisational coordination. Teachers can limit their involvement to merely proofreading and checking their students' input in the glossary if they wish to do so. Further, this activity will indicate to the teacher what is important to the learner. Moreover, it is very likely that the process of engaging students in populating the glossary with new words in itself will help students memorize the new words better. With this activity, we shift to a more dynamic and user-driven process that characterizes a game-like setting, rather than a single-trial activity (such as completing a worksheet).

Stanley (2007) completed research with regards to issues of implementing the Moodle glossary module in class. He listed the following issues. First of all, it was stated that it was crucial to explain to students how the glossary works and how to use it. A short manual including screenshots or a short instructional video can help. Second, students did not have a clear understanding of what was expected from them. Students did not realize that glossary entries were to be done on a regular basis, for instance, a few entries a week, so the whole group could benefit from the definitions given by fellow students. However, most students left it until the end of the semester to make their glossary entries. Major reason for this behavior was that students did not know where to begin and which words to define as the lecturer kept the task very open. Clearer instructions have to be conveyed to students in the use of glossary to assure benefits to all students and show value of the activity.

A few other problems can be expected when implementing the online activity linked to the glossary in teaching. If wished to be used in a day-to-day classroom environment, students must be provided with computers or laptops and Internet access. A major issue is how to make students see the value of this activity if they would use it. In this case, all students of the unit have to be encouraged to participate in populating the glossary from the beginning on.

Discussion and conclusions

These new online activities were designed to bring together various multimedia elements essential for vocabulary learning, such as images, sound and text, and to help students memorise meanings, pronunciation and grammatical properties of foreign words. We expect that these activities will enhance learning outcomes and improve the current practice resources. This tool aims to empower students and provide them with a tool that would help two-fold: give them an active role in learning through the student-generated glossary.

This paper explores three attributes of cognitive learning theory: Active learning and construction of knowledge, cooperation and teamwork in learning, and learning via problem solving. This activity encourages students to actively learn and construct knowledge by providing them with a platform, the glossary module in Moodle, which allows students to construct their knowledge by manipulating and structuring information. Since the activity relies on students entering new words that they have acquired, cooperation and teamwork in learning is also present. Individual students will be exposed to words that their colleagues view as important and can provide social support to each other. The online-activity offers a challenging problem-solving situation by asking students to pair a word with the correct counterpart, be it an image, a definition or the translated word. Therefore, using this activity as a whole may have a positive impact on the learning process of students.

Collaborative learning embodies all of the attributes above and the benefits of this approach are well researched. While they were initially developed for the Russian language, they are intended to be adapted to virtually every language taught at Macquarie University. We endeavor to establish the Russian unit as a leading subject in this climate of change by responding to its students needs and by introducing new methods of delivery. Apart from developing this new technology, research will be conducted to investigate the effectiveness of this online activity.

Acknowledgements

The project described in this study was supported by Teaching Delivery Grant 2012 from Macquarie University, Australia.

The road ahead: eBooks, eTextbooks and publishers' electronic resources

Romana Martin
Curtin Business School
Curtin University

eBooks have now become commonplace in the community and are used on a range of mobile devices such as eBook readers and tablet computers. In recent years, eTextbooks accessible on a range of mobile devices have provided an alternative to heavy and expensive print-based resources. Although some institutions have decided that eTextbooks and related resources are the preferred option for their students, research does not yet indicate that students actually favor eTextbooks. There is also little evidence to support whether the additional features offered in electronic resources increase engagement or improve learning outcomes. The author describes how a review of the literature revealed current issues related to eTextbooks and their accompanying resources. This preliminary exploration will guide research to investigate whether eTextbooks and complementary resources produced by publishing companies can lead to improved learning outcomes and student engagement in a business school context.

Keywords: engagement, learning outcomes, eBooks, eTextbooks, mobile devices, iPad.

Introduction

In 2011, The Horizon Report (Johnson, Smith, Willis, Levine & Haywood, 2011) stated that electronic books were moving closer to mainstream adoption by educational institutions with features such as immersive experiences and facilities for note-taking, research activities and social interaction. The 2012 edition of The Horizon Report (Johnson, Adams, & Cummins, 2012) highlighted the emergence of tablet computers as a significant distribution element for electronic books in higher education. Furthermore, the literature shows that a number of institutions are promoting a shift to eTextbooks due to the possible benefits of reduced costs and higher portability (Cross, 2010; Murray & Perez, 2011). In the wider community, eBooks and 'e-reading' are growing in popularity (Rainie, Zickuhr, Purcell, Madden, & Brenner, 2012) mainly due to e-Book portability and ease of access. However, it is still uncertain whether the uptake of eTextbooks will be as dramatic as that of fiction and non-fiction eBooks, as the landscape of eTextbooks and educational resources has become increasingly complex due to the myriad of choices.

The availability of eTextbooks with embedded features such as interactive images, animations, quizzes and simulations is relatively new. The characteristics of this new generation of textbooks offer opportunities that were not available in the past. Some studies have shown that, compared with traditional media, eBooks and eTextbooks provide additional features such as: portability, text searching abilities, quizzes, web links, interactive learning activities, bookmarking, and annotations (Rickman,Von Holzen, Klute & Tobin, 2009; Wilson, 2003). Social networking and collaborative learning through sharing annotations are aspects of eBook environments that may also have an impact on learning (Richardson, Smith, Lenarcic, McCrohan, & O'Hare, 2010). However, current research is not conclusive about the benefits of adopting eTextbooks and it has yet to be established how eTextbooks and other electronic resources could be used effectively by both students and lecturers to enhance the learning and teaching process (Murray & Perez, 2011).

To date, studies investigating student preferences in textbook formats have, in some instances, shown that students welcome eTextbooks over hard copy texts (Porter, 2010; Ugaz & Resnick, 2008). Whereas others have found that students still favored hard copy textbooks to eBooks, or a combination of the two, which are available from some publishers (O'Hare & Smith, 2012; Woody, Daniel & Baker, 2010). Although eTextbooks are usually less expensive than their hard copy equivalents, they are often provided via a rental arrangement for 6-12 months, and in some cases are not transferrable from one device to another (Nicholas & Lewis, 2010). Despite the wide availability of eBooks, some students prefer to have hard copy textbooks to keep for future reference, or for their resale value (Murray & Perez, 2011).

In 2008, Lam, Lam, Lam and McNaught explored students' perceptions of usability and usefulness of eBooks in learning and found that advantages such as portability were outweighed by a range of technological difficulties experienced by their students. They therefore concluded that eBooks were still in an early developmental phase. A later study by Woody et al. (2010) established that the necessary resources (e.g. computers and support) must be provided for eTextbooks to be successfully adopted. Table 1 lists some of the advantages and disadvantages of eTextbooks based on the literature (Nicholas & Lewis, 2010; Nicholas, Rowlands & Jamali, 2010; Rickman, Von Holzen, Klute & Tobin, 2009; Wilson, 2003).

Table 1: eTextbooks advantages and disadvantages

Advantages	Disadvantages
Portability	Platform limitations
Text searching ability	Poor navigation
Lower price of eTextbooks	Expiry of access (some 3-6 months) Non-transferrable access
Accessibility for visually impaired	Some resources are not accessible for visually impaired
Available online and on mobile devices	Unavailability of some texts as eBooks
Bookmarking	Device specific and non-transferrable bookmarks
Annotations	Annotation and copy and paste limitations
Can print a copy	Printing may be limited or prohibited

The variability in platforms (other than PDF) and single platform availability of some products can also limit their usability and uptake (Richardson & Mahmood, 2012). Some of the commonly used formats and platforms for eTexbooks and resources are summarised in Table 2.

Table 2: eBook and eTextbook Platforms

eBook Readers	Platform
Amazon Kindle	Both PC and Mac, Apple iOS (iPad, iPhone), Android devices (tablets, phones)
Apple iBooks	Apple iOS only (iPad, iPhone, iPod touch)
Sony Reader	Android devices (tablets, phones), Sony devices (tablets, readers)
Kobo	Both PC and Mac, Apple iOS (iPad, iPhone), Android devices (tablets, phones)
Web-based eTextbook Environments	**Platform**
VitalSource	Both PC and Mac, Apple iOS (iPad, iPhone, iPod Touch), Android devices (tablets, phones), Blackboard Building block
Course Mate (Cengage)	Both PC and Mac,-not all mobile devices
WileyPLUS	Both PC and Mac, not all mobile devices, Blackboard Building block

The move to electronic formats has enhanced resource flexibility, particularly due to the ability to mix and match chapters from various textbooks an option provided by some publishing companies (e.g. McGraw-Hill, Wiley) and the capabilities to develop custom eBooks (e.g. McGraw-Hill Create http://create.mcgraw-hill.com/wordpress-mu/australia-newzealand/). The DIY approach to authoring eBooks can be as simple as developing texts in PDF format, or alternatively, using authoring applications and apps e.g. iBooks Author for iPad iBooks (.ibooks format) or Calibre, Adobe Indesign 5.5, Creative Book Builder (ePub format). Apple's iBooks (Textbook) format was released in 2012, but at present produces eTextbooks that are only compatible with Apple devices. If appropriate resources are available, eBooks can be developed in a range of formats and can include animations, interactive quizzes, embedded media such as video and audio recordings, and provide facilities for rotation and scaling of items.

Equity and accessibility are two major concerns when introducing a new range of resources and eBooks can be more accessible solutions for students with visual disabilities. For example, Macquarie University adopted an eBook publishing model (ePub format) to facilitate increased accessibility to learning resources (Lovell-Simons and Kerr, 2011). When designed within the web-accessibility standards, the resources can be read by text reader software (e.g. Jaws) or VoiceOver on the iPad, and also allow for on screen enlargement for visually impaired students. On the other hand, accessibility and equity issues can also arise where resources are platform or device specific. For example, some resources will work only on an iPad (e.g. iBooks Author); while others have components that will not work on an iPad as they include Flash-based components or other interactive content.

Institutional Perspective

From an institutional perspective and beyond the preferences of individual students, eBooks and eTextbooks may be able to provide cost effective solutions for future learners. Some universities and libraries, such as the Northwest Missouri State University (Rickman et al., 2009), are developing institutional strategies for making eBooks and eTextbooks available to their university community. In some cases, the resources are being provided on mobile devices. For example, the Faculty of Science at the University of Adelaide piloted iPads and electronic texts or resources for all first-year undergraduate science students during 2011/2012 (Cross, 2010; University of Adelaide, 2010; 2011). In this instance, each student received a free Apple iPad to use with online curriculum and custom content. The aim of the project was to phase out printed textbooks in favor of offering a range of rich media resources that were ideally open-source or authored by teaching staff.

Additional e-Resources

In the not so distant past, the norm was a hardcopy textbook with some lecturer resources in the form of slides and answers to textbook questions. On occasion the textbook questions were made available electronically online. The newer generations of textbooks are accompanied by a wide range of resources which may include:

- an interactive eBook with embedded media and interactivity;
- an eBook embedded in an interactive learning environment (e.g. VitalSource, Cengage CourseMate);
- interactive study guides (e.g. Wiley iStudy);
- a companion site for instructors with slides, questions and answers, video case-studies and other media; and
- simulations and virtual environments.

Furthermore, some tools can be embedded or accessed via a learning management system (LMS) (e.g. Blackboard, Moodle) where quizzes can be linked directly to the grade book/grade centre and therefore provide resources that can be also used for revision or assessment purposes and to monitor students' progress.

Although a welcome addition for many, the rich set of resources available with most textbooks/eTextbooks, increases the complexity of decision-making for teaching staff. Not only do they need to decide on what they will use (textbook/eTextbook, slides, videos, quizzes), but they must also consider the cost implications (e.g. student buys, library buys), licensing limitations (e.g. 6 month expiry dates, inability to transfer from one device to another), access via an LMS (e.g. which LMSs are compatible), technological limitations (e.g. runs only on iPads versus includes Flash and will not run on iPads), and equity issues (e.g. students have access or devices that support the resources). Given these issues, the role of the educator is likely to be critical to the effective use of eTextbooks and the related electronic resources. For instance, Wong, Liong, Lin, Lower and Lam (2011) suggest that a key to successful use of eTextbooks is for lecturers to proactively make use of eTextbooks in facilitating teaching and learning. Similarly, Sun, Flores and Tanguma, (2012) established that successful uptake of eTextbooks would be facilitated by lecturers actively engaging students in using eTextbooks. Nevertheless, Nicholas and Lewis (2010) found that eTextbook uptake was not promoted by lecturers due concerns about technical issues, equity issues with access to e-readers or computers, battery limitations and students' reluctance to read on screen.

One of the first steps in integrating electronic resources and texts into learning is for lecturers to make some decisions about how the resources will be used in their unit, and to establish whether they are likely to add value for their students. There are a number of ways in which electronic resources can be utilised, as listed in Table 3:

Table 3: Approaches to using Publisher Resources

Approach	Description
Substitute for own resources	Textbook/eTextbook, publishers slides, exercises as the main resources for the unit – 'a textbook unit'
Add-on	Resources are available, promoted to students, but not integrated
Integrated/embedded	Textbook related resources are embedded within the curriculum as required
Selective use	Selected resources from multiple sources are used to illustrate concepts
Extension	Resources are used to provide additional resources for students to explore to enrich their learning experience
Assessment	Assessment tools designed by publishers (e.g. Aplia, Perdisco) are used
Social media or tools in eTextbook environment	Annotation and bookmark sharing are encouraged

In practice, there is currently little evidence about what is sustainable and good practice in using textbooks, eTextbooks, and the range of complementary resources. How should such resources be used effectively? How can the range of resources be used to support student engagement and improve learning outcomes? The future of such resources will be dependent on outcomes and input from both educators and learners.

Research directions

The complexity of the eTextbook and resource landscape has prompted the need for exploration of both the requirements and possibilities available for the Curtin Business School (CBS) and to identify whether existing resources provided by publishers of textbooks may be utilised to increase students' engagement and lead to better learning outcomes. A preliminary review of 276 publications (textbooks, eBooks and related resources) available via the university bookshop for the CBS students in Semester 1 2012, showed that approximately 19% of all the publications included an eBook version and/or a range of online resources. A review of all available Semester 1, 2012 CBS Unit Outlines (documents that provide information about required resources for each unit of study) found that only 4% of the publications with eBooks and online resources were actually referred to or promoted to students in their unit materials. Nonetheless, where such resources were described in the Unit Outlines, the electronic versions of the textbook or other publisher resources were considered to be integral to the unit.

As this is an area of rapid change and development, the availability and use of eTextbooks and related resources are likely to continue to evolve, and resources will become increasingly available for multiple platforms. The current status of eTextbook and electronic resources use at CBS has prompted a research project to explore the effective use of electronic resources in learning and teaching to identify examples of good practice. At present, there is limited current research on how eTextbooks and related resources can be effectively integrated into units, whether and how they are used by students, and whether the use of such resources results in benefits to learning or increased student engagement. Some of the issues to be explored will be the range of resources available with new editions of textbooks currently in use, hardware or software limitations, licensing and cost implications, ways in which resources could be used to add value or increase engagement, and usability and equity implications.

Designing and recording machinima to illustrate professional practice scenarios

Yvonne Masters
School of Education, Faculty of the Professions
University of New England

Barney Dalgarno
School of Education and RIPPLE Research Institute
Charles Sturt University

Sue Gregory
School of Education/ DEHub, Faculty of the Professions
University of New England

Immersive virtual worlds, such as *Second Life*, have attracted widespread interest in recent years as platforms for online role-plays of professional practice scenarios. An alternative application of virtual worlds is the video recording of in-world role-play activities, 'machinima', for later use as stimuli for class discussions or individual reflective activities. The scripting and recording of machinima to illustrate particular practice scenarios is seen as an alternative to recording video in authentic practice contexts, potentially addressing some of the inherent ethical and logistic issues. This paper describes the process used to design, record and produce machinima illustrating a series of classic classroom teaching practice scenarios as part of the Office for Learning and Teaching VirtualPREX project.

Keywords: virtual worlds, *Second Life*, role-play, machinima, professional practice, scenario based learning

Introduction

VirtualPREX (virtual professional experience), a project funded by the Office for Learning and Teaching, is designed to explore the use of a virtual world classroom for practice teaching. A consortium of universities is working to develop role-play scenarios that will assist pre-service teachers in their preparation for professional experience (practicum) placements, as well as exploring innovative ways in which these scenarios can be used for assessment tasks.

The initial development of the scenario based learning and the results of the first phase of this study have been published previously (Gregory et al., 2011; Masters, Gregory, Dalgarno, Reiners, & Knox, accepted forthcoming). In this paper we examine the development of exemplar machinima that can be used as either the basis of assessment tasks or as an example to guide students in developing their own machinima.

The paper is structured to firstly provide a discussion of machinima literature: the ways in which machinima have been used in other projects and how this has informed the development of machinima by the authors. An outline is then provided of how the exemplar scenarios were planned, followed by a description of the creation of the machinima and the technical issues that needed to be addressed. In the conclusion of the paper we discuss the value of machinima to this project and also to other fields of endeavour, thus helping to create a sustainable learning future.

Literature Review

Professional experience is well-documented as a problematic aspect of teacher education (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2009; Swabey, Castleton, & Penney, 2010). One particular concern is the shortfall in placement availability for the number of pre-service teachers in training and, more particularly, quality placements (Abbott-Chapman, 2011; Barbousas & Nicholson, 2009; O'Keeffe, 2011). VirtualPREX, by providing opportunity for teaching simulation, seeks to redress these issues. The use of machinima, for assessment and reflection, is one component of VirtualPREX. In the use of machinima, VirtualPREX overcomes the requirement for a live classroom, demonstrates teaching in a risk-free environment and also alleviates the privacy and ethical issues of filming real children.

Lowood (2011, p. 4) defines machinima as “the making of animated movies in real time through the use of digital game technology and assets”. While this form of animation was originally related to games (Kirschner, 2011), Fosk argues that machinima have advanced beyond game related animation and have now “made their way into higher education courses”, expanding “into genres that include drama, comedy, documentary, educational material, advertising, art, and political activism” (2011, pp. 26-27). It is in the genre of educational material that machinima have been incorporated into the VirtualPREX project.

Machinima have been used in other educational projects for a variety of purposes (Alden, 2008; Butler, 2010; Dreher & Dreher, 2009; Grace, 2009). Alden (2010) briefly outlines how machinima have been used to assist in health practices while Grace (2009) outlines the use of machinima for army training. Dreher and Dreher (2009, p. 5) used machinima within an Information Systems course where students developed machinima, using *Second Life (SL)*, to present a business case and report that “through the use of the Machinima screen capturing technique, students document in detail all essential aspects of their projects, thus providing a critically rich, reflective learning experience that is reusable”. The capacity for reflection and also the possibility of re-use of machinima are elements that are important in VirtualPREX. Pre-service teachers can use machinima to reflect on a range of aspects of teaching and can re-use the machinima for different purposes.

Butler (2010, p. 88) also reports the advantageous use of machinima, in this instance in legal education. He argues that too often traditional teaching “ignores the interdependent relationship of situation and cognition" and that there is a need for more contextual experiences. The work that Butler reports, where machinima were used to “depict real-world-type ethical dilemmas” (p. 91), is similar to the approach taken in VirtualPREX. The VirtualPREX researchers concur with Butler’s (2010, p. 96) comment that “the use of machinima means that, instead of considering such complex questions on the basis of disembodied names and broadly described locations in a text-based problem, they may be addressed in a more realistic milieu”. Muldoon, et al. (2008) used machinima to teach accounting concepts in an authentic setting through a story development and storytelling approach. The machinima developed for VirtualPREX reflect a similar storytelling quality.

Drawing on the ways in which machinima had previously been used to enhance education and training, machinima of the role-plays conducted by pre-service teachers as part of VirtualPREX were developed at an earlier stage of the project (see http://www.virtualprex.com/machinima.html for examples). The development of exemplar machinima was the next progression in machinima use. These exemplars have the capacity to support structured critical reflection activities, which could form the basis of assessment tasks.

Planning the scenarios

In order to prepare for the recording of exemplar machinima, two of the VirtualPREX research team undertook the task of planning the scenarios. These team members (hereafter referred to as designers) decided what the focus of the scenarios should be and how many scenarios might be recorded on the day designated for this aspect of the project and designed a planning template to capture all of the detail needed by those taking part in the role-play to follow. To complete this task, the designers, who were geographically distant, held weekly teleconferences, beginning four weeks before the recording day, and compiled email reports of the discussions allowing other team members to comment on key decisions.

The original term used to describe the machinima was ‘best practice’ scenarios. In the initial discussion, the designers moved away from this terminology believing that ‘best practice’ is a contestable notion. In teaching, views of ‘best practice’ would differ depending upon the learning theory espoused: constructivism, behaviourism, etc. The machinima to be developed, albeit enacted by experienced teachers, would have aspects in them that could be critiqued by others as not reflecting certain views of ‘best practice’. The decision was made to use the term ‘exemplar’ in preference, particularly in terms of its definition as “a typical member” (Turner, 1987): the scenarios would be developed as typical examples of how certain issues would be approached in classrooms by teachers, without claims to either ‘best practice’ or being the only approach.

After the initial discussion regarding the terminology for the machinima, the designers then discussed the template that could be used for loose scripting of the scenarios. It was believed that creating broad outlines for the scenarios was a more productive method than writing full scripts. Scripted machinima would not have allowed for spontaneity from those in the role-play and could have detracted from the natural teaching method of the person playing the part of the teacher in the scenario. In this respect, the VirtualPREX team differed from the previously reported project by Butler (2010) where scripts were written and followed closely.

One of the first tasks of the designers was to decide the issues to be explored through the machinima. It was decided that one would look at aspects of classroom management, as management of pupil behaviour had been a key focus of the earlier role-plays. It was also decided that another machinima should be developed with a focus on the basic teaching skills of introducing and concluding a lesson. To check that the approach taken was accurate, various behaviour management textbooks were consulted, and the identified scenarios were discussed with experienced teacher educators.

A template was designed, with the belief that this could be used for any scenario and could be provided as a guideline for anyone who wished to develop their own machinima. The template included the following sections: the title and overview of the scenario; the lesson content and main teaching strategies demonstrated; the actors, their roles and their avatar names; the additional avatar controllers and production staff roles; a description of the virtual environment, layout and initial positioning of the avatars; and a table containing the series of events, the timing of each and the camera positions. This template, after further refinement, along with guidelines for producing machinima, will be available from the VirtualPREX website at the conclusion of the project. The VirtualPREX exemplar role-play scenario scripts can be found at http://virtualprex.com/exemplarscenarios.html.

Acting out the scenarios

The recording of the machinima took place in a computer laboratory (lab) in one of the host institutions' campus. It took the best part of a day to record four machinima of between 3 and 5 minutes duration each. Six people participated in this, with one person managing the video and audio recording, including camera control, a second person controlling all of the non-speaking characters, and the remaining four people acting particular roles. The participants were all members of the research project team or academic staff members. None of the participants had any formal acting training. The designer of each scenario took on the role of director for the recording of that particular scenario, as well as acting the teacher in the scenario. The process of recording each scenario began with a discussion about the purpose of the scenario and the sequence of events and as part of this discussion role allocations were agreed on. Rather than rehearsing before commencing recording, we began recording at the commencement of our first attempt to act out each scenario. Our feeling was that our improvised actions and lines would sound more realistic than rehearsed performances. Nevertheless each scenario took a number of takes (the minimum was three takes and the maximum was four).

At the conclusion we saved all of the audio and video files onto a removable hard drive for editing. This turned out to be challenging due to some technical complexities with the audio recording software (see further discussion below) as well as different ways in which the audio tool was used by participants on the different computers in the lab. In retrospect, it would have been valuable to have a larger team and have one person take on a dedicated director role and another person take on the role of technical producer. The team had allocated the director role to the author of the scenario that was being role-played because they were most familiar with the scenario. However, they were also the main actor for the role-plays. It would have been more appropriate to have the main actor allocated to another member of the team to enable the director to coordinate procedures better. There was a dedicated technical producer who oversaw the machinima production, quality assurance of video, video angle and audio. However, because they were also responsible for controlling the five cameras (each attached to an unassociated hidden avatar controlled through separate computers), the technical producer was unable to also ensure that the audio software was recorded by the actors correctly (there were some takes where the audio was not recorded correctly on the particular actor's computer, but the quality of the audio captured by nearby computers was found to be sufficient).

Student avatars were provided with a variety of *SL* scripts to enable the actors to animate their avatar during the role-plays. These included pre-installed scripts from the software and also animations for sitting, reading and writing. The school student avatars were animated to respond to requests from the teacher to ensure that the machinima recordings appeared authentic.

Technical process

The technical producer set up five computers to record the machinima to ensure various camera positions and angles could be used in the final editing process. As previously mentioned, the role-plays were recorded in a computer lab, to ensure all actors used the same hardware and software platform. The original plan was for dialog to occur using *SL* audio, with actors wearing headsets to avoid audio feedback. Unfortunately, the audio was not working in *SL* due to network restrictions. To address this issue, we decided to speak out loud and record real talking. This turned out to be an excellent way of creating the audio as it was clear and crisp and ensured good quality. There was still one problem that was not foreseen. As the audio was not working in *SL*, the avatar's mouths were not lip-synced: that is, the avatar's lips did not move when speaking. This problem was overcome during production by re-recording the close ups with the avatar's lips moving when speaking. Fortunately, this was not required on many occasions.

Finally, the machinima was created using video editing. Overall, creating machinima takes several hours for a five minute script. It is much faster if high quality video images and multiple camera angles are not required. However, for the VirtualPREX machinima, this level of quality was essential.

Conclusion

This paper has reported on the process used to create a series of machinima illustrating particular classroom teaching scenarios for use by pre-service teachers as part of an in-class reflective discussions or alternatively as part of assessment tasks. We have described the process we used to design, record and produce the final machinima. Some of the key recommendations for others emerging from the process are as follows: using a loose plan for the scenarios rather than tight scripts does work, but probably requires additional takes to get right; ensure that you have sufficient people present when the machinima are recorded, including dedicated people to play each role, to operate the virtual cameras, to oversee the technical process and direct proceedings; and make sure that you set aside a longer period than you think you will need so that if you do need additional takes, or if technical problems occur, you do not need to reassemble the whole team at a later date.

As with the projects referred to in the literature review, these machinima demonstrate the capacity for this genre to be used across a range of disciplines for skill practice and also for critical reflection. They also pave the way for innovative assessment tasks. Given the reported difficulties with professional experience placements referred to in the literature review, machinima provide a sustainable approach to support future teacher training preparation. This approach could make a lasting contribution to the way professional experience is delivered into the future.

Promoting asynchronous interactivity of recorded lectures in blended learning environments

Bernadette K McCabe
Faculty of Sciences
University of Southern Queensland

Carola Hobohm
Faculty of Sciences
University of Southern Queensland

Recorded lectures have become one of the most popular methods of delivery in a blended learning environment (Greenberg & Nilssen, 2009). While there are many advantages to using recorded lectures they are limited in their ability to capture the interactive atmosphere experienced by students in the face-to-face environment. This paper examines how the use of audience response systems (ARS) and digital inking, when incorporated into live lecture recordings, can be used to facilitate asynchronous interaction of recorded lectures in bioscience lectures for nursing students. Key findings show that the three most valuable improvements that ARS and digital ink made to face-to-face lectures and recorded lectures relate to the ability to see other students' responses, immediate feedback and reinforcing material covered in class. Students who used recorded lectures more frequently particularly valued the ability to pause recorded lectures to consider the questions and then view collective results with immediate feedback. Moreover, students who viewed recorded lectures more frequently performed equally well with those students who did not.

Keywords: Audience response systems, clickers, active learning, digital inking, nursing bioscience

Introduction

A little over a decade ago Collis and Moonen (2001) posited that blended learning is a hybrid of traditional face-to-face and online learning, where the online component becomes a natural extension of traditional classroom learning. Now, blended learning has become an expectation for higher education students. A well designed blended learning approach of delivery is able to enhance the face-to-face interaction between teachers and students with online opportunities in the form of flexible, self-directed activities (Garrison & Kanuka, 2004) and is perceived to have many advantages for the learner, including anytime, anywhere access, self-paced learning, enquiry led learning and collaborative learning (Ruiz, Mintzer & Leipzip, 2006). There are many blended learning models which combine on-line material and traditional face-to-face teaching. They commonly use a central learning management system (LMS) as a platform to provide content such as online video, quizzes and other activities. The provision of electronic lecture recordings within the LMS has become an effective tool in the flexible delivery of lecture material (Woo, Gosper, McNeill, Preston, Green, & Phillips, 2008). Wieling and Hofman (2010) emphasize that offering recordings of face-to-face lectures is an easy extension of a traditional course and is of practical importance, because it enables students who are absent from the regular face-to-face lectures to be able to improve their course grade by viewing the lectures online.

It has been documented that the success of blended learning can, in part, be attributed to the interactive capabilities of online communication technologies (Swan, 2001). Literature in the field of lecture capture identifies many benefits that can be gained from recorded lectures, such as: reviewing material to complement in-class interactions; improving test scores; improving retention of class material; flexibility of schedule; making up for missed class; and the ability to clarify misunderstandings (Deal, 2007; McElroy & Blount, 2006; Nagel, 2008). One major shortcoming of recorded lectures, however, is that they are limited in their ability to capture the interactive atmosphere experienced by students in the face-to-face environment (Larkin, 2010).The potential drawbacks focus mainly on elements that students miss if they do not attend face-to-face lectures, including: lack of opportunity to ask questions and ability to obtain immediate feedback; lack of interaction with peers and/or lecturer; reduced motivation; and inability to pay attention/focus and distraction (Panther, Mosse & Wright, 2011). Chang (2007) highlights the concern that student engagement is reduced through using lecture capture hence encouraging students to become passive learners.

Whilst there is evidence that lecture capture generally supports student learning positively, there is a need to explore new ways to support active learning using recorded lectures. This perhaps represents one of the major challenges facing the effective use of lecture capture. The greatest increase in the effectiveness of lecture capture systems will come from the application of pedagogical techniques that integrate engagement and interactivity and will ultimately drive the success of this form of learning into the future.

Background

The University of Southern Queensland (USQ) supports high levels of flexibility in its programs of study by ensuring that students have equitable learning opportunities, no matter where or when they are studying. Lecture recording technology at USQ began 10 years ago and forms a central component to support flexible learning options for both on-campus and distance students.

The biological and physical sciences are an important component of USQ's Bachelor of Nursing (Pre-Registration) program. The learning and teaching of science subjects in undergraduate nursing programs can be difficult and a number of issues which contribute to this have been documented (McVicar & Clancy, 2001). An obvious disparity in science background exists amongst USQ's cohort with 60% of the enrolment comprising mature age students who either have never studied science at senior school level or may have left secondary school some 15 or 20 years ago.

Lectures have been recorded live in the course NSC1500 Biophysical Science Foundations in Nursing since 2002 to accommodate the diverse on-campus student cohort and tablet PC technology has been used on-going since 2007. Digital inking, using tablet PCs or pen-enabled screens is a technology that has been adopted increasingly within lecture recordings, both pre-recorded and live, since the ability to draw spontaneous annotation to support explanation in lectures greatly enhances communication and assists in creating close reproductions of the live lectures (Yoon & Sneddon, 2011; Ambikairajah, Epps, Sheng, Celler & Chen, 2005; Subhlok, Johnson, Subramaniam, Vilalta & Yun, 2007).

On-campus nursing students enrolled in NSC1500 can be categorised as: (1) those that usually attend lectures, but may occasionally be unable to attend; (2) those who attend face-to-face lectures about 50% of the time; and (3) those that rarely attend lectures and only attend compulsory tutorials. For many of the students who rarely attend lectures, reasons are predominantly related to travel time, work and family commitments. USQ is a regional university and many of the students are from remote areas where they may have to travel 1 to 2 hours to attend classes. Many thus rely on recorded lectures. Pilot research has revealed that 30% of students (n=97) never or only attended lectures 20% of the time and that these students use recorded lectures both as a supplement and replacement to the traditional lecture (McCabe, 2010). This provides an interesting contrast given that many studies show that students use recorded lectures to support and supplement learning rather than to replace face-to-face teaching (Brotherton & Abowd, 2004; Griffen, Mitchell & Thompson, 2009; Buchanan, Macfarlane & Ludviniak, 2010; Larkin, 2010).

Purpose of the current study

There appears to be scant information regarding how lecture capture can support active learning, particularly for those cohorts which use recorded lectures as a replacement of face-to-face lectures. Thus the challenge remains for educators to incorporate technologies which create an interactive learning experience that stimulate active learning. The relatively large percentage of NSC1500 students who rely on recorded lectures indicates that there is a necessity to enhance lectures to cater for students who are present as well as those relying solely on recorded lectures. This is perhaps especially important to support students using blended learning environments so that they can feel part of the same learning environment as campus-based students.

One strategy is to facilitate interactions during the live lecture and embed them in the subsequent lecture recording. A number of technologies have been used to promote interaction and active learning in live lectures, including audience response systems (ARS). ARS technology or 'clickers' have been used in higher education for over a decade, and a number of studies support its potential to transform classroom participation and learning, especially in science disciplines (Crossgrove & Curran, 2008; MacArthur & Jones, 2008). The technology has been used to improve student interaction, engagement and attention, increase attendance, stimulate peer and class discussion, provide feedback for both students and instructor in order to improve instruction, and improve learning performance. Kay & LeSage (2009) provide a comprehensive literature review examining the benefits and challenges of using ARS.

This study proposes to integrate ARS and digital inking within live lecture recordings as a simple approach to increase active learning whilst students view recorded lectures. The main motivating factor was firstly to provide a more interactive face-to-face learning environment for students attending live lectures and secondly, to enhance the blended learning environment by promoting student engagement and active learning using the subsequent recorded lectures. The adoption of the ARS in this study is therefore pedagogy-led (rather than technology-led) and the emphasis on teaching needs in technology-enhanced teaching is consistent with e-learning trends (for example Draper, 2009).

The aim of the study was to firstly explore how the use of ARS and digital inking in lecture recordings stimulate student active learning in asynchronous learning environments. Secondly, the study evaluated student perceptions of the combined technologies and quiz performance in relation to frequency of lecture recording use.

Methodology

Participants

The participants in this study were on-campus students who were enrolled in NSC1500 Biophysical Sciences in Nursing during the first semester of 2011. Of the 218 students enrolled in the course, 136 (62.4%) voluntarily took the survey, which was approved by the University of Southern Queensland Human Research Ethics Committee. The majority of students experienced ARS in live lectures for the first time, and none of them had used recorded lectures combined with ARS questions and digital inking. The average number of students participating in the live lecture was between 50 and 70.

Course delivery

The on campus NSC1500 course was designed as a blended learning model incorporating face-to-face, online and self-directed learning experiences over 13 weeks. Two modules of NSC1500 were included in the present study, namely chemistry and biochemistry, since these were delivered by the same instructor. The face-to-face component consisted of three 50-minute lectures and one compulsory 50-minute face-to-face tutorial each week. In addition, weekly online self-directed learning activities integrating lecture and tutorial material was provided for students to complete. A secondary teaching supplement was also provided to students in the form of a pre-study DVD which they can access both at the start of semester and throughout (McCabe, Kek and Turner, 2011). This support material was developed in response to the many nursing students who are apprehensive of their ability to understand biological and physical science concepts.

Integration of ARS and digital inking in live and recorded lectures

Audience response systems (clickers) are hand-held, pocket-size remote control-like devices that use infra-red or radio frequency signals to transmit and record audience responses to questions. The response system used in this study was TurningPoint™ software. This was used to present questions about 4 or 5 times throughout the face-to-face lecture and was tailored to hone in on specific points in the lecture. They were used for various purposes, for example: to assess students' background knowledge; to highlight known misconceptions; to review material; or to apply new knowledge to solve a problem. During the lecture sessions the software program recoded the student entries and response data was instantly aggregated and displayed. After the graphed responses were displayed the lecturer provided detailed feedback through verbal explanations and annotations on the PowerPoint slides to support the explanations.

The live lectures were captured using Camtasia Relay software (http: www.techsmith.com/camtasiarelay), which recorded the instructors voice and PowerPoint™ slides containing ARS activity and digital inking. The recorded lectures were made available soon after class in the Moodle learning management system. Figure 1 illustrates a typical slide containing an ARS question with the responses provided by on-campus students and annotations made by the lecturer using digital ink in response to the students' answers.

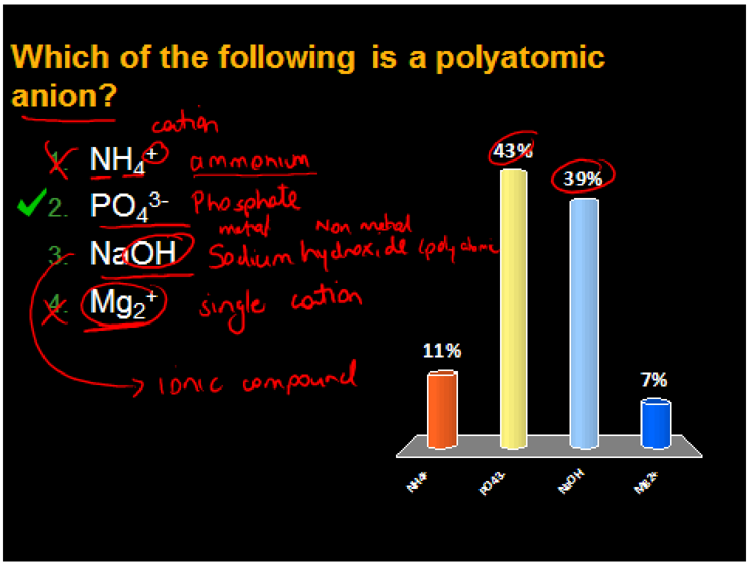

Figure 1: Screenshot example of recorded ARS question including graphed student responses and annotations to provide feedback

Student evaluation and analysis

An anonymous paper-based survey was provided during the last week of semester to the students attending tutorials. The questionnaire was designed with both quantitative and qualitative questions to evaluate the effectiveness of the combined technologies in the different learning environments, that is, live lectures, recorded lectures or a mixture of both. A concurrent triangulation research design was employed (Creswell, Plano Clark, Gutman & Hanson, 2003) where both quantitative and qualitative data were collected simultaneously, and the results of the analyses of both data sets were merged for a better understanding of the research aims. The quantitative questions related to students' perceptions of the use of the combined technologies and effects on their learning. Qualitative data was obtained through open ended questions asking students to provide their comments.

Findings

This section presents the analysis of the evaluation data. Students were firstly asked to rate their frequency of face-to-face lecture attendance and use of recorded lectures. A close correlation exists between students who view recorded lectures versus those that attend live lectures (Table 1; highlighted data). As a summary, 30% of students attend lectures while over 25% seldom or never view recorded lectures. Approximately 25% of students seldom or never attend lectures; the same percentage of students always or usually viewed recorded lectures.

Table 1: Summary of frequency of lecture attendance and recorded lecture use.

Live lecture attendance*	**Use of recorded lectures***					
	Always or usually	Most times	Sometimes	Seldom	Never	Total
Always or usually	5	5	7	16	8	41 **(30.15%)**
Most times	4	9	14	5	0	32 (23.53%)
Sometimes	6	11	8	1	1	27 (19.85%)
Seldom	12	8	2	2	0	24 **(17.65%)**
Never	8	2	1	1	0	12 **(8.82%)**
Total	35 **(25.74%)**	35 (25.74%)	32 (23.53%)	25 **(18.38%)**	9 **(6.62%)**	136

*Always or usually (>80%); most times (50-80%); Sometimes (20-50%); Seldom (<20%)

Secondly, students were asked a series of questions in order to assess their perception of the use of clickers in recorded lectures. The results of the attitudinal survey are reported in Table 2. Students indicated their responses to the first 6 survey questions shown in Table 2 using a 5-point Likert scale: (1) strongly disagree; (2) disagree;

(3) neutral; (4) agree; (5) strongly agree. The next 2 questions used a 4-point Likert scale: (1) not important; (2) neutral; (3) reasonably important; (4) most important. The 8 questions express the students' responses as % agree and % disagree, or % important and % not important, calculated from the sum of students who responded in each category. The mean and standard deviation of the students' responses are also given; indicating the larger the mean value, the more positive the students response.

The first aim of the study was to explore how the use of ARS and digital inking in lecture recordings stimulate student active learning in asynchronous learning environments. The survey data in Table 2 show that the majority of students agreed that clicker activities included in the lecture recordings enabled them to (1) revise the questions multiple times (69.9%); (2) helped them focus when replaying long lectures (64.5%); (3) helped reinforce the material covered in class (76.1%); and (4) enabled them to 'stop-think-answer' (69.9%). The most positive responses were regarding the ability to see responses of other students' answers to gauge levels of understanding (82.6%) and immediate feedback (81.9%), while incentive to play/replay all the lecture recordings and encouraged better grades were rated to a lesser extent (49.3% and 57.9% respectively).

Table 2: Student perception of use of ARS in recorded lectures

Question	Agree (%)	Disagree (%)	Mean ± SD
1. The clicker questions included in the lecture recordings enabled me to revise the questions multiple times which is important for the way I study	69.6	5.0	3.88 ± 1.05
2. Having the clicker questions included in the lecture recording has helped me keep my focus when replaying long lectures	64.5	7.9	3.83 ± 1.11
3. Having clicker questions included in the lecture recording has given me incentive to play/replay all the lecture recordings better	49.3	15.2	3.44 ± 1.09
4. Being able to go through recorded clicker activities has helped me as it reinforces the material covered in class	76.1	5.0	4.04 ± 0.94
5. Seeing responses of other students' answers helped me gauge my level of knowledge	82.6	3.6	4.01 ± 0.78
6. The clicker questions encouraged me to get better grades	57.9	14.5	3.62 ± 0.86
	Important (%)	**Not important (%)**	**Mean ± SD**
7. When viewing the lecture recording, you can stop the recording at the clicker questions, think about the answer and then play the recording to reveal and cross check the answers. How useful do you rate this capability of 'stop-think-answer' for your studies	69.6	5.8	3.00 ± 0.99
8. How important do you rate the immediate answer and feedback provided with the clicker questions?	81.9	3.6	3.24 ± 0.90

The qualitative findings also broadly support the quantitative results. Themes emerged around increasing focus and the ability to revise/reinforce lecture material. Students reported that:

> They encouraged me to actively think rather than sit passively in the lectures – very good for learning.
>
> It was a good exercise because I enjoyed being attentive - it minimized boredom and daydreaming.
>
> I really enjoyed them; it helped me focus overall on the material as a question might have been coming.
>
> Overall I found the clickers to be an AWESOME idea. Helps keep me going when listening to the lectures.
>
> Introduced throughout the lecture definitely breaks it up and ensures you are on the right track and understanding it all. Made the lecture more interesting and engaging.
>
> Even though I attended the live versions I found clicker questions good for rewatching, as I do often get sidetracked in thought.

The combined use of digital inking and clicker feedback in providing effective feedback was another theme that emerged from the qualitative comments. The ability to obtain immediate feedback from both the teacher and other students (i.e. ability to see peers' responses) proved equally important. Students reported that:

> Recorded lectures with clicker questions and interactive slides e.g. writing on slides as we go is the best way for me to learn in an online environment.
>
> I found the clicker feedback with the red pen allowed me to make connections in the work we had to learn.
>
> I found this a great help as I would pause the lecture and write the questions and answers down.
>
> I felt that I definitely enjoyed the lectures that used clickers and it was really good to see where my level of understanding was in comparison to my peers.

The second aim of the study evaluated student's perception of the combined technologies and quiz performance in relation to lecture recording use. A t-test was used to compare students' who attended lectures more than 80% of the time with those that never or seldom attended. Table 4 shows that there was only a significant difference in students' perception of the use of clickers for the stop-think-answer method (question 7). Students who never or seldom (<20%) attended lectures found this function particularly useful compared to students who preferred to attend the live lecture.

Table 3: Student perception of ARS in recorded lectures depending on lecture attendance

	Lecture Attendance				t-test (cf >80%- (20% - Never)
Question	**>80%**	**50-80%**	**20-50%**	**<20% - never**	
1.	3.68 (1.31)	4.25 (0.72)	3.67 (0.92)	3.94 (1.01)	0.328
2.	3.63 (1.16)	4.00 (0.98)	3.78 (1.01)	3.94 (1.22)	0.257
3.	3.27 (1.14)	3.56 (0.98)	3.41 (1.01)	3.56 (1.21)	0.288
4.	4.15 (0.99)	4.09 (0.78)	3.78 (0.85)	4.08 (1.08)	0.791
5.	4.05 (0.92)	4.03 (0.59)	3.81 (0.88)	4.00 (0.96)	0.821
6.	3.54 (0.87)	3.72 (0.77)	3.44 (0.80)	3.75 (0.97)	0.315

One student who attended less than 20% of the time reports that:

> Recorded lectures can cause your mind to drift – the clickers have made the lectures interesting and have helped me stay alert. I was also able to pause the lecture think about my answer, then see if I was correct or not.

Figures 2(a) and (b) show results from an online quiz given to students at the completion of the chemistry and biochemistry modules. Apart from two outliers at 8 and 18 lecture views in Figures 2a and 2b respectively, it appears that students who view lectures more frequently perform equally well, if not better, compared to those students who used them to a lesser extent if at all.

Discussion and Conclusion

Many higher education institutions support the policy that blended learning encompasses the obligation to provide equitable learning and assessment experiences between and across different cohorts. The pedagogic issue therefore is ensuring equal treatment for all students. Brandt (cited in Russo & Campbell 2004) suggests that many students expect online courses to mirror face-to-face classes in providing opportunities for interaction, idea generation and confirmation associated with constructivist learning. Such expectations were promoted through the provision of ARS and inking enhanced lecture recordings in this study. Both quantitative and qualitative findings provided support that the three most valuable improvements that clickers and digital ink made to face-to-face lectures and recorded lectures relate to: (1) the ability to see other students' responses; (2) the ability to obtain immediate feedback and (3) the ability to revise/reinforce material covered in class.

Seeing responses of other students' answers rated the highest positive student experience in this study. Maintaining a sense of community and interaction amongst students is critical to the success of online delivery (Rovai & Jordan, 2004). This is particularly important when considering the use of recorded lectures as part of the blended learning experience, especially in light of the relatively high percentage of students who rely on recorded lectures in this current study. Collaborative learning implies a more dynamic communication among learners that brings about knowledge sharing. Capturing students' responses in the recorded lecture via the use of embedded clicker questions has created a form of peer review activity not normally afforded by traditional lecture recordings by allowing students to see each other's responses. Race (2006) suggests that peer instruction/feedback can itself allow students to learn from each other's weaknesses and the ability of students to compare their knowledge against their peers is particularly important especially in regard to confidence levels. A previous study has found that strategies which increase nursing students' confidence in studying the biosciences are central to their success in these courses (McCabe, Kek and Turner, 2011). As one student comments

> Clicker question helped me think more about the material and helped me gain confidence.

The high percentage of students who positively rated that the technology enabled provision of immediate feedback facilitates active learning through the inclusion of clickers in the recorded lectures. Generally, formative feedback during the learning process helps students to correct misunderstandings, gain clarification, identify gaps in knowledge, and flaws in logic (Beatty, 2004). Feedback from students to the instructor allows on-the-spot adjustments to instruction, such as trying a different explanation, providing amplification with discussion, or using additional learning exhibits. Likewise, the feedback obtained from the clicker questions in the current study provided a dual purpose, allowing both students and teacher to benefit. The additional use of digital inking in the feedback process provided another dimension to the teaching process which can be absent from other methods of clicker instruction and lecture recording.

Recorded lectures enable students to be strategic in their use of recordings for review and repetition of key or difficult concepts. However, it is important that students are able to navigate to sections of the online lecture they felt were the most relevant to them. Davis, Connolly & Linfield (2009) found that students were actively choosing specific sections of the content to review rather than passively revisiting entire lectures. However, finding the critical concepts can be difficult for the less advanced students. It has been found that students can spend a copious amount of time listening to recorded lectures without understanding key concepts. Owston, Lupshenyuk and Wideman (2011) found that highest achieving students fast-forwarded to sections and watched them once, whereas the lower achieving watch the whole video for each class multiple times or watched the entire recording once and sections multiple times. The current study has shown that embedding clicker questions can potentially enable the viewer to identify the key learning concepts and thus aid in the revision process. This is supported by the use of the 'stop-think-answer' method which was valued more highly by those students who used recorded lectures frequently. Moreover, an analysis of viewing patterns of recorded lectures show that those students who viewed lectures more frequently performed equally well in quizzes compared to those students who accessed them less frequently. Interestingly, Le, Joordens, Chrysostomou, & Grinnell (2010) found that students who used the pause and seek features in a maths course performed more poorly than students who used lecture recordings for a concept based course in psychology. Like maths courses, the disciplines presented in the current study differ to the teaching of a concepts based course in their emphasis on the teaching of cognitive skills that are enhanced with practice. This study has shown that, recorded lecture strategies which embed activities that apply knowledge through the application of problems, such as clicker questions, has the potential to enable students to become more proficient in disciplines such as maths and science.

Bennett and Maniar (2007) questioned the value of lecture capture arguing that it could prevent some students becoming independent learners. The survey results demonstrate that independent and self-regulated learning has been encouraged through the integration of clicker questions in the recording. The approach taken in this study aids to transform traditional lecture recording into a form more suitable for blended learning environments by engaging students in a 'pseudo-synchronous' environment, thereby allowing them to feel part of the live lectures without participating synchronously or being physically present. Thus, the ability to pause recorded lectures to consider the content (such as unanswered clicker questions), continue to view collective results with immediate feedback, and repeat this process as desired, affords flexibility to students' individual patterns of engagement (De George-Walker & Keeffe, 2010). This context also implies that the pseudo-synchronous environment provides teacher, content, student and interface interactivity, thus augmenting interaction and cohesion through measures of mediated presence (Russo & Campbell, 2004). Student engagement through stop-think-answer activities are bi-directional - albeit self-determined - and thus offer students the autonomy to learn at a pace and in the manner that suited their needs (De George-Walker & Keeffe, 2010). The present study demonstrated that the heightened asynchronous interactivity afforded by the use if ARS and digital ink in recorded lectures was especially beneficial to those on campus students who choose to use recorded lectures more, and possibly "facilitated a simultaneous independent and collaborative learning experience…where learners are independent of space and time – yet together" (Garrison & Kanuka, 2004, p. 97).

In conclusion, this study has revealed that lecture recordings with embedded clicker and annotation using digital ink create a pseudo-synchronous learning environment where students manipulate the recordings to suit their learning whilst experiencing levels of social connectivity. The use of ARS and digital ink provides dual support for both the face-to-face environment and the online environment without any extra effort on the part of the instructor, and has therefore improved both efficiency and consistency of delivery. The contextual immediacy of audio-visual activity in lecture recordings has the potential to create a sense of reality for online students. The findings of this study give support to the increase active learning provided by clicker questions and annotation within recorded lectures in a blended environment. Further evaluation of the combined technologies in a fully online environment and direct comparisons with an on campus counterpart would provide interesting insights.

Acknowledgements

Three-dimensional virtual learning environments (3DVLEs), such as Second Life, have been used in education for some time. Although many writers have addressed where, how, and why 3DVLEs are applied in education, only a few articles have concentrated on the coalface of running a learning project within them. This paper looks at the experience of using Second Life to conduct a multi-discipline healthcare role-playing project with a large cohort of university students. It aims to add to the body of evidence highlighting the technical and logistical difficulties in running such a project, and attempts to offer solutions and advice on directions of problem solving. This paper will also add to best practices concerning the use of 3DVLEs in higher education.

Keywords: Second Life, 3DVLE, interdisciplinary, net generation, education, healthcare, technical issues

Introduction

Background

The use of three-dimensional virtual learning environments (3DVLEs), such as Second Life, within tertiary education is becoming more and more common (Inman, Wright, & Hartman, 2010). Educators quickly recognised the potential that early renditions of Second Life offered for hosting educational activities such as lectures (Baker, Wentz, & Woods, 2009), student building projects (Jarmon, Traphagan, Mayrath, & Trivedi, 2009), simulations (Rogers, 2008) and student interactions (DeLucia, Francese, Passero, & Tortora, 2009). While the use of Second Life for educational purposes is associated with several benefits, such as increased student engagement (Baker et al., 2009) and flexibility (Hansen, 2008), it is important to acknowledge the many challenges that may be encountered when using such technologies (Baker et al., 2009; Bhati, Mercer, Rankin, & Thomas, 2009; Dudeney & Ramsay, 2009; Warburton, 2009).

The purpose of this paper is to highlight and describe the technical and logistical problems that arose during a project where Second Life was used as a simulated role-playing tool amongst a large cohort of Health and Medical Sciences students. In doing so, this paper will add to the body of evidence on best practices for using Second Life for educational purposes. While there is no doubt that the experience of using a 3DVLE like Second Life in education would surely vary from institution to institution, or even from student group to student group, the current paper will be of assistance for educators planning on implementing a 3DVLE in a Healthcare Education framework.

Project description and objectives

The project discussed within this paper took place during Semester 2 of 2011, and included 185 students from multiple healthcare disciplines across the Schools of Health and Medical Sciences at RMIT University. The disciplines involved were Chiropractic [n = 93], Medical Imaging [n = 17], Mental Health Nursing [n = 32], and Midwifery [n = 43]. The aims of the project were to enhance student communication skills in the context of patient history-taking, and to provide opportunities for interdisciplinary learning.

Students worked in intradisciplinary groups of three (or two if necessary) and were expected to simulate a patient-practitioner interaction during a health case history, which was recorded via screen recording of the Second Life viewer. The resultant videos, referred to as machinima in virtual world terminology, were then submitted for assessment purposes. Students were given only a basic level of detail concerning the ‘patient’ and there were no scripts, actors or pro forma to follow. While the case spanned the four disciplines, as the ‘patient’ role was referred from one practitioner to another, the case histories performed within each discipline were independent of each other. Students in each discipline were expected to play each one of three roles in turn, which will henceforth be referred to as *practitioner*, *patient,* and *peer*. Students were also given interdisciplinary activities to perform in the hope that this would foster a sense of interdisciplinary awareness and understanding.

Student assessment tasks

There were multiple forms of assessment used within the Second Life module. Firstly, students completed and electronically submitted the machinima of their patient-practitioner role-play. As stated above, students were expected to assume three different roles for this activity. Each of these roles was designed to allow students to experience a slightly different perspective of the practitioner-patient interaction.

The role of practitioner is most familiar to students, as this is the role they are used to adopting throughout their disciplinary programs. Playing this role allows students to practice their patient history taking skills in a safe environment, without being exposed to real patients. The patient role allows students to use their practitioner knowledge, but they are required to reframe it in order to take the perspective of a client. Qualitative data collected from students indicated that this role was highly beneficial, as several students felt that playing the role of patient enabled them to develop a greater sense of empathy with their own patients. The peer role, on the other hand, allowed students to watch a practitioner-patient interaction with a sense of objectivity. This role gave students the opportunity to learn from the history-taking skills of their peer practitioners, and to give them feedback as to areas of strength and weakness. Students playing the peer role were also able to act as the “camera” by capturing the audio and video of the other two students while they interacted within Second Life to produce the final machinima.

The second form of assessment required students to complete a written critical self-reflection of their three role-plays as practitioner, patient and peer. This assessment allowed teaching staff to obtain a sense of what the student had gained from the role-play experience. The following quote, taken from a Chiropractic student’s self-reflection activity, clearly demonstrates how the role-play activity has been valuable to them:

> I can see some areas in which I could improve. My language definitely needs to improve. I seem a little casual at times and need to display more empathy towards the patient. I also feel I could improve the flow of my history and control the content a little more. At times I may have gotten not enough information while at others I may have let the patient go on for a little too long. It was good to see how other students of the same discipline went about the activity. By doing this I was able to get some good ideas about how to improve my own performance but I was also able to realise what I did well.

The third form of assessment was designed to promote interdisciplinary knowledge and understanding. To this end, students were expected to access and read introductory material about each of the involved disciplines within Second Life. They were then asked to write about what they had learned from this material. Students also watched the recorded role-play of a student practitioner from another discipline and completed an interdisciplinary critical reflection on that patient history.

Benefits of the project

The project described here focused on the type of interaction that 3DVLEs like Second Life do well; human interaction. Although this interaction is limited to vocal and visual exchanges between avatars in Second Life, it would be inappropriate to call it ‘simulated human interaction’, for it is only the appearance of physical presence that is simulated here. The interaction occurs fundamentally between two or more people in real-time, and the use of voice chat throughout the role-play supports this. This allowed students to feel engaged in the virtual environment when they were performing their role-plays in Second Life:

> [The] creation of an avatar to portray myself as a qualified radiographer was definitely an engaging method for developing interdisciplinary interactions and patient communications.

One of the greatest things that a 3DVLE affords well is flexibility. Online learning platforms allow students to access their learning materials at their own convenience, which makes them extremely useful for conducting collaborative learning activities with distance education students (DeLucia et al., 2009; Eschenbrenner, Nah, & Siau, 2008; Hansen, 2008). This was definitely the case in the project discussed here, as the following quote from a Medical Imaging student shows:

> The ability to connect and learn via the internet gave us much flexibility in where we undertook our learning, be it the couch at home, the local coffee shop, or the university library, we could access and utilise the online 3D simulated environment anywhere with a network connection.

Furthermore, this project was also designed to afford students flexibility in the way they completed their assessments. They were able to come and go from Second Life, and to practice and refine their role-play performance as many times as necessary until they were ready to submit their machinima for peer-review. Several students pointed out how beneficial this aspect of the project was for them, as reflected in the following comment from a Medical Imaging student:

> I would rate the ability to complete the activities at my own convenience very high. It means I can complete tasks in my own time and practice the role-play as much as I would like to.

As the final recording was performed in the presence of peers, it allowed for immediate self and peer reflection. The following Chiropractic student identified this as an area of value to them:

> All in all the Second Life exercise has been a valuable experience, via listening to ourselves [and] others conduct [a] history on the same patient has allowed [me] to identify key [mistakes] which I have made, and to see how others do the same thing and pick up on areas in which I can improve, and to give and get reflection on the task is invaluable.

The flexibility of the 3DVLE also provided opportunities for interdisciplinary interaction between students. Due to factors such as timetabling differences and being sent out on external clinical placements, opportunities for on-campus interdisciplinary interactions are rare. However, while completing the learning activities in Second Life, some students were able to interact virtually with students from other disciplines. Qualitative data showed that when these chance meetings occurred, students reported them favourably. For instance, one chiropractic student offered the following anecdote:

> Whilst roaming the streets in the Second Life location I met a girl in the mental health profession. We discussed different ways we would approach the maternity case we were given and it made me realise that although we go through psychology in class, its not quite to the extent that a mental health patient is taught. The interaction with this student made me see the benefits of referring a patient out if I thought that they had a psychological element to their history.

If the course of study is to be run across disciplines synchronously, the encouragement of such interactions within the 3DLVE could be a desirable approach.

Another benefit of this project stemmed from the role-playing activities. The activities used with this project allowed for a range of roles to be played by the learners. An ability to strongly emphasise reframing, specifically in the patient role, was also presented. In the Second Life module described here, scripts, actors, or automated responses were dispensed with in favour of students being expected to engage with the material in an educated way. This allowed them to reframe the knowledge they have acquired from the perspective of a practitioner in order to play the role of patient.

The peer role added an opportunity to objectively reflect on a performance. This is also true of one of the major components of the project; the interdisciplinary interaction. If more than one involved discipline runs their projects at the same time, and lines of communication are efficient, students from one discipline could act as a peer for students from another discipline. This would allow a unique insight into the workings of another discipline concerning the same patient. If the courses from each discipline are not running in synchronisation, role-play machinima from one discipline can serve to act as material for peer review. In the current project, the latter arrangement was the case. In the event that a discipline does not have a bank of machinima to contribute, interdisciplinary roles can still be assessed by students if the instructors of both disciplines come together to make a range of "exemplar" interactions. This would also facilitate the use of rubrics to assess student reflections. This approach would be of great benefit, not only when the project is used asynchronously, but also if a "patient" does not cover an area of interest within one of the discipline's course of study, but does for another.

Difficulties with the project

The venue

The location where students and staff are to access the 3DVLE seems to greatly influence the resultant difficulties and hurdles, sometimes in quite paradoxical ways. The use of 3DLVEs would be most appropriate where minimal (or a complete absence of) campus presence is used in the delivery of the course of study. The project described here involved a varied mix of distance educated/off-campus students, students who spent some time on campus before heading out on external placements, and students educated on-campus. This meant that allowances had to be made for the place and means by which students wished to conduct the learning tasks and related activities.

Students were encouraged to perform the assessment tasks off-campus using their own equipment. They were given a detailed set of instructions on setting up the Second Life 2 viewer, and also in gaining access to the Second Life island (a purchased area of virtual land, usually bounded by virtual water) where the tasks were to take place. The qualitative data gained from the project indicates a wide spread in the success of this. Some students had little to no problem in installing, configuring and accessing the required software for use at home. There were others however, who had great trouble in getting the required software working. For instance, one student commented:

> My computer was quite old, so downloading the software was much more difficult than it should have been.

As the above quote highlights, the reasons given by many students centred around insufficient computer specifications, though these are quite undemanding on lower (but still usable) settings of the viewer, especially for use in the confines of a virtual office environment. There was also some difficulty with accessing the island within Second Life, which some students perceived as a technical issue:

> The downside was the technical difficulties such as getting an invite by the administrator, and particularly getting into the clinic.

One of the great difficulties in managing software for a Second Life project is the huge range of variables that are at play. Such variables include the type of platform (PC/Mac/Linux), the operating system and version of said, the configuration of the system, and the firewall rules of the off-campus Internet access. Quantitative data collected from students showed that the majority used a computer "often" or "frequently", however most of the students who experienced difficulties seemed incapable of seeking a solution themselves, or using the vast online resources available concerning the use of Second Life. This would seem to indicate a culture of Technology Consumers rather than Users. In support of this, Selwyn (2009) challenges the view that the current generation are "digital-natives" or talented users of technology, and argues instead that their use is unspectacular. Perhaps one could say that such Users consume technology when it is presented in a user-friendly, or palatable, form, but find difficulty when they must use it in a way that involves a deeper level of understanding.

On-campus access to Second Life can result in more control over the aforementioned variables, but this may be incumbent with its own difficulties. One can, to a certain degree, ensure the minimum requirements to operate 3DVLE software are met, as most office computers should fall within the minimum system requirements needed for Second Life. There is the matter, however, of IT support at the host institution. Each location (computer/workstation) needed for 3DVLE access must have the required viewer installed, and be maintained and updated regularly. This last point is crucial, as when updates are released, older versions may cease working. In a small institution where one computer lab is maintained, this may be an easily managed task, however once multiple labs, differing user groups, and increasing administrative complexity are involved, this task can be a real risk to the success of the project. Linden Labs, the proprietors of Second Life, have a detailed guide for system administrators and IT security, which should aid in matters of configuration and firewall measures (Linden, 2012). In the experience of this project however, it is apparent that they may require the approval of newer rules than are already in place. This was the cause of several delays, and a degree of staff and student dissatisfaction during the project.

Along with basic firewall settings, audio settings such as default enabling of the microphone and speaker ports, and configurations such as proxy settings, are also important. The viewers used in 3DVLEs access the Internet via different streams of traffic, therefore in-world access to multimedia and the Internet may involve a proxy. Furthermore, voice chat may use a different path than the rest of the Internet traffic generated by the viewer. Once again, tight restrictions can cause problems in the function of the viewer, which can affect the completion of the assessment tasks and reduce student satisfaction. In the experiences of this project, increasing IT administrative complexity led to increasing division. Moving from one lab to another, or one campus to another, sometimes resulted in moving to an area where the configuration rules had not been changed to allow the Second Life specific traffic, which once again limited access and usability. A very clear and definite list of requirements to IT administrators will go a long way to alleviate this, but such complicated bureaucracy can be a very real and ongoing danger to such projects.

As the use of 3DVLEs would preferentially involve real-time voice chat between the participants, there is a desire to provide an on-campus environment to support it. It was notable in the feedback from our students that a general computer lab environment was not ideal for this purpose. Students reported that sharing the lab with general users made it difficult to secure a computer when they wanted to use it (groups of three were needed for the tasks in world). In situations where students were able to secure computers, they felt that environment was too noisy to converse freely using headsets or concentrate on the interaction. So too, when it was time to record the machinima for the purpose of assessment, as this Medical Imaging student points out:

> [One] problem was the limited amount of computers available to complete the assignment. [The on-campus computer lab] is very busy during uni hours and recording was difficult with the background noise. This resulted in staying back at uni till late to attempt to record the role-play.

It is likely that other users not engaged in the Second Life task would also find students conversation a distraction. This is yet another reason that it is advisable to encourage students to conduct the tasks off-campus.

Virtual space

One of the first challenges when using Second Life is making sure that there is a private area, such as an island, available in order to conduct the learning activities. If an institution does not have an island, and a grant does not allow for purchasing one (and there is no budget to support same), there are cheap alternatives available such as ReactionGrid and OpenSim. Discussion regarding which of these platforms is best is, unfortunately, outside the scope of this paper. However, a 2010 pilot project at RMIT University, in partnership with the University of South Australia, used ReactionGrid. In the project discussed within this paper, the provision of University funding meant that a Second Life island could be purchased.

Whichever platform is chosen, the project is going to need at least one Second Life architect. This person is necessary for building an environment that is suitable for use in the tasks. This may be as simple as a room with chairs, or as complex as multi-discipline polyclinic (a medical clinic housing several disciplines). The latter was employed for the project discussed here, and a follow up project conducted by the same research team in 2012 will use an updated and expanded version of this facility.

Figure 1: Polyclinic facilities designed for the 2011 project

As well as an architect(s), or perhaps as part of their role, a Second Life administrator is also needed. It is not within the scope of this paper to get bogged down in any legal or ethical responsibilities that an institution has for their students' behaviour or experiences while using a 3DVLE (Grimes, Fleischmann & Jaeger, 2010). Suffice it to say, though, that it is in the best interests of students involved in such projects that an administrator locks down access to an island, or an area of an island, to the relevant staff and students involved.
A necessary outcome of locking down an island is that the island administrator must ensure that the appropriate users are able to gain access to the restricted area. There are two ways of approaching this task; sending invitations to join an access group or manually adding usernames into an 'allowed residents' list. If using the invitations method, the administrator is required to send a personal message within Second Life to all of the relevant staff and students. One disadvantage with this method is that users must be aware that they need to look at their Second Life notifications and click 'Join' to agree to be part of the group. If they fail to go through this process, additional invitations need to be sent until this task is achieved. On the other hand, if manually adding users to a list of 'allowed residents' (Second Life user accounts), there are limitations on the number of avatars allowed to access the area. Furthermore, when using this method, it is not possible to enforce access restrictions on a 'per region' basis. Instead, restrictions apply at the estate level and this will affect all regions within this estate.

Due to the drawbacks associated with the manual addition method, students recruited in the 2011 project were given access to the polyclinic using the invitations method. Unfortunately, this process was not without difficulties, and many students reported not being able to access the required areas of the island. One of the most common factors associated with these accessibility problems was inaccurate usernames. Ideally, each student would sign up via the Second Life webpage, then supply their exact username to their lecturer. The lecturer would then pass this information on to the island administrator, who would invite the user onto the island within Second Life. However, when students did not supply their exact username to their lecturers, the island administrator had to spend time looking for them. In some cases, the administrator failed to find the user, and this was far from an ideal scenario.

Another commonly cited reason for difficulty accessing the island was trouble with invitations. On some occasions, students had been invited to access the island, yet they still claimed they could not gain access. This was sometimes merely a case of the student failing to accept the invitation. One unfortunate feature of the release version that was current to the project (2.x.xx) was that users entering in “basic” mode (the default) could not see messages including invitations. This is no longer a problem in later versions (3.x.xx) of Second Life software. Invitations do need to be accepted if they are offered, but if they are not accepted and the user logs out, the invitation will be permanently removed. Unfortunately, this causes another problem, as multiple invitations may need to be sent to users who log out before accepting their initial invitation. As a problem solving measure in the 2011 project, one of two staff members with administrator access met in-world with students who had had accessibility problems. In these instances, the staff member was able to add students to the access group manually by right clicking on their avatar, and selecting ‘invite to group’ from the context menu. As a result, the user's accessibility issues were immediately solved.

In the 2012 project, it is planned to use more strict logistics surrounding accessibility. In most cases, teaching and technical support staff will run face-to-face tutorial sessions to walk students through the following activities: signing up to Second Life, gaining entry in-world, arrival at the open access area, accepting invitations to the group, and obtaining access to the restricted areas of the island. In large groups (n = 90+), or in cases where students are enrolled in off-campus programs, a variation of the 2011 method will be used. This will require students to sign up for Second Life, then lodge their username with the appropriate teaching staff member who will then verify the student's identity and pass it on to an island administrator. Certain times shall be scheduled where an island administrator can be present in-world to assist students having difficulty and invite them in to the restricted island areas. This process will provide students with immediate access, rather than the ad hoc stopgap method used in the 2011 project. While this may entail walking them through some of the processes, it is hoped that the number of students needing such assistance will be low.

The provision of extra funding in 2012 has seen the RMIT University island gain an improved welcome and orientation area. This will help with some of the accessibility issues mentioned above, as this area will not be restricted access. Students will therefore be able to gain experience in-world while they are waiting to be permitted entry to the restricted access area. This addition was made as a small proportion of students from the 2011 cohort became lost in-world, despite being given a SLURL (Second Life URL: an address for a location in-world, used the same as one would a web address). Having this extra space should also decrease student frustration, as in one session they will be able to visit and explore Second Life in an area owned by RMIT University, even without access to the restricted area. Providing the SLURL is still a suggested measure however, as it can facilitate students' movement to the task area. It is recommended that it is made as easy as possible for students to get to a host institution's area in order to minimise unwanted contact from outside users. While this does mean that users who are not from the participating institution will have access to these unrestricted areas, it at least protects students from exposure to highly public areas.

As one may have already concluded, island access problems are almost exclusively due to user/student error. It is the belief of the authors that a clear set of instructions and rigid logistics will go a long way to managing these types of errors.

Expectation

As mentioned earlier, there were a number of students across the disciplines that reported dissatisfaction and frustration at their inability to complete various stages of the tasks. These frustrations were reflected in both the qualitative and quantitative data. It became quite evident to support staff, however, that these students were often making their first contact late in the timeline, as the following quote reveals:

> The recording process was a technical nightmare. Not having the required hardware on my PC to enable my peers to hear my voice in avatar, and my PC crashing every time I entered one of the clinics was very frustrating, this with the fact of leaving it to the 'last minute', much like many of my peers did not help my cause.

This area of failed student expectation - that they would be able to set up and configure their workstation, sign up, gain access, enter the task area and perform the task in one sitting - is grossly inappropriate. One could liken this to having a written assessment due at the close of a business day and choosing to go and buy a computer that same morning, expecting to be able to finish in time. The root of the concern then is a combination of user error, apathy and procrastination. However, some student feedback indicated the root was in the project itself:

> With the large amount of technical difficulties experienced, this limited our time in Second Life which also limited the possibility of interacting with other disciplines. The technical issues took up approximately 50% of the time during the assignment and [were] a major limiting factor.

These sources of frustration for all concerned would seem best eradicated by a strict timeline and well planned times for support, especially for off-campus students. It appears that a confounding factor in this is students' familiarity with computers at a user level. Our data revealed a clear relationship between the amount of students reporting that they have used 3DVLE/MMPORGS and the amount of students reporting that they had little problem in setting up for the project. It is not the intent of this paper to lay blame but, as mentioned earlier, it may be that our cohort consisted of many Consumers rather than Users of information technology. With approximately 80% of the participants being members of Generation Y, this would support Bennett, Maton and Kervin's (2008) stance that this generation, often referred to as the "net generation", is misconceived as being tech-savvy, high-end users.

Assessment and evidence of learning

As part of their assessment, students were required to submit a machinima of their role-play interactions. Unfortunately, the Second Life viewer has no inbuilt process for capturing video or audio, so a third-party application had to be used. This presented its own difficulties. The available software to easily capture screen content, with both audio from the host computer and audio originating from another source (referred to as capturing audio from microphone and speaker) is not cheap. Again, if running a small computer lab, this may not be an unsurmountable problem, as not all participants need to perform screen captures at the same time. However, in a large institution running a project with a high number of students, it can become very expensive to achieve this. The problem that occurred during this project was in using the free software, CamStudio. It has certain eccentricities and, while quite usable, was not user friendly. This was another source of much student dissatisfaction, as the following quote demonstrates:

> When it came to recording the role-play we also had several technical problems. First two of the people in my group couldn't even use the screen capture software on their computer, and when the third person could, it would only capture audio and not the visual. Again this wasted a lot of time fiddling around and doing the role-play multiple times.

Because not all participants needed to capture at once, (indeed only one out of a group of three need act as "camera") a site licence for a commercial product such as Camtasia, while not cheap, seems the best option and offers a cross platform solution. However, this licence would only be available for on-campus use, and so leaves the question of what the students would use off-campus. At the time of publication, Camtasia offer a free trial period of 30 days, though it may, (as is the case at RMIT University), be against the policy of the institution to require students to use trial software. Mac users who have Quicktime 10.x can record from their screens natively, but they cannot record both speaker and microphone audio. Again, there are workarounds for this but they are far from ideal. Whatever the chosen program, it should be able to output audio and video to set parameters that would suit electronic transmission and storage. Students may also be given instructions on compressing and converting their file for electronic transmission. However, this is another step in the workflow and is fraught with the same problems related to unfamiliarity.

In the project discussed in this paper, it was unfortunately the case where providing the evidence of learning (the machinima) became a distracting frustration for students (and staff). There were times where CamStudio's eccentricities were too much for some students to overcome. In desperation, some offered audio only recordings, which led to fewer technical issues than the machinima. On occasion, the problem was reported as being with Second Life's voice chat not activating. This can be an issue with Second Life itself, or run of the mill server dropouts, but was found to be less of an issue when off campus. Some students bypassed this altogether by using a mobile phone or Skype audio. Skype is only a slight compromise, mainly in that it requires yet another application to be downloaded and installed. However, in the 2010 pilot project, Skype was used due to a lack of native audio in ReactionGrid, and it was found to be quite adequate.

Once again, it cannot be stressed highly enough that, on many occasions, student frustration was compounded by the expectation that they would log on, complete the tasks, and log off. It is the intention in the 2012 project to encourage students to do "sound checks" before they intend to sit down and record their final interaction. It is hoped by overtly instructing students to test their settings early in the timeline, that by the time they come to finalise their performance any problems will be sorted out.

Dissemination

The very final part of the puzzle is dissemination. Once the student has recorded their performance how do they then share it with other students and teaching staff for the purpose of reflection and assessment? The host institution itself would best answer this, as it depends on the details of the project in question. The 2010 pilot project relied on physical media such as DVD/CD and USB devices, though it was apparent this would work only for small cohorts and those with easy campus access. The 2011 project used RMIT University's official dissemination tool, myRMIT, which is powered by Blackboard. Unfortunately, this medium has a known disadvantage as it uploads files via a HTTP interface, which slows the speed of uploading and does not give the user an indication of progression of the upload. Whichever vector is chosen for dissemination, it should be able to handle file sizes needed for the machinima, allow access across different disciplines or departments, and be secure. Another possible avenue is uploading to YouTube via private links. The resultant uploaded machinima can then be accessed only be clicking on a private link, and not through search or browsing. YouTube links can be shared easily via email, or whichever means is suitable for the project in question. However, when selecting a vector for dissemination, it is important to consider the given institution's rules of storage for student work. At RMIT University, the use of third party vectors, such as the aforementioned YouTube, is forbidden for official student work. This is an unfortunate barrier for the 2012 project, as being restricted from using the most suitable solution may again impact on student satisfaction.

The difficulties that students had with recording the machinima, which were discussed earlier, were compounded when it came to dissemination. It was crucial to the tasks, namely the interdisciplinary reflections, to be able to view machinima of other disciplines interactions. When there were delays in recording (which consequently led to delays with dissemination), many students felt severely frustrated at not being able to complete the necessary reflection tasks, as the following quote from a Chiropractic student clearly shows:

> It was required that we had to listen to a recording from another discipline as well as from our own [by] a certain due date. It was unfortunate that we were the only discipline in our group that actually uploaded anything by the due date, so we were unable to comment on someone's video from another course.

Suffice it to say that the above is, of course, a problem with the recording process and not with dissemination.

Points of interest

The project described within this paper afforded a great learning opportunity, not only for students, but also for the project team members. Throughout the implementation of this project, much was learnt about how best to conduct learning activities using a 3DVLE such as Second Life. The main purpose of this paper, therefore, is to provide advice for educators who are thinking of using an online learning platform for the purposes of learning and assessment. The main points of advice given within this paper are reiterated below:

- It is advisable to specifically instruct IT security of the project well in advance, and have staff perform tests at all stages.
- Use software vendor's instructions if the IT department will accept them.
- Encourage students to use their own resources off-campus. Where an on-campus venue is required, attempt to make it a quiet and contained space - preferably several small venues with a small number of workstations.
- Make sure you have technical support, both to build your virtual space and to administrate it, even if via a funded project.
- The land should be able to be used by several groups collaboratively or in isolation.
- Video and audio capture to produce machinima is difficult, and there is no one solution to meet all needs.
- Allow students plenty of time for set-up and testing, but instruct them to do it sooner rather than later. This leaves more time to go in-world and become familiar with it before trying to produce quality assessable evidence.
- Make sure participants have a clear and reasonable expectation of their ability to produce quality assessable evidence.
- Have a restricted area for students, but allow them to explore a custom-built area while access to the restricted area is arranged.
- Get students in-world and to the project area as quickly as possible.

Conclusion

The experience of this project has shown that, even with unfamiliarity and technical issues, students find 3DVLEs such as Second Life useful and engaging. They are of great use when conducting simulated face-to-face interactions in role-plays concerning a practitioner and a patient. They facilitate interdisciplinary interaction, above and beyond what can and does occur in real world clinical settings. 3DVLEs also allow a great opportunity for reframing of knowledge, and immersing students in content through the perspective of different roles. Despite these benefits, this paper clearly shows that the utilisation of 3DVLEs is not without difficulties. However, it is the opinion of these authors that, with careful planning and subsequent efforts with the same cohort, these issues can be lessened or avoided.

Acknowledgements

This project would not have been possible without the provision of a Learning and Teaching Investment Fund from RMIT University. The authors would also like to acknowledge the work of Joe Bird from Information Technology Services at RMIT University, who was responsible for designing and creating the Second Life facilities used within this project and acting as the island administrator.

Swinburne University of Technology

This paper explores the principles of skill acquisition and training transfer within the context of game-like digital training tools, expanding on previous research using an instrument scanning task in novice versus experienced pilots. While previous work demonstrated a game-like training tool is capable of developing high levels of performance within the game environment, initial findings suggest the likelihood of practical transfer to a real world environment is strongly dependent on the nature of the cognitive and perceptual skills developed. This paper investigates whether instrument scanning skills developed within a static training task transfer to a more dynamic video-based task. Despite strong performance within the static environment, preliminary data suggest a lesser degree of transfer when more dynamic perceptual skills are targeted. Findings are discussed broadly in terms of the principles of skill acquisition and training transfer, and how these principles may apply to game-like digital training tools.

Keywords: Training Games, Training Transfer, Skilled Performance, Instrument Scanning,

Introduction

Today's students and trainees grow up in a digital world, in many cases potentially spending as much time interacting with digital technologies and virtual worlds as they do with the real world around them (Gee 2007). Having grown up in this technology rich environment, it has been argued that today's learners may have developed an alternative skill set more tailored to learning within the digital world and this notion has led many researchers and practitioners to consider how to leverage these technologies for educational and training purposes (Gee, 2007). Much of this interest has focused on the use of virtual environments, serious gaming, and game-like digital training tools to build knowledge and skills relevant to the real world.

The variety of game-like technologies currently in use is immense and while some have undergone a variety of evaluations (e.g., Roman & Brown, 2008), others have seen very little if any. In some fields, interest in game-like training tools has resulted in such technologies rushed into service in order to meet the increasing training demands of both students and instructors alike. This has been particularly the case within some military training environments where the pressure to provide trainees with cost effective training tools continues to mount, potentially at the expense of proper training needs analysis and evaluation of training tools, training programs and training outcomes. "Right now, nobody wants to be the control group" (Robert Bowen, Chief of U.S. Army Training and Doctrine Command Capability Manager (TCM-Gaming), cited in Peck 2012; pg 2). Particularly within the military environment, it is critical to establish firstly whether these new training technologies represent effective training environments, but secondly whether the skills developed using digital training tools effectively transfer to real world operational environments and modes of practice. There is also the very real possibility that training with tools based on a games metaphor may lead trainees to develop bad habits or result in instances of negative training transfer, through the types of motivational incentives built in to game-like scenarios.

While the diversity, graphical detail, and ubiquitous nature of game-like training environments have developed considerably in recent years, the underlying principles of skill acquisition and training transfer have not. While game-like digital training tools differ significantly from more traditional training environments, it is still possible to effectively establish their training effectiveness based on the nature of the fundamental cognitive, perceptual, and psychomotor skills developed. This paper uses a relatively low-tech example of a game-like training tool (based on a tool developed by Kellman & Kaiser, 1994 and further modified by McLean, Wise & Williams, 2011) to investigate these issues and examines aspects of training transfer within a game environment.

Developing Pilot Instrument Scanning Skills - A game-like digital training tool

In 1994, Kellman and Kaiser developed what they termed a perceptual training module designed to promote more efficient information extraction, higher order pattern processing, and levels of automaticity in pilot instrument scanning skills (Kellman & Kaiser, 1994). The task required participants to view a static display of a standard-six aircraft instrument panel and identify the aircraft situation as quickly as possible (e.g., climbing, descending, turning etc). The findings demonstrated dramatic improvements in speed and accuracy after only a brief period of training (approximately 1 hour), both in novice participants and experienced civil aviation pilots. As to be expected, experienced pilots were initially much faster and more accurate than novice participants, yet by the end of the training task, novice participants' accuracy had increased dramatically (performing close to ceiling) and they were exhibiting reaction times significantly faster than those initially demonstrated by experienced pilots (Kellman & Kaiser, 1994). The interpretation of the authors was that this training task was clearly effective in developing instrument scanning skills in novices and improving skills in pilots. In principle, if such high levels of performance (equivalent to those of expert pilots) can be developed so rapidly, then these findings hold significant potential, especially considering that with the technology available today, such training tools could easily be disseminated across personal digital devices such as iPads or Smartphones, technologies that were not available, nor as ubiquitous, when the study was originally conducted.

While at first blush the findings of Kellman and Kaiser (1994) indicate that these game-like tasks have considerable potential for training, there is a missing link between the experimental findings and the realisation of such training potential in real world environments. As highlighted above, it is important to understand the nature of the skills being developed within the training task, and crucially, the likelihood of these skills to be applicable within a practical aviation context. Expert pilots demonstrate superior performance compared with novices when initially completing the task, which suggests that their expertise is at least of some relevance, yet the complex cockpit environment (and their extensive experience of this environment) has been significantly condensed in the simple representation provided by the game-like training tool. For example, novice participants may have merely developed a basic perceptual understanding of the relationship between instruments, without the necessary cognitive knowledge of each instrument's meaning or how it relates to other instruments in the panel. Conversely, participants may have developed a basic cognitive understanding of how different instruments interact, but no perceptual concept of how these instruments behave in a dynamic environment. Without understanding these differences, it is difficult to make an educated judgment as to whether the skills developed will prove to be in any way practical in a more realistic scenario.

The Current Study

The current study expands on the recent work of McLean, Wise and Williams (2011) who replicated the original Kellman and Kaiser (1994) instrument scanning training task in a sample of undergraduate psychology students. The findings from this research again revealed that non-pilot participants, most of whom had no intrinsic interest in aviation tasks, were capable of rapidly developing instrument scanning skills in this game-like environment demonstrating dramatic gains in reaction time and accuracy (McLean et al., 2011). This study furthered the findings of Kellman and Kaiser (1994) however by adding an important transfer condition to the original experimental design. While participants were initially trained using a stylized instrument panel as in the original Kellman & Kaiser study (see Figure 1, lower-left and lower-middle panels) performance was later examined on an identical task, except that the stylized instruments were replaced by a more realistic instrument images (Figure 1, lower-right panel) developed from flight simulator imagery (X-Plane Flight Simulator software). Interestingly, while participants were relatively successful in this transfer condition, reductions were still evident in both accuracy and response time compared with performance on the stylized instruments they first encountered in training. That is, despite completing an identical task in two highly similar environments, training transfer was not absolute. A plausible explanation is that, while participants had developed an adequate understanding of the cognitive association between the instruments, a significant portion of their skills was invested in the perceptual representation of the instrument panel and when this perceptual representation was manipulated, albeit only superficially, there was a significant impact on performance. The susceptibility of training transfer to superficial changes in the perceptual rendering of the instrument panel is particularly troubling in the context of the design of the static stimuli used in Kellman and Kaiser task. In order to interpret an aircraft situation from a static instrument display, the motion of some instruments (for example, the rotation of the altitude indicator during a climb) was represented symbolically by use of arrows (see Figure 1). The symbolic representation of direction of motion did not include any indication of the rate of motion or the degree of displacement generated by different instruments as a function of aircraft situation.

This paper seeks to explore the nature of the cognitive and perceptual skills developed within a game-like training task by further testing the robustness of these skills to perceptual manipulations, specifically, by examining the degree to which these skills transfer from a static environment (either stylized or realistic) to a more dynamic one involving real motion of aircraft instruments. By exploring performance on a similar task utilizing actual instrument motion rather than symbolic representations, significantly more demands are placed on the cognitive representations and perceptual skills developed within the static instrument training task. If the degree of training transfer remains strong within this dynamic setting, it suggests that the cognitive skills developed within the static training task are sufficiently tractable to be of use in more realistic environments. Conversely, if a reduction in training transfer is evident this may indicate that the development of adequate cognitive skills may be of little use, if the real-world perceptual cues remain indecipherable. Such a finding may have important implications for the way in which training tasks using digital technologies and virtual environments are developed for real-world operational tasks, not only in aviation, but also in a range of other skilled domains.

Method

Participants

Participants consisted of a convenience sample of three novice participants and three experienced pilots, with additional data collection in progress. Novices were aged between 26 and 33 and had no aviation experience. Those participants classified as experienced pilots were aged between 28 and 34 and had logged between 52 and 250 hours of flying experience. Participant performance will also be compared with the sample of 87 non-pilot Psychology undergraduates who performed a similar training task as part of the original McLean et al. (2011) study.

Materials

The experiment consisted of two separate instrument scanning tasks; a static instrument scanning (SIS) training task based on the task used by McLean et al. (2011), and an Instrument Failure Video (IFV) task.

Static Instrument Scanning (SIS) Task
The stimuli and procedure used in the SIS task comprised the same standard six instrument panel (Figure 1, top-left panel) utilised by McLean et al. (2011). These instruments consisted of the Airspeed Indicator, Attitude Indicator, Altitude Indicator, Turn Coordinator, Heading Indicator, and the Vertical Speed Indicator. Prior to commencing the experimental phase of the task, each participant was given a detailed explanation of each instrument and how to interpret them in combination. As in Kellman and Kaiser's (1994) task, in each trial the participant was presented with a panel of six instruments, with the objective to determine the aircraft 'situation' as quickly as possible – i.e., "Straight and Level", "Level Left Turn", "Level Right Turn", "Level Climb", "Level Descent", "Climbing Left Turn", "Climbing Right Turn", "Descending Left Turn", or "Descending Right Turn". An additional aircraft 'situation' was also represented where the instrument panel displays "Incongruent" information. For example, as shown in Figure 1 (lower-middle panel), five of the six instruments display a level climb, yet the altitude indicator is incongruent suggesting a descending aircraft. Participants first completed a short series of 10 practice trials before completing 3 blocks of 30 trials utilizing the stylized instrument panel (a total of 100 trials). Following these blocks, participants then completed a transfer condition block (30 trials) in which performance was evaluated on an identical task utilizing a set of stimuli generated using more realistic instrument images (Figure 1, lower-right panel). See McLean et al. (2011) for further details.

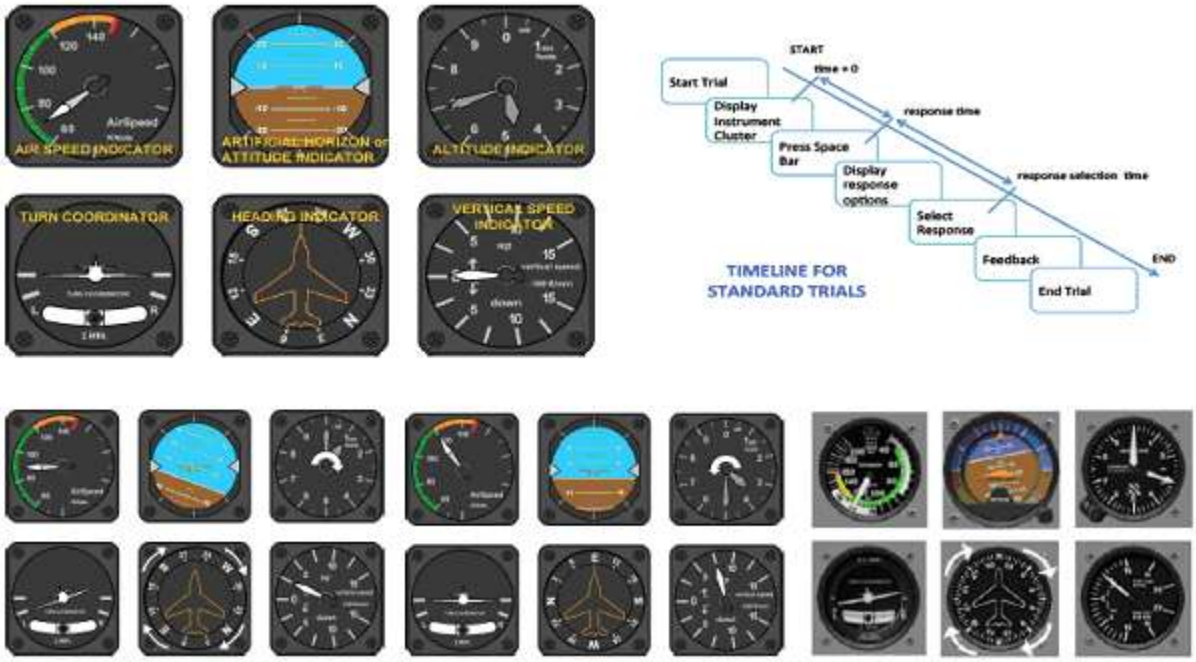

Figure 1: Experimental stimuli. Top-left panel shows the six main instruments of a Cessna cockpit as stylized static stimuli. The top-right panel shows the timeline of stimulus presentation for each trial within a standard trial block. While the top-left panel is congruent with a straight and level aircraft situation, the lower left panel is compatible with a climbing left turn. The middle lower panel conversely shows an "Incongruent" display, with most instruments compatible with a level climb, yet the altitude indicator suggests a descending situation. The rightmost lower panel shows the transfer condition using a more realistic instrument display.

Instrument Failure Video (IFV) Task

In the IFV task, participants viewed 32 short 30-second videos of flight simulation footage captured using flight simulation software (Laminar Research, X-Plane – see Figure 2 for a screenshot). Each segment would start with the aircraft flying straight and level, before executing one of the maneuvers depicted in the SIS task (e.g., "Climbing Left Turn", "Descending Right Turn" etc), and then finally returning to straight and level flight. In half of the video segments, at the 10, 15, or 20 second mark, one of the instruments would 'fail' (i.e. pause) and hence cease to be congruent with the other instruments (akin to the "Incongruent" aircraft situation in the SIS task). The participant's objective was to observe the video and determine whether any instrument had failed, and identify that instrument as quickly as possible by clicking on the instrument with the mouse.

Figure 2: Example of a screenshot from the IFV task showing the aircraft flying straight and level. In this example, the Turn Coordinator (highlighted in red) has failed indicating a left turn while the remaining instruments suggest straight and level flight.

Procedure

After receiving a series of instructional slides explaining the nature of the task and the instrument panel, participants first completed the IFV task. Following the completion of the IFV task, participants were given a further series of instructional slides before completing the SIS training task inclusive of both the stylized and realistic instrument panel (i.e. transfer condition) trial blocks. Once participants had completed the SIS training task, participants repeated the IFV task with pre and post SIS training performance evaluated across both the experienced and novice pilot participant groups.

Results & Discussion

As shown in Figure 3, initial analyses examined the accuracy and reaction time of novice versus experienced pilots on the SIS task. Consistent with the findings of Kellman and Kaiser (1994), experienced pilots had an initial advantage in accuracy and response time, but non-pilots became as fast, although not quite as accurate as pilots after only 90 minutes of training. Performance of non-pilot undergraduate psychology students from the original McLean et al. (2011) study is also shown in Figure 3 to provide context from a larger sample of participants. It should be noted that differences in performance between the novices from the current study and the undergraduate psychology students from the McLean et al. (2011) study are potentially due to differences in experimental procedure with the undergraduate psychology students completing the study via online delivery (i.e. unsupervised), while the novices in the current study participated in a supervised laboratory environment with substantially fewer trials per SIS block. Furthermore, the small sample size and fewer trials per block may account for the high level of variability in the novice and experienced pilot sample.

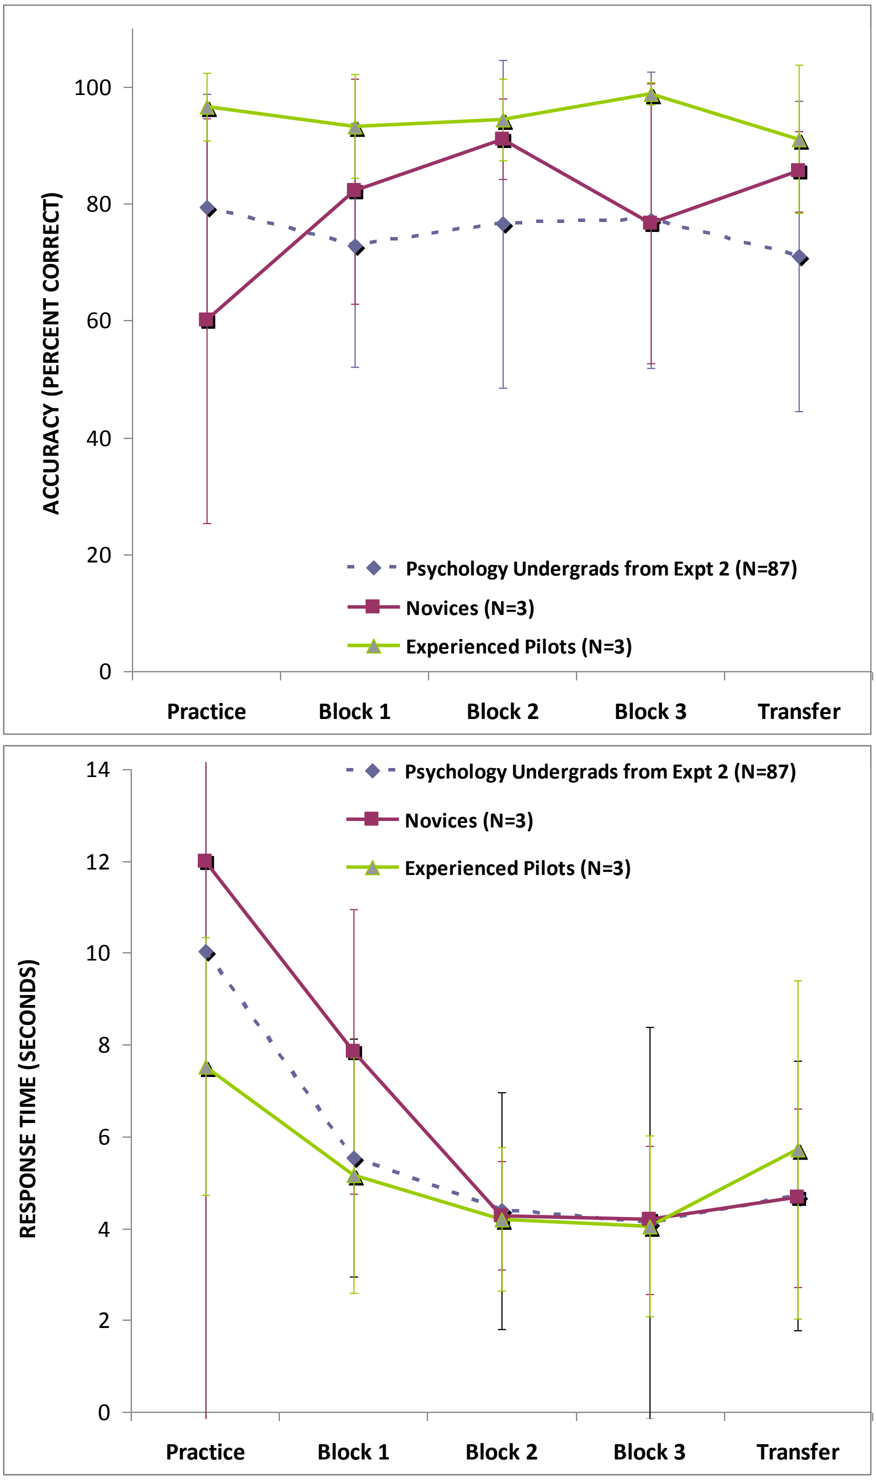

Figure 3: Accuracy and Response Time data for Pilots, Novices, and psychology undergraduate students on the static instrument scanning task (Error bars represent Standard Deviation). See text for further description.

In relation to performance on the transfer block, similar to previous findings discussed by McLean et al. (2011), there was a small reduction in accuracy on the realistic SIS transfer block for experienced pilots, although this trend did not occur for novices in the current study and did not reach significance for either sample. In terms of response time in the transfer block, while participants exhibited faster responses compared to their initial attempts at the stylized SIS task, all participants in both the novice and experienced pilot groups exhibited slower response times compared to the final training block of the stylized SIS task. As discussed above, while there was substantial training transfer between the stylized and realistic SIS conditions, transfer was certainly not absolute.

In regards to performance on the IFV task, Figure 4 highlights performance on the task both pre and post SIS training. Similar to the pattern of performance evident on the SIS training task, when first completing the IFV task the experienced pilots exhibited superior accuracy compared with novices. That experienced pilots exhibit superior performance on this IFV task prior to SIS training suggests that the task has considerable ecological validity and is tapping into significant aspects of the pilots' aviation experience. Experienced pilots proved capable of identifying the majority of instrument failures (in fact two pilots performed at close to ceiling – above 90% accuracy). Conversely, novice participants identified approximately half of the instrument failures correctly, that is, they performed at close to chance.

In regards to post SIS training performance on the IFV task, experienced pilots exhibited little gains in accuracy (83%) compared to pre SIS training performance although this could largely be expected given the pilots had initially exhibited a relatively high level of performance pre SIS training (76%). Of more theoretical relevance however, was how novice participants performed on the IFV task pre and post SIS training, with these findings of particular interest in that they can be interpreted in two different ways. On the one hand, a substantial degree of training transfer is evident with performance on the IFV task higher post-training (67%) compared to performance pre-training (47%). Conversely however, accuracy on the IFV task post-training was still only slightly higher than chance (50%) and considerably lower than on any of the stylized (post training – as high as 91%) or realistic SIS training conditions (86%), suggesting a significant portion of the skills gained during the SIS training did not effectively transfer to a more dynamic environment. Indeed a proportion of the gains that are evident on the IFV task could be attributable to practice effects resulting from completing the task pre SIS training.

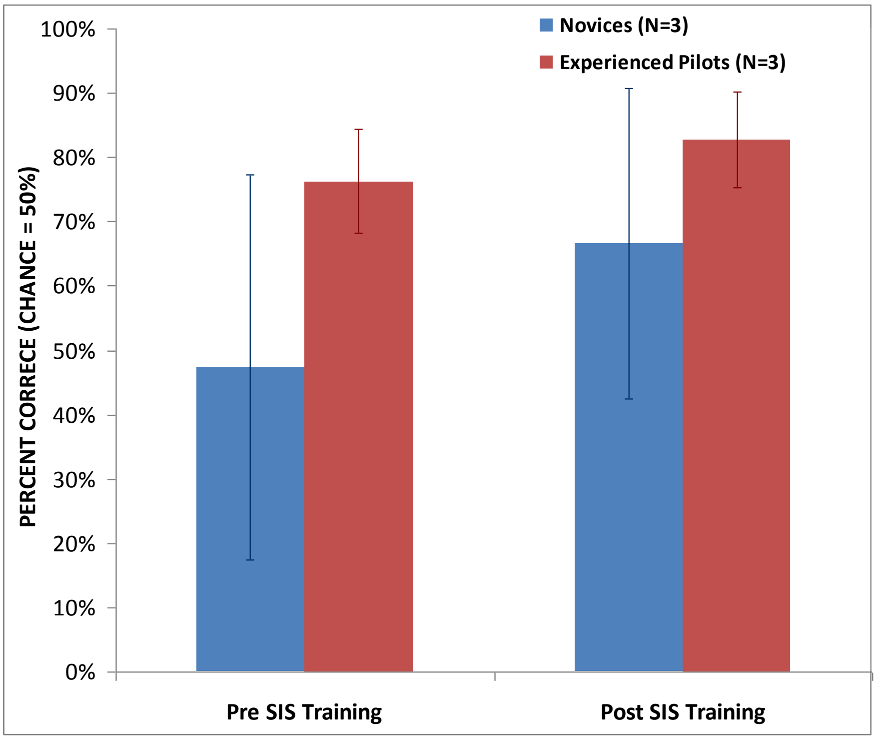

Figure 4. Instrument Failure Video (IFV) Task Accuracy as a function of Novice and Experienced Pilot Participants (Error bars represent Standard Deviation).

These data are only preliminary and further analyses of what is driving this result in terms of cognitive versus perceptual processing is beyond the scope of this paper, yet what is evident from these findings is that despite the level of transfer evident, there remains a disconnect between the cognitive skills and the perceptual skills developed within the stylized SIS training task and how these skills transfer firstly to a realistic SIS task, and then to a more dynamic environment (IFV task). There appears to be an unbridged gap between the skills developed on the stylized and realistic SIS tasks. Considering the similarities in the cognitive demands of these two tasks, this gap is likely to be largely perceptual and hence does not translate perfectly across even superficial changes in task appearance. There seems to be an even greater gap between these static skills and the dynamic skills required to complete the IFV task. As task complexity increases, there is also an increase in the complexity of interactions between the necessary cognitive and perceptual skills, potentially leading to significant issues for performance if these skills are not developed in harmony.

While this study has only provided data from a small number of participants, the development of cognitive and perceptual skills within this type of game-like training tool highlight significant concerns for the potential for such skills to transfer effectively to any real world environment. That is, the gap between the game-like training environment and that of the real world is substantially greater than the gap constructed between static and dynamic training tasks, and as such any potential training transfer is likely to be reduced even further. It is an open question as to how big a role each factor contributing to this gap plays. The verisimilitude of the simulated environment is likely to be only one contributor, the nature of the task being performed and its immediate consequences (i.e., the trainees are not in control of the virtual aircraft nor is there any risk of bodily harm in either of these tasks) are also more than likely to play significant roles.

As highlighted by the current findings, when attempting to develop perceptual or cognitive skills it is not sufficient to train either of these skills in isolation (not to mention training them in isolation from the relevant motor skills). While training components skills has clear benefits, they must be targeted within a meaningful environment that acknowledges the interaction between them. This is a particularly important lesson within serious games and game-like training tools where it is often (albeit not always) acknowledged that psychomotor and perceptual skills are not necessarily well-understood or fully represented, but the importance of developing cognitive and decision-making skills is promoted (Roman & Brown, 2008). In many game-like training tools this may indeed prove to be problematic; and it remains important to demonstrate that the interaction between these skills is correctly developed and is plastic enough to effectively transfer to the practical real world environment. Moreover, the findings from this paper highlight that training transfer can be effectively evaluated within the laboratory environment without the need for expensive real world exercises.

There has been a shift by the Australasian tertiary education sector towards open source Learning Management Systems (LMSs), in part due to the potential for extending and tailoring the systems using community sourced plugins. This paper reports on a comprehensive and systematic evaluation of Moodle extensions based on a six-month cross-faculty project conducted at Macquarie University. Findings included that despite over several hundred plugins and patches being uploaded to the Moodle Community website, the reference group only deemed nine of these as suitable for extending the functionality of the University LMS. The paper also describes the process and instruments that were utilised to evaluate the extensions themselves, which could be of interest to others making decisions about how best to balance the flexibility afforded by open source environment with extensibility within the constraints of complex and diverse institutional needs.

Keywords: Evaluation, Moodle, Extensions, Plugins, Learning Management System

Introduction

In 2010, Macquarie University made the strategic decision to move to Moodle as their Learning Management System (LMS), partly due to the flexibility afforded by an open source license which permits free use, adaptation and restructure of the software (Dougiamas & Taylor, 2003). This flexibility, along with the social constructivist philosophy behind the design of Moodle has contributed to its rapid rate of adoption in the higher education sector (Andrews & Daly, 2008). However, taking advantage of the flexibility to incorporate these features into the LMS poses challenges for institutions. The currently available literature offers a wealth of information about the contribution of LMSs to education but there are still some areas about which little is known. For example, while other studies (Weaver, Nair, & Spratt, 2005) confirm that many teaching staff are primarily focussed on the technical and administrative aspects of using the LMS, what of the affordances of the newer tools to enhance student learning through providing for more diverse learning experiences, timely feedback and positive interaction with staff and peers? When new extensions are developed to further these pedagogical aims .in an open source community where each institution's instance of Moodle is unique, how are new additions and adaptations to be evaluated and selected for sustainability as new versions of the LMS are released?

The aim of this project was to assess a range of extensions for their pedagogical value within Macquarie University's new LMS and to inform selection and adoption of extensions. While the standard version of Moodle comes with a range of valuable features, one of the key advantages of the open-source LMS is the ability to download and install a range of extra modules and extensions that have been developed by educators and technology enthusiasts from around the world. At the time of performing the review (July 2011 to February 2012) there were over seven hundred Moodle extensions that had been uploaded to the Moodle community website (http://moodle.org/mod/data/view.php?id=6009). With such an active community involved in developing and sharing these extensions, sustainable approaches for evaluating these extensions were essential, yet there was little institutional knowledge or guidance from the field about which of these were of pedagogical value. This project sought to identify, categorise, analyse, trial and evaluate Moodle extensions in order to fully capitalise on the educational potential of the Moodle LMS.

Prior to the implementation, extensive research was undertaken to gather feedback from students and staff about what they wanted in the new LMS. A study into Student IT Experiences at the University (McNeill, Diao, & Gosper, 2011) provided clear guidelines about student priorities as flexibility in accessing content, opportunities for communication with their peers and teachers, feedback and convenience offered by online assignment submission. Amongst the key issues for staff were the potential to encourage student engagement with the learning process and efficiencies in managing delivery, assessment, administration and communication with students. Similar themes emerged from the research undertaken by Weaver et al (2005), who found that students who experienced a well-designed unit, with rich resources, timely feedback and good interaction with staff were more likely to report a positive experience with the LMS. These themes were used to inform the initial instance of Moodle, but also the evaluation process for determining which of the myriad of applications would be explored for subsequent integration.

The open source philosophy itself has led to a rapid increase in the amount and type of software available, and the Moodle Community itself actively promotes experimentation, development and sharing of new extensions to be added to the suite. Academics, teachers, instructional designers, system administrators and developers are encouraged by initiatives such as the Netspot Innovations Award to collaborate on developing their ideas. Books further promote these opportunities by inviting readers to ‘customize and extend Moodle using its robust plug-in systems…develop your own blocks, activities, filters, and organize your content with secure code’ (Moore & Churchward, 2010) and articles are available to guide the adaptation of existing Moodle tools (such as (Dodero, del Val, & Torres, 2010). Specific examples of extensions that have been reported in the literature include mobile extensions to increase flexibility of access to Moodle learning environments (Alier, Casany, & Casado, 2007); tools to expedite the addition of content to Moodle sites (; Wilson, Sharples, Popat, & Griffiths, 2009); augmentations to encourage and manage student collaborations (De Lucia, Francese, Passero, & Tortora, 2009; Pérez-Rodríguez, Caeiro-Rodríguez, & Anido-Rifón, 2009) and tools to streamline administrative functions such as managing lab bookings (Ferreira & Cardoso, 2005). Many of the publications about these extensions describe the motivations behind their development to meet the needs of a specific curriculum context and experiences of students or staff in using the tools, yet there is little evidence in the literature about how to evaluate the myriad of new extensions for their potential integration into complex university instances of the LMS, let alone empirical data that assesses their pedagogical quality.

Method

An adaptation of the Communications, ICT, and Organisation (CITO) Framework, developed by Gosper, Woo, Dudley, & Nakazawa (2007) was used as the overarching evaluation framework for the project. The evaluation process also incorporated an expert review dimension to harness the collective experience and insight of the review team.

The first section of the evaluation instrument asked respondents to identify the pedagogical strategies that the tool in question supported, and the ability of the extension to support those pedagogical strategies. The second section asked to rate the utility of the extension in terms of being able to “create connections between people and places”, “create efficiencies in access to content and resources (including improving usability)”, “create new ways to participate, interact, communicate and collaborate”, and “create opportunities to generate, present and disseminate knowledge”. The third section of the evaluation instrument asked respondents to rate the usability of the extension being examined, in so far as it “provides greater access to resources”, “is easy and intuitive to use”, “is reliable with no crashes, failed page-loads or visible faults”, “fast to load and doesn’t have connectivity problems”, “has a screen layout that is clear and intuitive”, and “has a design is modern and inviting”. Both the utility and usability section adopted a seven point Likert item response scale from Strongly Disagree to Strongly Agree. The final section asked respondents to indicate the environmental impact of the extension in terms of the technical skills it required, the breadth of applicability of the extension to the Macquarie context, and whether or not the extension should be included in the University’s new LMS.

The project adopted a five-phase approach to evaluation consisting of the following stages:

- Phase 1: Characterising Moodle extensions
- Phase 2: Identifying tools for further investigation
- Phase 3: Installing identified extensions and establishing system integrity
- Phase 4: Academic evaluation
- Phase 5: Analysing evaluations and forming recommendations.

This method is described in detail below, as it is considered as potentially as useful to the educational community as the results of the study.

Phase 1: Characterising Moodle extensions

This phase involved an initial analysis of the 749 extensions that were in the Moodle extension database at the time. Excluded from further analysis were any extensions that would not function with version 1.9 or later, which resulted in a group of 255 extensions to be more closely examined. Descriptions of the extensions were reviewed and a set of nine categories was developed, which reflected the intended pedagogical strategy of the extensions. These categories are outlined in Table 1, along with the number of extensions in each category.

Table 1 – Pedagogical categories for classifying Moodle extensions

Category	Frequency
Activity	5
Assessment	33
Collaboration	20
Communication	14
Content	13
Course Format	15
Integration	52
Productivity	22
System Administration	43
Usability	38
Total	**255**

In later discussions with technical staff at the University Learning and Teaching Centre, it was decided to exclude Integration and System Administration extensions from this evaluation as they were dependant on the adoption of other systems currently still under evaluation by other projects.

Phase 2: Identifying tools for further investigation

A cross-disciplinary reference group consisting of 41 academic and professional staff from across the University was formed by open invitation to identify the extensions worthy of further investigation and evaluate the extensions that were selected for review. The sorted and categorised list of 255 extensions was distributed via email to the reference group, along with a brief description of each of the extensions. The reference group members were invited on several occasions to identify their "top 10" preferences from the list. Sixteen responses were received and compiled. These responses in addition to insight gained from meetings with key members of the LTC, resulted in a draft short-list of 32 extensions. This list was further reduced to 27 during a meeting with leading representatives of the reference group.

Phase 3: Installing identified extensions and establishing system integrity

A key point of learning from this project is the instability of many community-produced Moodle extensions. Of the 27 short-listed extensions, only 10 could be installed on the evaluation Moodle server with enough stability to be tested. Much of this was owing to insufficient data in the Moodle extensions database; the description of the extensions often indicated that they were compatible with versions 1.9 and above, however they were not compatible with version 2.0. Issues with installation as well as with the initial establishment of the evaluation environment caused a delay of 5 weeks in making the extensions available to the reference group for evaluation.

Phase 4: Academic evaluation

The 41 members of the cross-disciplinary reference group were provided with access to the evaluation Moodle server at the end of October. The evaluation Moodle course provided basic instruction on how to use each of the extensions being tested within it, as well as examples of activities or content created with the extensions. Reference group evaluation occurred on the basis of their hands-on use of the extensions. Sometimes this was as part of small group sessions offered by the project team, but more often through individual experimentation. Feedback was gathered via a link to the online questionnaire. The questionnaire incorporated a utility component, a usability component, and an expert review component (as described earlier in the Methodology section). Feedback was also solicited through informal discussion and interviews.

As the commencement of this phase was delayed due the technical difficulties described above, evaluations did not begin until the end of October. This was a period when many staff were generally focussed on end of semester work such as finalising teaching, marking exams, attending conferences and starting annual leave. Another barrier to participation was the difficulty accessing the evaluation environments from off campus (as a VPN needed to be established). Several strategies were used to increase the number of responses, including lengthening the time the testing environment was available, offering facilitated evaluation sessions, and sending personal and video reminders.

The 82 responses recorded were from participants in a range of faculties and departments. They included:

- Faculty of Arts (1)
- Faculty of Business and Economics (4), including Economics (2)
- Faculty of Human Sciences (44), including Education (27) and Linguistics (2)
- Faculty of Science (7), including Statistics (5)
- Learning & Teaching Centre (22)

These responses included 29 from final year Education students. The participant group was of mixed-ability in terms of their experience with using Moodle. Apart from the Education students (none of whom had used Moodle before), only 4% of participants indicated they were beginner Moodle users. The rest were Intermediate (21%), Experienced (38%), or Advanced (37%) users.

Phase 5: Analysing evaluations and forming recommendations

Reference group responses to the questionnaire were compiled and summarised for each extension in terms of the perceived capability and usability of each tool. Response summaries also incorporated the pedagogical strategies that respondents felt each extension supported, and qualitative feedback about the ability of each extension to do so. Reported data also included the average likelihood with which respondents would use the extension in their units, and a summary of respondents' overall recommendation about whether the extension should be integrated into the University LMS.

Results

This section provides a summary of the cross-disciplinary reference group responses for each of the extensions that were evaluated. As the aim of this project was to determine the suitability of individual extensions designed for different purposes, direct comparisons between extensions have not been made. The following extensions were evaluated (number of respondents for each tool type in brackets):

1. OU Wiki (17)
2. Forum NG (14)
3. OU Blog (10)
4. Question Type: Concept Map (10)
5. Question Type: Drag-and-drop matching (9)
6. Team Builder (8)
7. Drag and Drop File Upload (4)
8. Progress Bar (3)
9. Course Format: Grid (1)
10. Checklist (1)

Feedback from the respondents is outlined below. A brief description of each tool is provided at the beginning of each section to foreground the responses. This is followed by respondent perceptions of the pedagogical strategies that the extensions supported, the ability of the tool to support the pedagogical strategies, and qualitative observations regarding utility and applicability. This is then followed by a graphical summary of respondent perceptions relating to the capabilities and usability of the extensions for tools that received eight or more reviews from reference group members.

1. OU Wiki

Created by the UK Open University, OU Wiki is a "simple, easy to use alternative to standard Moodle wiki."
In total, 17 participants reported on the OU Wiki. Respondents reported that the OU Wiki supported group-work and/or collaborative learning (17), peer-learning (15), creation and/or delivery of media rich content (8), formative assessment and feedback (6), summative assessment (2), differentiation of learning activities and/or outcomes (1), project work (1), online tutorial activities and discussion (1), create a personal or unit-based database (1). Of the respondents, 12 rated the OU Wiki as Excellent or Very Good for supporting pedagogical strategies and 16 recommended it for inclusion in the University's Moodle instance. Evaluators rated OU Wiki as being highly capable of creating opportunities to generate, present and disseminate knowledge as well as creating connections between people and places.

OU Wiki was also ranked highly in terms of usability, in particular for ease of use and intuitive interface. However, comments indicated evaluators found concurrent editing with other users problematic. Barriers to use indicated included lack of familiarity with the concept of a wiki and technical skills required by both teachers and students. Functional limitations noted included a lack of a left-hand navigation menu and the ability to comment on posts. Qualitative comments on OU Wiki ranged from "Great for exploring knowledge and problem solving and just general collaborative communication" to "it can only be utilized when students have the sufficient technical knowledge."

2. Forum NG

Alternative forum for Moodle with AJAX features.
Responses were gathered on Forum NG by 14 participants. Respondents reported that this extension supported group-work and/or collaborative learning (11), peer-learning (11), administrative efficiencies (7), reflection/reflective learning (6), formative assessment and feedback (5), simulation, case-base of problem-based learning (1), online debate (1), group projects (1), and peer assistance (1). A total of 11 participants reported that it was Very Good at supporting pedagogical strategies, particularly in terms of its capabilities to improve access to content and resources. Of the respondents, 12 reported that they would recommend it for inclusion in the University Moodle (4 conditionally).

Respondents' impressions of the overall functionality of Forum NG were largely positive and features. An example of a positive response included: "Allows better access to content for assessment: view by student; students can provide permalink to submit best posts. Better personal management of posts via flagging. Finer management control by Convenor". Forum NG was also ranked positively in terms of usability. However some reported dissatisfaction with layout and styling as well as some inconsistencies with how Forum NG functioned, for instance commenting that "Styling needs work. We had a problem where one thread was visible to some but not all. Print button for view by user would be useful". Two respondents provided negative feedback on reliability, indicating they may have experienced faults.

3. OU Blog

Created by the UK Open University, OU Blog is an enhanced user and course blog.
The OU Blog was evaluated by ten participants, who reported it as useful to support reflection/reflective learning (10), peer-learning (9), group-work and/or collaborative learning (6), creation and/or delivery of media rich content (6), formative assessment and feedback (5), simulation, case-based or problem-base learning (3), summative assessment (3), administrative efficiencies (1), and documenting processes (1). All ten of the respondents deemed it to be worthy of inclusion in the University LMS. Evaluators rated OU Blog and being highly capable of creating opportunities to create connections between people and places as well as create efficiencies in access to content and resources.

Respondents found OU Blog easy to use with a clear and intuitive layout; "Standard blog that is easy to use and hence attractive option for many academics". One respondent described how the layout was more like a "blog-like forum", rather than being similar to commercial blogs. The lack of export functionality was noted as a significant drawback. Another negative comment related to media upload, particularly: "I couldn't find a means of uploading imgs - could link to img URL."

4. Question Type: Concept Map

A new type of question for Moodle quizzes that requires students to create and submit a basic concept map as their answer.
The ten respondents who evaluated the Concept Map question type felt that the supported formative assessment and feedback (7), summative assessment (4), reflection/reflective learning (3), differentiation of learning activities and/or outcomes (2), simulation, case-based or problems-based learning (2), creation and/or delivery of media rich content (1), group-work and/or collaborative learning (1), visual formative or summative online representation (1), and critical thinking (1). The majority of people believed this tool was 'good' at supporting these pedagogical strategies. Participants did not rank the Concept Map Question Type highly in terms of collaboration capabilities, however 5 respondents agreed that it created opportunities to generate, present and disseminate knowledge. Qualitative feedback about the utility of the tool varied from luke-warm ("needs effort for limited return" to valuing the diversity it offered ("it's a different way to engage students").

In terms of usability, the Concept Map extension was ranked highly in terms reliability and speed, though some respondents rated its design negatively For instance respondent comments included "it is not obvious at first (at least to me) what to do, it needs more specific instructions at the top" and "there are better mind mapping interfaces about." Some experienced faults such as content created not saving or being recorded.

5. Question Type: Drag-and-drop matching

A new type of question for Moodle quizzes that creates the lists of terms to be matched by dragging and dropping one onto the other.
Drag and Drop Matching was evaluated by nine participants. Most rated is as successful for formative assessment and feedback (6), reflection/reflective learning (6), followed by summative assessment (5), administrative efficiencies (1). Overall, respondents rated the capabilities of the Drag and Drop Matching Question Type to be moderate, with around a third of respondents strongly disagreeing with its capacity to support any of the target capabilities. However all nine recommended it for inclusion in the University Moodle.

The Drag and Drop Matching Question Type was ranked highly in terms of usability, in particular for reliability and speed. Respondents reported minimal difficulties with using this question type but also indicated its value would be minimal, but potentially nice to have. Comments included "Allows students to review their knowledge. Does not rely on students typing and possibly misspelling a word" and "the exercise in itself is a formative assessment tool. It has the danger of being used for summative assessment."

6. Team Builder

Intelligently builds groups based on criteria specified by an instructor and responses given by students.
Eight of the respondents evaluated Team Builder These respondents felt Team Builder supported group-work and/or collaborative learning (8), peer-learning (4), formative assessment and feedback (3), creation and/or delivery of media rich content (3), administrative efficiencies (3), simulation, case-based or problems-based learning (2), reflection/reflective learning (1), summative assessment (1), differentiation of learning activities and/or outcomes (1), and group work assignments (1). Of these respondents, seven recommended it for inclusion in the University Moodle instance. Respondents indicated Team Builder was suited to collaborative learning and connecting people and places. Team Builder was ranked moderately in terms of performance, with the basic requirements of being reliable and fast to load being met.

Respondents found Team Builder difficult to use and were unsure about its ability to actually create teams. For instance, one respondent commented "seems more trouble than it's worth". However others could see its niche value, commenting "Not many people would use this, but for a select few it may make their life much easier".

7. Drag and Drop File Upload

Drag and drop one or more files directly from your desktop into a Moodle course.
The four respondents who evaluated Drag and Drop File Upload, felt that it predominately supported administrative efficiencies (2). One commented that "drag and drop is more administrative, than pedagogical… it is a workflow [tool]". One person felt it could be used to support group-work and/or collaborative learning, reflection/reflective learning. Of the respondents, three recommended for inclusion in Moodle.

As Drag and Drop File Upload is primarily an administrative tool, it was not ranked highly in terms of pedagogical capability. Respondents indicated functionality problems with using Drag and drop File Upload, with one not able to get it to work at all (“I could not get this to work using Mac OS 10.6.8 and Firefox 7.0.1”). However those who were able to use the tool rated it positively.

8. Progress Bar

A block that allows students and teachers to track student progress in all courses from the front page as well as from within each course via a graphic bar.
Three respondents evaluated the Progress Bar and rated it as supporting reflection/reflective learning (1), formative assessment and feedback (2), administrative efficiencies (1), performance monitoring (1), and motivation (1). All three recommended it for inclusion in Moodle. Feedback on the pedagogic capabilities of Progress Bar was mixed, owing to its predominantly administrative and motivational functionality.

Progress Bar was ranked highly in terms of usability, in particular for its intuitive interface. No specific faults or limitations were reported. Comments on Progress Bar included “I can see students really responding to the task oriented nature of the tool - "this is what I need to do next."

9. Course Format: Grid

An alternative course format that presents topics as images laid-out in a grid.
This extension was rated by only 1 respondent, an advanced staff user. Feedback provided was positive in terms of usability but largely negative in terms of pedagogical value. The respondent commented that “Since it is just providing an alternative interface option, then why not include it (as long as it is reliable).” In response to whether or not they would use it in their own teaching, the responded indicated: “Probably not, I like to be able to lay the content out directly so students can see the whole unit.”

10.Checklist

Allows student progress against a set of activities within a course to be tracked.
Only 1 staff response was received for Checklist, with 1 additional response from a student. Feedback was similar to that for Progress bar in terms of pedagogical application, however it was reported as less usable and with more limited functionality than Progress Bar.

Summary of Capability and Usability Ratings

Figure 1 presents a summary of the feedback on the evaluation of the capabilities of each extension, presented as an average for each. Those extensions with fewer than eight evaluations have been omitted from the table. OU Wiki, OU Blog and Forum NG were all rated highly for their capabilities to generate, present and disseminate knowledge, create new ways to communicate and collaborate, create efficiencies in accessing content and creating connections.

A summary of the responses relating to the usability of each extension types is included in Figure 2, again with average ratings presented. As with the Capability ratings, the more established collaborative tools (OU Wiki, Forum NG, and OU Blog) received the most consistent ratings, though the Drag-and-drop matching and Team Builder extensions rated highest in terms of speed and reliability.

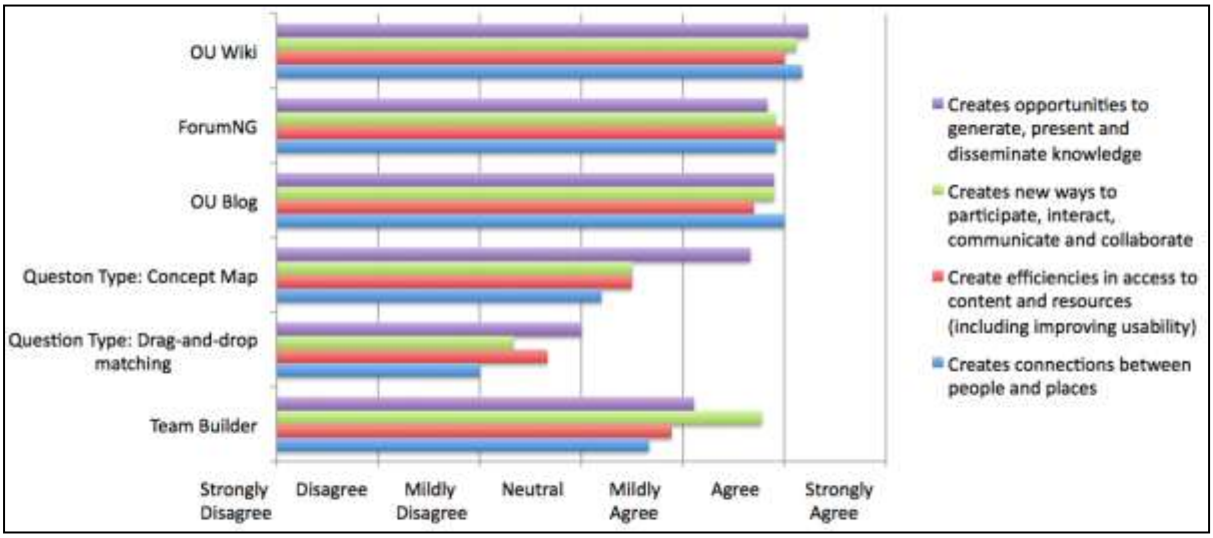

Figure 1: Respondent perceptions of the capabilities of evaluated extensions

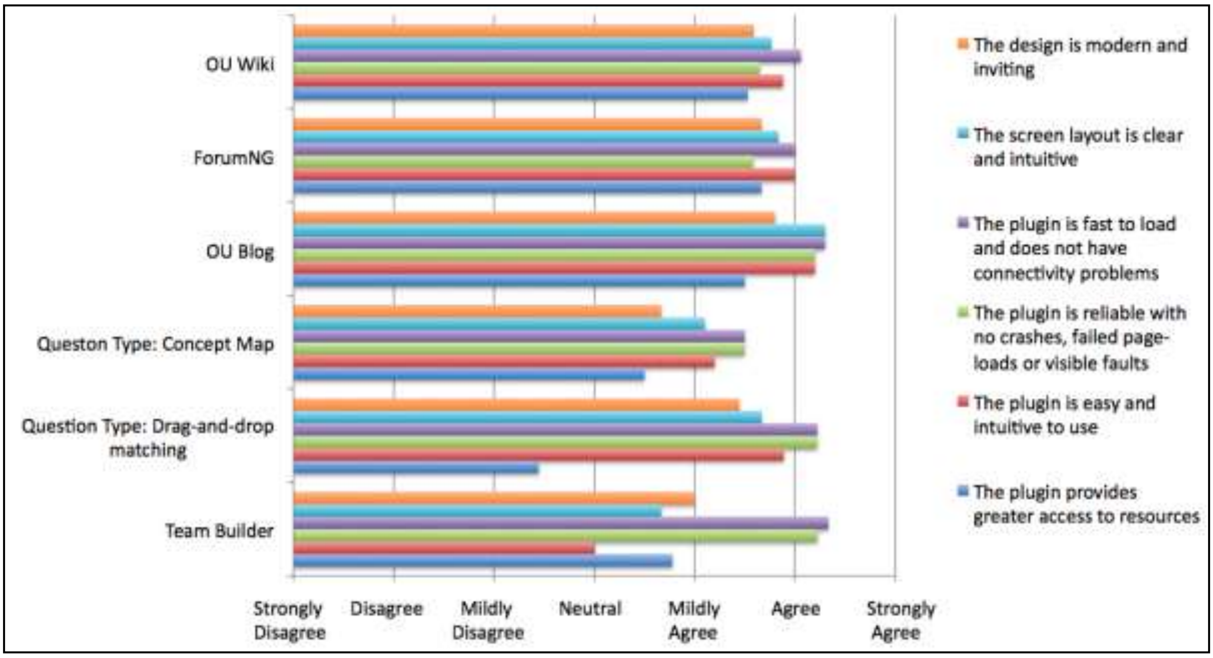

Figure 2: Responded perceptions of the usability of evaluated extensions

Discussion

Based on feedback from the cross-disciplinary reference group, Table 2 summarises the final recommendations for including evaluated extensions into the Macquarie University LMS. The extensions rated most highly by the participants were the tools most typically associated with LMS environments, such as wikis, forums and blogs and are useful in encouraging student communication and collaboration. These elements were rated as important in the University surveys on student IT experience. Given that the respondents were volunteers who needed to spend time out of their normal workload to evaluate the extensions, it might be that they selected tools according to their priorities and began with the most important. This could also suggest that the name of the tool can an issue; if the name did not provide a clear indication of what the tool did, then it may not have been prioritised.

Table 2 – Extensions recommended for inclusion in the University LMS based on respondent feedback

Extension	Would use in teaching	Average applicability score	Include in iLearn	Overall recommendation
1. OU Wiki	13 Yes 3 Maybe 1 No	78%	16 Yes (2 conditional) 1 No	**Include**
2. Forum NG	10 Yes 2 Maybe	90%	12 Yes (4 conditional)	**Include**
3. OU Blog	8 Yes 2 Maybe	78%	10 Yes	**Include**
4. Question Type: Drag-and-drop matching	5 Yes 4 Maybe	71%	9 Yes	**Include**
5. Question Type: Concept Map	4 Yes 5 Maybe 2 No	62%	7 Yes 2 No	**Include**
6. Team Builder	3 Yes 4 Maybe 1 No	69%	7 Yes (2 conditional) 1 No	**Include**
7. Drag and Drop File Upload	2 Yes 1 Maybe 1 No	73%	Yes (3 conditional) 1 No	**Include**
8. Progress Bar	2 Yes 1 Maybe	94%	3 Yes	**Include**
9. Course Format: Grid	1 No	100%	1 Yes (conditional)	**Include**
10. Checklist	1 Yes 1 Maybe	76%	2 Yes	**Do not Include**

Although there are several hundred extensions available on the Moodle Community website, only a small handful were deemed suitable for Macquarie University's Moodle 2.0 LMS. One of the attributes of community-based open-source software is that extensions are often not maintained or upgraded in step with the core system development cycle, which has serious implications for the sustainability of the extensions. Many are rendered obsolete when a new version is released. The Moodle Community website has recently reorganized their main extensions page to account for this, back-grounding outdated plugins.

This project only performed a pedagogical evaluation from the teachers' perspective. Participants rated the extension in terms of being able to "create connections between people and places", "create efficiencies in access to content and resources (including improving usability)", "create new ways to participate, interact, communicate and collaborate", and "create opportunities to generate, present and disseminate knowledge", with those most familiar tools such as OU Wiki, Forum NG and OU Blog being rated most highly, Further exploration is needed to capture student perspectives. Testing of the stability, scalability and technical environmental fit would need to be undertaken before any of the plugins identified as valuable were integrated into the University LMS. The technical testing should at least include a focus on:

1. Accessibility
2. Confidentiality and security of data
3. Intellectual property and development potential
4. Scalability for use large or small units
5. Administrative functionality
6. Quality of support documentation

There is also an inherent tension between the flexibility of the open source nature of Moodle and the complex and unique instances that are implemented in each university, providing a stark reminder of the need for comprehensive testing of open-source developed extensions before full release.

One limitation of this study was that the rate of participation from testers was lower than anticipated. This was owing to delays of establishing the evaluation environment that pushed the evaluation phase closer to the end of semester when fewer staff were available. Simplified off campus access to the testing and evaluation environment would also have helped improve response rates. A larger sample of responses would have enabled more reliable conclusions to be drawn and may have resulted in different recommendations being formed. The time-poor nature of academics and the high level of engagement required for them to explore new extensions and evaluate them for possible use in their specific teaching contexts is an ingoing challenge. While the notion of a community approach to developing and evaluating new tools is a noble principle, it is reliant to a large extent on the time and goodwill of busy academics. In addition to this exploration from within specific curriculum contexts, the effective evaluation also requires input from central units to ensure sustainability and scalability from a university-wide perspective. Add to this the technical input required to judge the feasibility of the implementation and the scale of the evaluation process becomes apparent.

This study has already informed the adoption of two extensions within the University's new LMS – OU Blogs and OU wikis. These were seen as valuable additions and after technical testing were installed for use in Semester 1, 2012. Apart from determining a range of pedagogically appropriate extensions for the University's LMS, the functional analysis tool is another positive output of this project. This built on previous evaluation tools and can be used as an evaluation instrument for other technologies in other projects. While the specific extensions analysed in the study will eventually become obsolete, the functional analysis tool can be used independently of particular LMS platforms or versions thus enhancing sustainable development of learning technology platforms. Another benefit of this project was the unification of the University's educational community behind the implementation of the new LMS. Over 41 academics expressed interest in this project and many combined forces to contribute to the evaluation. This team offers an ongoing working party to evaluate new extensions and feature requests as they emerge. The momentum of this network is being continued through the Macquarie University Learning Technology Research Cluster.

Virtual worlds: Not the final frontier for games-based nursing education

Grant Meredith
University of Ballarat

Leigh Achterbosch
University of Ballarat

Kylie Turville
University of Ballarat

Sita Venkatraman
University of Ballarat

Virtual worlds present frontiers of promise for the ever evolving venture of pedagogical development, trial and embracement. Of late there have been large pushes into these worlds in terms of health-based education for students and early practitioners. Virtual worlds seem to be the next logical jump into nursing education and can offer a range of simulation benefits. But these worlds do not appeal to all students, can be complex and expensive to develop and interact within. Other game-like avenues exist though and have not been explored thoroughly enough to date. Such genres like puzzles games, management style games and surprisingly first person shooters already have titles and game mechanics which have been somewhat adapted to nursing education but could easily be more thought out and developed to suit. This paper outlines the two major gaming audience types to be considered and then explores a range of options for nursing education beyond virtual worlds.

Keywords: nursing education, serious gaming, computer-based learning; virtual worlds.

Introduction & purpose

Virtual worlds like Second Life and OpenSim have recently generated a lot of interest and developments concerning simulation and education across many disciplines. Their three dimensional environments, modern games-related interfaces and controls make them intuitive avenues of educational approaches for sections of the growing gamer student demographics. Universities just like ours, the University of Ballarat, have invested resources, time and effort into developing and evaluating virtual nursing education platforms with success and proving the educational viability of such approaches to both the student and lecturer (Miller, Lee, Rodger, Meredith & Peck, 2010; Meredith, Miller & Simmons, 2012). But virtual worlds themselves are somewhat expensive to develop from scratch and at times are daunting for both the developer to create and participate within (Eno, Stafford, Gauch & Thompson, 2011). Lost amongst all the hype of these newly embraced virtual platforms is the fact that other gaming genre platforms have existed for many years prior to the virtual genre. These existing genres could be equally beneficial and perhaps even more simply embraced by many student nurses in future educational games. Socially, culturally and technologically computer games have significantly impacted modern society, including education, and long established genres continue to influence this trend (Kapp, 2012). We wished to explore these existing and somewhat older formats because some of these genres already have marketed health and nursing related games that could be used as inspiration to build more developed, enjoyable and educational games and simulations for student nurses. The purpose of this paper is to outline a range of different player types to be considered when conceiving and designing educational games for learning in the future. This paper will also outline different gaming genres with existing nursing/health related games and to offer some related educational options beyond virtual worlds.

Catering to different audiences

Developers of nursing educational games, actually any games in general, have to consider the variety, skills and expectations of their audiences. Perhaps some nursing students rarely play video games, while others may own multiple video game consoles or operate a personal computer with varied game genre interests. By nature of preferred genre not all students are used to the standard controls and mechanics of a virtual 3D environment. Perhaps some enjoy quick bouts of Tetris on their mobile phone, while others enjoy huge immersive worlds with expansive narratives to explore on their high definition monitors. Perhaps some put in many hours a day gaming and others maybe little to no time per week at all. To help distinguish these two audiences, they can be classified under two very broad categories, the casual gamers and the core gamers. It is important to know the differences in broad gamer types in order to appreciate the common related genres and games styles preferred. It is also important to understand these gamer types in order to develop, trial and market related games.

Casual gamers tend to enjoy games that can be played in short bursts, on a wide variety of devices, such as the personal computer, notebook, tablets, pads, and mobile devices. Casual gamers often do not invest large amounts of time into a single title and often stop playing once bored or frustrated (Adams, 2010). These games are usually just a small download to the user's device ready to play in minutes, or can be played directly in the web browser using the Java application or Adobe Flash player (Kultima, 2009). These games involve less complicated controls and typically less complex game mechanics (Kuittinen, Kultima, Niemelä Johannes, & Paavilainen, 2007). A distinctive example would be Firemint's Fruit Ninja or Zynga's extremely popular FarmVille available as a Facebook application (Andersen, Liu, Snider, Szeto, & Popovi'c Zoran, 2011).

Core gamers, on the other hand, are a game audience that expect and require depth and hours of evolving game content (Bosser & Nakatsu, 2006). These gamers tend to take game playing seriously and spend large amounts of time and at times money dedicated to each game they play (Fritsch, Voigt, & Schiller, 2006). The games catering to this audience usually cannot be played in short bursts and often involve complex mechanics and rich branching narrative designs. Core gamers feel the need to spend time mastering the game's challenges and accomplishing set goals (Bosser & Nakatsu, 2006).

Instinctively each broad gamer type presents the developer and educator with a unique set of challenges and demands to consider. It cannot be assumed that all your students, in this case nursing, will be satisfied and intuitively understand a detailed virtual world environment to contend with. Next we will explore some different game genres that these two particular audiences enjoy playing, outline health related games within each and discuss how nursing education could be adapted to these alternative genres.

Alternative genres

Puzzle games

This video gaming genre emphasises the solving of puzzles and tends to focus on testing the player's puzzle solving skills such as logic, strategy, pattern recognition, sequence solving and word completion (E. Adams & Rollings, 2006,). Common puzzle games include Solitaire, Tetris and Mahjong (Thompson, Berbank-Green, & Cusworth, 2007). More recently Angry Birds has become a well-known commercially successful physics based puzzle game, available on a large variety of platforms and mobile devices (Cramer, 2011; Middleton, 2011). Many puzzle games with their short bursts of challenge and interest are very appealing to casual gamers.

The puzzle game genre lends itself to a variety of different styles of games that could be adapted for nurses as training tools. Tablets and mobile devices would pose interesting and convenient platforms for taking the blood pressure and monitoring the signs of a virtual patient. This could also be true for visualizing medical equipment monitors, and for the player/nursing student to assess what is going on. In a sense piecing together the feedback, signs and signals of a virtual patient and being then able to assess the scenario. Surgical nursing games would make great candidates for the puzzle genre, such as assisting surgeons, using the correct tools and keeping up with aseptic technique practices. An example of an existing game that could be adapted for surgical nursing is Pet Pals: Animal Doctor, developed by Legacy Games for PC and Mac (Legacy Games, 2012). In this game players must diagnose and treat animals in a realistic simulation using many medical instruments.

The puzzle genre would also be ideal for a nursing assessment game where the nurse has to do a full body assessment (cardiovascular, respiratory and reproductive as a few examples) to collect enough data for a diagnosis to be made, or to perhaps even work out drug requirements and calculations. Perhaps a player would be given the ability to ask questions of the patient to form a medical history. This game could focus on medical patients with different symptoms, or could be more specific such as the psychiatric patients for the mental health nurse.

Time management games

Time management games usually focus on time as a critical resource to be aware of and control other resources within. The player must spend their time wisely performing the tasks involved to complete each level, stage, or assignment for example. The player could be given a critical task that needs to be done immediately and also tasks that may be set aside for a more appropriate time. It is all up to the player to manage the time spent efficiently. Big Fish Games and GameHouse Games have a large variety of time management games. This would pose perfect scenarios for a student nurse learning how to manage multiple patients and critical tasks. These games could be crafted to suit either casual or core gamers depending on length and complexity of the task at hand.

More specific to nursing, Alawar Entertainment developed a game called "Hospital Haste" which is available on PC and in the iTunes store. In Hospital Haste the player must direct a nurse in diagnosis, treatment, and curing her patients. Time management is used to direct the nurse which patients require priority, in order to send all patients home healthy (Alawar Entertainment, 2012). Merscom, the developer of "Hospital Hustle", went a little further in that the player must manage the ward as well as a nurse. Placement of treatment devices and beds is as much a priority as directing the nurse to diagnose and treat patients. Adaptation of such a game could be made to suit specific and modelled needs of a real life hospital and style of ward.

Real-time strategy games

The typical real-time strategy game focuses on manoeuvring warfare units around a battlefield and engaging in combat with hostile opponents. They include building and defending structures which are capable of producing additional units, and using those units to destroy the opponent’s structures and units (Adams, 2006; Metoyer et al., 2010). This genre is where we move away from the casual gamer and start focusing on the core gamers. Rather than played in short bursts, the real-time strategy genre usually involves skill and dedication in order to master its many mechanics (D. Adams, 2006). The strategy involves managing resources to build structures and units, while playing both defensively and offensively to win the level.

While usually themed around war and combat, the genre design of real-time strategy could be adapted to fit well within the realms of a hospital or ward. The player would control nurses rather than warfare units, and build different medical rooms and place medical equipment, rather than combat structures. In this sense the patients become the nurse’s problem to fix, in the same way the combat units problem is this hostile opposition. There are many possibilities within this scenario, conceivably the player could play as the head nurse and manage a team of nurses on the ward in a real-time scenario. Or perhaps the player could control each nurse individually in a ward, able to change between them at will, on a real-time basis with each level getting progressively more difficult to manage. An example of this would be the early levels managing one nurse with few patients, and later levels managing multiple nurses with a completely full ward of patients. This genre would also suit the education on emergency medical teams quite well.

These suggestions have similarities to an older PC strategy game called "Theme Hospital" developed by Bullfrog Productions. In this game the player manages a hospital - building the layout, managing the doctors, specialists, nurses, and even janitors, in order to run a successful hospital.

First person shooter games

This genre would most likely be overlooked as something that could be redeveloped for nursing education, as at its core the genre involves the shooting of and the killing of people, aliens or monsters for example, through the eyes of the hero character (Cardamone, Yannakakis, Togelius, & Lanzi, 2011). But this genre has been used in the past by government bodies in producing training software, for example the U.S. Army created the promotional game called "America's Army" (da Silva Simoes & Ferreira, 2011). Could this be taken one step further to development of software that trains military medical staff for field-based exercises? Battlefield environments require a lot of medical care, and this game genre may be adaptable to that specific field of nursing, or perhaps a more generalised approach to simple exploring and interacting with a virtual hospital. Once again, this type of genre would cater to a core gamer, as the player usually requires good reactions and reflexes along with a multitude of input devices such as mouse and keyboard simultaneously in use by the player. In other words the learning curve is much more difficult than a casual game.

Moving away from the battlefield, the first person viewpoint could make an excellent immersive tool for a nurse, especially in a busy ward such as the emergency ward. In this the player must perform emergency nursing triage, with the objective of performing data collection and making the decision of the category the patients have to be seen in (1 = Immediate / Life Threatening, 5 = Less Severity). In this ward, the wrong decision can be fatal.

Conclusion

Although virtual worlds are currently highly fashionable to develop and research within at this moment in time in terms of education, in this case nursing education, it is clear that differing games-based avenues exist and have existed for a long time. Yet through all the hype these other existing genres and platforms have been largely overlooked. Overlooked options, yet they are long established mediums through which people have played and interacted with for many years. We conclude that more attention is required for nursing education purposes throughout avenues other than virtual worlds. Genres such as puzzles, strategy and time management lends themselves so cleanly to being adapted and thought out for health-based educational games. In the future, educators, researchers and developers need to spend more focus and attention to these alternate avenues to educate and train health professionals in perhaps ways which are more accessible, more intuitive and even more cost effective forms than what virtual worlds present.

Do not let hype and trendy focus dictate the direction of education, because in reality there have been such rich pedagogical avenues overlooked or at best lightly developed. We cannot expect a varied student audience to be highly effective within such a complex medium such as virtual worlds and this will hamper future directions of development and embracement of methods. We need to carefully understand the audience, their requirements and importantly their pre-existing experiences with gaming environments to be able to shape the future of health-related interactive education. Virtual worlds are an answer, but not the only answer and we should not be blinkered into believing so. We must continue to dream up, develop and explore future educational methods and worlds, but not at the expense of under developed existing ones.

Early identification of students at risk of failing

John Milne
Massey University

Lynn M Jeffrey
Massey University

Gordon Suddaby
Massey University

Andrew Higgins
Andrew Higgins Ltd

This paper outlines how teachers can use the learning management system (LMS) to identify at risk students in the first week of a course. Data is from nine second year campus based business courses that use a blend of face-to-face and online learning strategies. Students that used the LMS in the first week of the course were more likely to pass. For the rest of the course the pattern of usage is then largely similar for students who pass and those that do not pass. This paper identifies how a LMS can identify at risk students in the first week of the course and provides some strategies to motivate these students.

Keywords: At risk students, learning management system, early intervention, student success

Introduction

Tools are available to track participation in a learning management system (LMS). Teachers can get reports in a LMS on who has or has not used the LMS or some aspect of it. For instance Moodle keeps a log of each screen that the students visit. Teachers can then filter results by student name, date, activity and action. More sophisticated tools are available that allow the teacher to visualise clusters of student usage data that allow the teacher to look at student performance or behaviour (Hall et al, 2009; Hangjin & Almeroth, 2010; Lee, Chen, Chrysostomou, & Liu, 2009). Many of these tools are complex and are not easy for the teacher to use (Romero, 2011).

A number of papers have explored the association of LMS usage and student success. Cocea and Weibelzahl (2009) used data mining techniques to examine student behaviour that predicted disengagement. They found that student behaviour of time spent reading pages and taking tests were associated with student engagement. Altinay and Paraskevas (2007) found that those who rarely post to discussion forums are at risk of failure. Baugher, Varanelli, and Weisbord (2003) found that consistency of LMS use was a better predictor of success than total hits. Buglear (2009) found that some students who drop out do not use the electronic system so that this may also be a good indicator of students who are at risk of not completing the course.

A pilot study suggested that there was an association between students' use of the LMS and final grades. Students who use the LMS in the first week of the semester were more likely to pass. This paper aimed to test this association with data from another eight courses. Patterns of usage over the semester were examined to identify differences between students who pass and those who fail. This data is discussed using the student engagement literature of Kahu (2011) and Jeffrey, Milne, Higgins and Suddaby (in press).

Methods

The LMS logged students' usage over the semester for nine campus-based courses involving 703 students. The courses offered students campus-based lectures and tutorials with a LMS that had resources, forums, assignment upload and feedback facilities, and in some courses, online quizzes. The number of times a student downloaded a LMS resource or activity was recorded and the results summed for each week over the semester. The usage patterns over the semester are presented for students grouped by their overall course marks. Four groups were tracked based on final marks. These were students who achieved an A or B pass, C pass, fail, or did not complete. The distribution of marks across the categories was not even. On average across nine courses the percentage of students in each category is: 50% obtained an A or B; 30% obtained a C; 11% failed; 9% did not complete. The class sizes ranged from 23 to 147 with a mean of 78.

The data from the first week of the course for the students who completed the course was analysed. There were 658 students who sat the final exam. Those who did not complete were removed from the analysis because the wide range of non-teaching related reasons for withdrawing were considered to cloud the issue. Students who complete the course show determination and perseverance that were considered likely to respond to teacher interventions. The students were grouped by those that: did not use the LMS; used it for 1 to 5 page views; used it for 6-20 page views or for over 20 page views. The percentage who passed the course were identified in each category and associations tested by a chi square.

Results

The usage for the first week of the semester was compared to the number of students who passed the course (Figure 1). Successful students were more likely to use the LMS in the first week for both the pilot (ChiSq=20.4, 3df, $p<0.001$) and main trial (ChiSq=19.5, 3df, $p<0.001$).

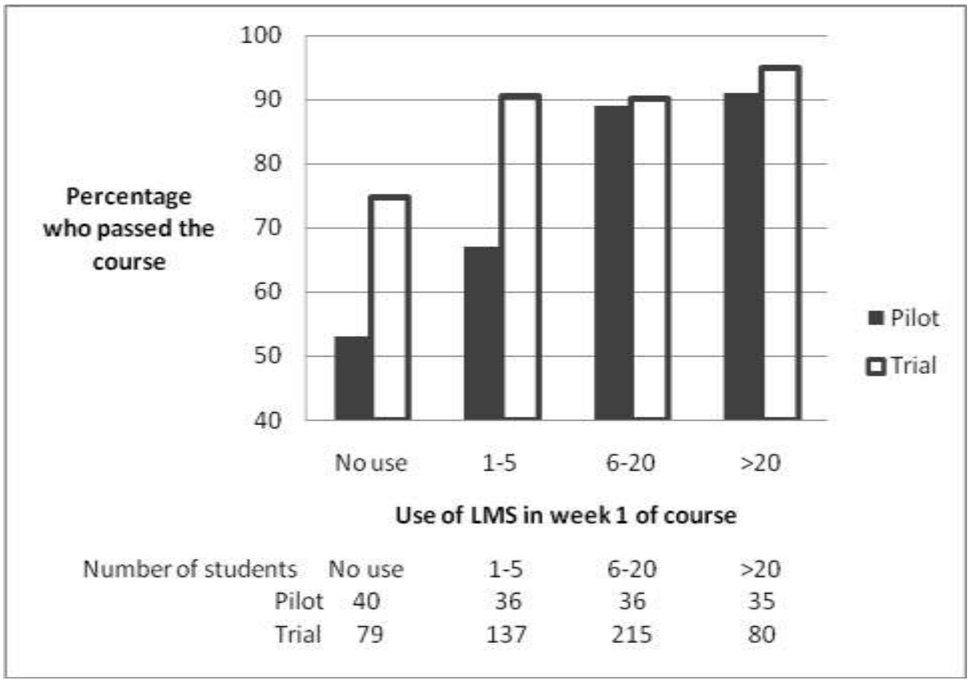

Figure 1: The number of students who passed the course grouped by use of the LMS in the first week of the Semester for the pilot and trial courses

The pattern of LMS use is provided in a sample of six courses (Figure 2). These graphs are characterised by peaks and troughs of activity with the peaks coinciding with the assessment. Week 7 and 8 were midterm breaks which did associate with a drop in activity in some courses but not all. Courses with assessment that is due immediately after the break had peaks of activity during the break. All but one course had a final exam that was associated with a final burst of activity. Course 5 (Figure 2) was internally assessed with a marked drop off of activity after the final assessment report.

The main difference in patterns of use between students who passed and those that failed relates to the very early stages of the course where students who fail are distinctively lower in online activity. It may be that after this stage, students are unable to catch up or that they have missed critical information or orientation to the course. This may mean that the first week, or the very early part of the course is critical to success and that later in the course measures such as total hits does not identify students who are struggling. Students who did not complete the course generally had lower use although some did use the LMS throughout the course.

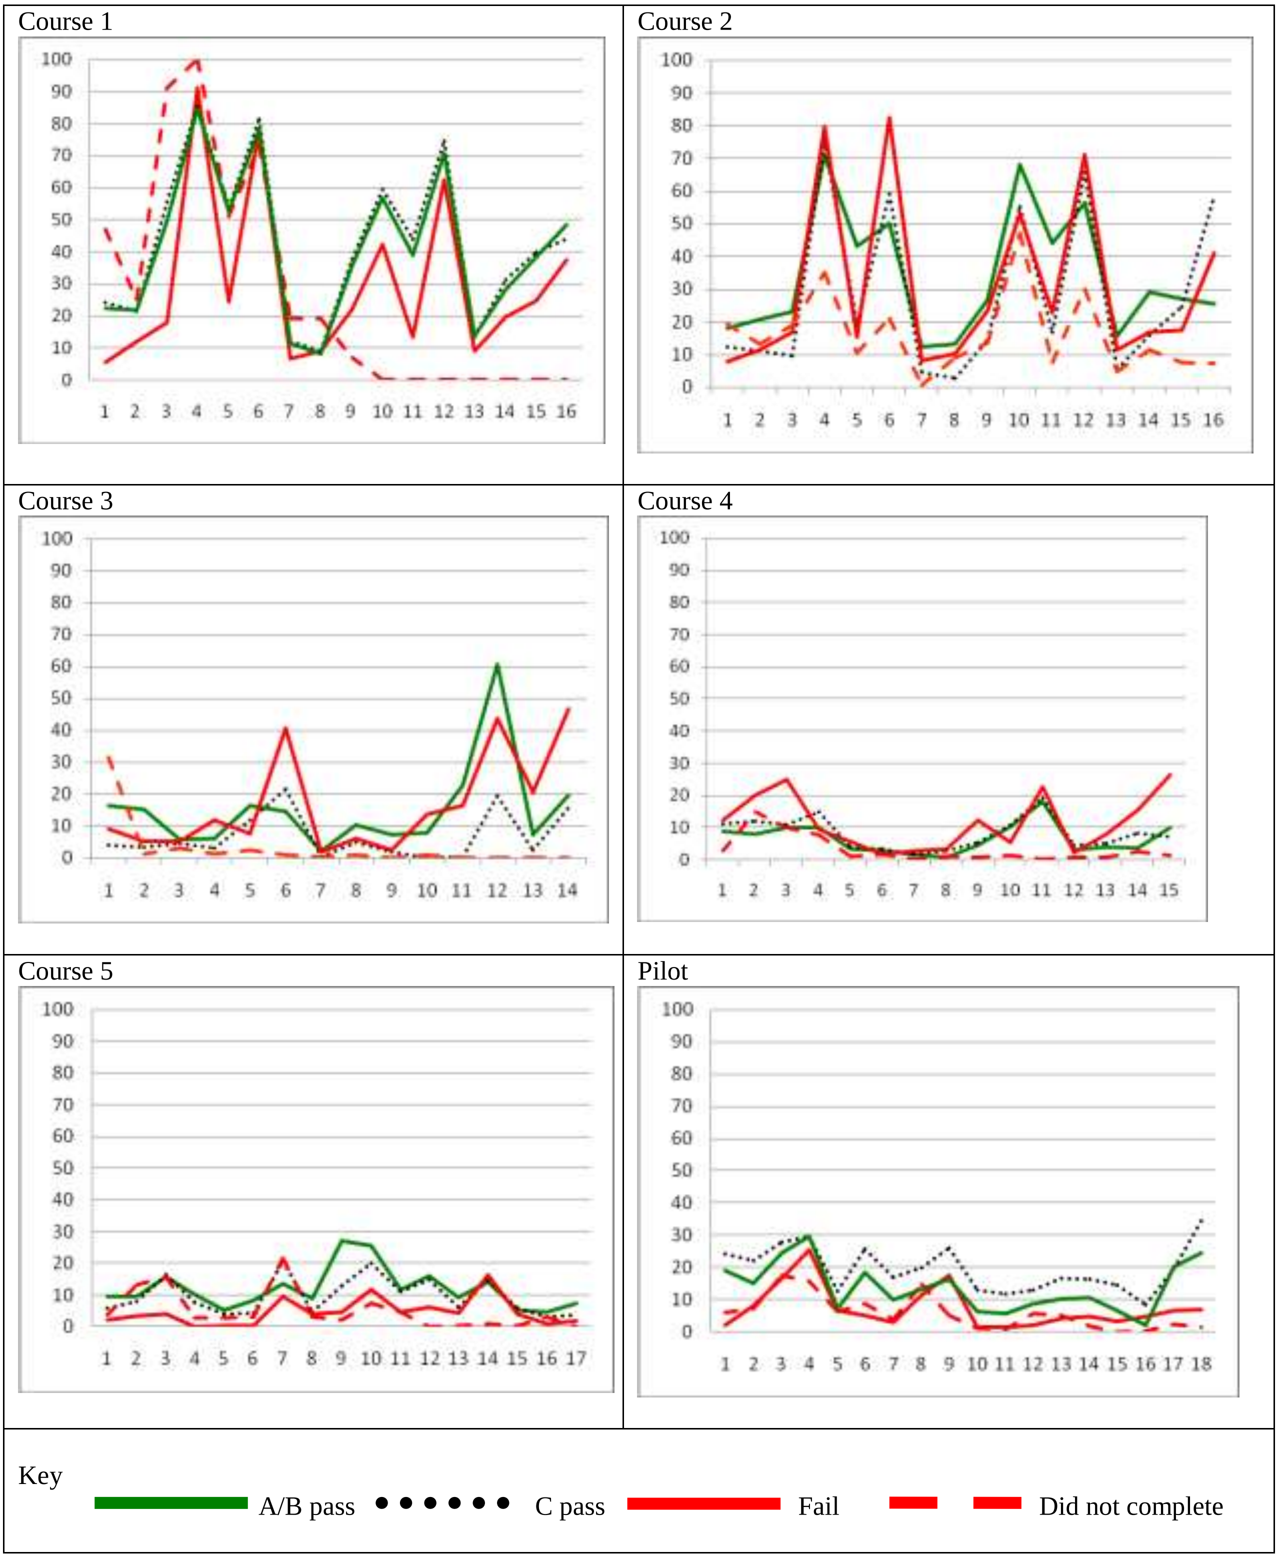

Figure 2: Graphs of students' use of LMS grouped by overall student success

Discussion

Successful students are purposeful and make good of use their learning time. This includes starting at the early stages of the course so they have enough time to learn. This paper has identified a simple approach that identifies students who are slow to start online activity. A significant percentage of this group (see Figure 1) will not pass and would benefit from some reminders to start work.

While there are a variety reasons for failing a course, such as student behaviour or subject choice (Trotter & Roberts, 2006), it is well established in the literature that successful students attend more face-to-face lectures than those who do not complete or fail (Fitzgibbon & Prior, 2003; Gracia & Jenkins 2002). The LMS offers lecturers an easy way to identify students who are may be at risk while there is still time to help the student. Ways to encourage at risk students to engage, or re-engage, include contacting them to remind them about getting started on the course, giving them information about time management and the support that is available including centralised learning support.

Engagement is the key to student success. There are a number of ways that lecturers can help students engage in their studies. Kahu (2011) provides a framework of engagement with three dimensions. These are Affect which is based on enthusiasm and belonging, Cognition based on deep learning and self regulation and Behaviour based on time and effort, interaction and participation. The identification of students who do have not logged in to the LMS in the first week involves using the behavioural dimensions of engagement and then reacting with strategies on the affect dimension to encourage students to become part of the group with the lecturer showing an interest in the student.

Lecturers need to understand how to improve retention and success. They can do this by understanding student engagement and use frameworks that Kahu (2011) and others such as Jeffrey, Milne, Higgins and Suddaby (in press) provide to alter student behaviour, cognition and affective elements of their learning.

DeHub: Examples of some projects and models for future collaboration

Victor Minichiello
University of New England

Rosalind James
DEHub
University of New England

Peter Albion
University of Southern Queensland

Mark Brown
Massey University

Bobby Harreveld
Central Queensland University

Mike Keppell
Charles Sturt University

DEHub was established in 2009 at the University of New England (UNE) and, with the support of an Australian Commonwealth grant, has initiated a number of projects in the field of distance education. It is an academic unit for promoting knowledge transfer about best practice in distance education and supporting national and global collaborations on evidence-based approaches to effectively and efficiently employing new technologies in distance education. CQUniversity (CQU), the University of Southern Queensland (USQ), Charles Sturt University (CSU) and Massey University partner with UNE's DEHub in selected research activities, forming a consortium of Australia and New Zealand's largest and leading distance education providers. The Commonwealth grant supporting a range of projects emerging out of UNE's DeHub is drawing to a close in December 2012.

This presentation will firstly provide an overview of UNE DEHub's networking initiatives and other sector activity, including research conducted or supported by DEHub over the past three years. An update on outcomes from some of the DEHub research projects externally funded by the Council on Australia Latin America Relations (COALAR), the International Council of Distance and Online Education (ICDE) and the Office of Learning and Teaching (OLT) will be highlighted.

Secondly, this presentation also gives an opportunity to disseminate the findings of some of the large DEHub-funded research projects undertaken by partner institutions:

- *In their own words: Experiences of first-time distance learners*. (Massey University & Charles Sturt University)

This Massey University-led project in collaboration with Charles Sturt University was set against the backdrop of significant challenges facing distance education. The research objective was to help enhance services and resources available for distance learners. It undertook an audit of current support services and investigated the experiences of first-time distance learners in their own words through weekly video diaries. The research reports a number of key takeaways and lessons for institutions as well as for distance learners in terms of student success and engagement.

- *Learning leadership in Higher Education – the big and small actions of many people (*Charles Sturt University & Massey University)

This Charles Sturt University-led project in collaboration with Massey University found that learning leadership was enabled by the large and small actions of many people working individually and collectively in relationship to change. In addition, innovation in the case studies were fostered through – delegated leadership, distributive leadership model, faculty scholarship model, networked learning model and diffusion of innovation model.

- *Interacting E-learners: Analysing learner-learner, learner-teacher and learner-content interactions in five online courses in two Australian distance education universities* (Central Queensland University & University of Southern Queensland)

This Central Queensland University-led project crafted and trialled a forward-looking research approach in its use of learning analytics and qualitative methods to harvest and interrogate learning interactions in LMS courses. Five case studies were constructed, and a model for learning interactions produced. It is clear that learning analytics promise data-driven decision-making for the macro-level institutionalised strategic management of human and physical resourcing in universities. Yet it is equally clear that qualitatively rich data collection and analysis contributes significantly to understanding curriculum design and pedagogical practices that stimulate human interaction within virtual environments, corresponds with heightened student engagement with course content. It is the focus on human interaction and less so on content that results in more rounded interactivity and engagement in the course itself.

Finally, the presentation will discuss some of the lessons learnt about how to better foster collaboration in distance education academic activities. These will be shared with the delegates for discussion, with an agenda for further research and capacity development for the field highlighted.

Identifying key actors for technology adoption in higher education: A social network approach

Negin Mirriahi
University of British Columbia

Shane Dawson
University of British Columbia

Debra Hoven
Athabasca University

Higher education institutions are increasingly implementing strategies and practices aimed towards enhancing learning for the future by integrating educational technologies with classroom instruction. Despite the notable affordances these technologies bring to the learning context, there continues to be some resistance within the academy. Senior higher education administrators or leaders are frequently challenged with developing novel strategies to influence technology adoption. Prior studies relating to technology adoption and diffusion have emphasized the importance of collaboration, mentorship, and communities of practice in influencing the level of technology acceptance. Research in social networks has also shown that key actors within a network can assist with the dissemination of information. This case study investigated the relationship between the position of instructors within their departmental social network and their level of technology adoption to begin to identify strategic access points for facilitating technology adoption within higher education.

Keywords: technology adoption, social networks, higher education

Introduction

Educational technology has been readily available to enhance and supplement teaching and learning practice for the past several decades (Conole, 2010). From the drill and practice exercises in the early days of computer-assisted technologies in the 1970s and 1980s to the growth of educational video and audio during the 1990s, instructors have had a suite of learning technologies available to better complement their pedagogical approaches (Salaberry, 2001). Recent developments in web-based communication and mobile technologies, in particular, have further extended and added to the advantages technology integration can bring to education such as increased flexibility of access and student engagement (Chen, Lambert, & Guidry, 2010). In parallel, higher education leaders are now faced with the challenge of responding to the rapidly evolving global education market and learning needs of the contemporary student body and determining ways of extending educational opportunities beyond the traditional classroom (Hagel, Brown, & Davidson, 2010). For instance, the growth of technology mediated learning opportunities through the University of Phoenix and more recently Edx or MITx and coursera has forced the more traditional institutions to rethink their technology approaches and potential student market.

Senior higher education administrators and leaders have focused on technology integration as a way to meet the demands associated with a global education market and competition (Conole, 2010). Despite the strategic leadership and support, there continues to be resistance across many campuses (Roberts, 2008), an issue that senior higher education administrators and leaders are required to address by finding ways that technology can best be diffused and accepted by individual instructors (Abrahams, 2010). Numerous social, cultural, and socio-technical factors can influence an instructor's decision to use a particular technology for their teaching and learning practice. For instance, Mwaura's (2003) study, investigating technology adoption of faculty members who attended a technology workshop, revealed that collaboration and mentorship amongst instructors influenced their future acceptance of a particular technology. Similarly, Oncu, Delialioglu, and Brown's (2008) study of the factors that influence mathematics instructors to adopt technology, discovered that when instructors meet with colleagues who are technically advanced, they begin to relate the potential of learning technologies to their own practice. As Kopcha (2008) posited, instructors who are technologically advanced can act as mentors and advocates of technology by sharing materials and experiences with their peers. By acting as a role model to their peers, these innovators or early adopters of technology can help support and advance the strategic initiative of their institutions (Roberts, 2008).

While adopters of learning technologies can share and promote ideas and support amongst their colleagues, it is critical that their status within the peer network is perceived as a role model or educational leader. Instructors who do influence the teaching strategies of their colleagues are frequently regarded as leaders within their immediate network of instructors (de Lima, 2008). To better facilitate technology adoption, senior higher education administrators can therefore turn to the instructors with technology expertise and leadership or influencing qualities, to raise awareness of the affordances of educational technology and share strategies with their colleagues by establishing communities of practice. While, COPs have now long been in existence and promoted extensively in the professional development and learning and teaching sphere, there remains the complexity of readily identifying those adopters that demonstrate the potential for influencing peers within their social network and assessing the level and sophistication of their technology adoption.

Communities of Practice

A community of practice includes professionals who share a common concern or passion about a subject and who wish to interact with one another to share ideas and enhance their knowledge (Wenger, McDermott, & Synder, 2002). Learning about new concepts or strategies, such as integrating technology with teaching practice, can often occur when instructors come together and form a community of practice that involves both those who are technologically advanced and those who have less experience with technology. According to Lave and Wenger (1991), learning occurs when newcomers to a community of practice move from peripheral participation to full active participation at the core of the community. Hence, those who are at the center of a community of practice are involved in collectively learning and building upon previous knowledge as they continue to develop and refine their practice (Wenger, 1998). Either through self-selection or after being invited by a colleague, members of a community of practice meet to develop and promote best practices or to solve a problem together. While such interactions help foster the sharing of successful teaching practices, instructors also prefer to have such conversations with those who they have known for some time and with whom they feel comfortable (Roxa & Martensson, 2009). Trust between colleagues is critical for meaningful and open conversations to take place without negative judgment (Niesz, 2007), thereby prompting further collaboration and tacit knowledge creation (Hagel et al., 2010). A community of practice of instructors led by those who are technologically advanced and considered trustworthy by their peers can, therefore, help advance the integration of technology with pedagogy. In order, to enhance the integration of technology across an institution, education leaders need to easily identify not only the technology pioneers to lead such communities of practice, but also those who have also established trusting relationships with their colleagues that put them in a position of influence. Assessing individuals' positions in their community of practice may help identify the roles that different community members play in their network and the relationships they have with one another (Schlager & Fusco, 2003).

Social Networks, Emerging Leaders, and Thresholds

Social network analysis can act as an effective approach for identifying potential actors in a network that can facilitate the dissemination of information about new technologies and therefore seed and promote adoption. A social network is comprised of individuals who are tied to one another in a "mesh of connections" (Scott, 1988, p. 109). Such ties or connections represent with whom an individual interacts within a network while an individual's position in that network shows the degree that the individual acts as a vector of information from one side of the network to another. The professional social networks of the instructors therefore tend to include colleagues with whom they have a positive rapport and whose opinions they value highly. Identifying the ties between different members of an organization, such an academic department, can show which instructors emerge as leaders or who perform the role of transferring information across a departmental network. According to De Lima (2008), network centralization measures how much a social network is focused around one particular instructor who can emerge as the leader or hold an influential position. Instructors who are most central in a whole social network tend to have leadership qualities (De Lima, 2008), since others trust and value their opinions and approach them for advice or suggestions (Niesz, 2007).

While an individual's centrality in a whole or partial network indicates their potential importance in the department as a leading figure, their network threshold explains how likely they are to be influenced by the behaviours of others. A network threshold refers to an individual being influenced to change a behavior or decision based on the number of colleagues or connections in a network that behave a certain way (Chen et al., 2009). Individuals who are influenced to change a behavior after many others around them have modified their approach are considered to have a high network threshold while those who are less influenced by others have low network thresholds. Valente (1996) made a connection between individuals' network thresholds and their rate of technology adoption according to Rogers' Diffusion of Innovations Model. Rogers' (1995) model indicates that individuals fall within five stages of technology or innovation adoption: innovators, early adopters, early majority, late majority, and laggards. According to Rogers, the majority of individuals fall within the early or late majority of technology or innovation adoption. As Valente (1996) posits, these early and late majority individuals are influenced to adopt a technology after others have tried it and, therefore, have a high network threshold. Conversely, the innovators, a small proportion of the population, are less influenced by others and are keen to be one of the first to try out a technology. Hence, they have low network thresholds.

Situated in social network theory, this study investigated patterns in social networks to discover any trends between the positions of instructors in their departmental network, their tendency to adopt technology, and how information spreads across the department. Social network theory is most appropriate for studies that explore the relationships and connections between various individuals in an organization or department and the way that information flows among them (Haythornthwaite, 1996). Exploring the relationships between instructors and their network thresholds can determine the “overall web of influence relations that exist within their department” (de Lima, 2008, p. 166), which may help identify those instructors who have this influencing role or potential for it.

Methods

The design of this case study intended to identify the relationship between each instructor’s position in a departmental social network and their technology adoption decisions in order to determine how information flows between participants. A case study approach was used in order to gather and analyze rich and deep descriptions about the professional social networks of each of the participants in the study. In addition, since this study focused on discovering the social networks of instructors in one particular educational institution and who taught in specific academic disciplines, as discussed in the next section, a case study was an ideal methodology for this focus, in this context (Eisenhardt, 1989).

Research Setting & Participants

This study took place in a large higher education institution in North America with approximately 47000 students and 3700 faculty members. Instructors across three academic departments were invited to participate in the study. The three academic departments were situated in the language disciplines and were selected for the high level of educational technology evident in their classroom instruction. These departments had previously played an integral role in developing computer labs to assist students in oral and listening practice. They had actively used the learning management system, Blackboard Vista, for some years, to further extend students’ oral skill practice through improved integration of audio and video resources and activities. This preliminary study aimed to uncover any inconsistent or contradictory trends across the social networks of the three departments. In order to gain the most complete picture possible of the departmental social networks, all language instructors in the three departments (N = 75) were purposively invited to participate. There was an overall response rate of 31%, however, the rate was inconsistent across the departments with Department A having a significantly lower response rate (13%) than Department B (44%) and Department C (41%). The low response rate for Department A was considered when drawing broader conclusions from the study. In addition, some of the participants were course or program coordinators as well as instructors in their respective departments. Their role in the department was taken into consideration during the data analysis, to determine if it affected their overall centrality in the network analyses.

Data Collection

A combination of observational, pre-interview questionnaire, and interview data was collected in this study. In order to identify any behavioural trends across the departmental social networks and to calculate individual network threshold, it was necessary to determine the extent and diversity of technology adoption. Observational data, therefore, was collected from the learning management system course environments of the participants for all their classes taught at the one institution in 2010 and 2011. The data provided insight into the total number of technologies adopted and based within the learning management system by the study participants. In addition, in-person interviews were conducted with each participant in order to identify any further potential technologies that were not associated with the institutional LMS. Semi-structured interviews, rather than surveys were used to collect this data, since interviews provided an opportunity for the participants to elaborate on the reasons for their choice of other technologies, rather than some of the tools available through Blackboard Vista (Cohen, Manion, & Morrison, 2007; Rapley, 2001). The interviews were audio recorded and transcribed and transcriptions were sent to the participants to ensure the accuracy of the content prior to analysis.

In order to build a picture of the departmental social networks, participants were asked to complete pre-interview questionnaires to provide information about the colleagues that they speak to about technology and the frequency of such discussions. Following recommendations by Stork and Richards (1992), a roster of names of their fellow instructors in their academic department was provided to help reduce the likelihood of forgetting or overlooking certain relationships. Furthermore, the pre-interview questionnaire asked instructors to indicate how they perceived their rate of technology adoption according to Rogers' (1995) Diffusion of Innovations Model. The instructors' assessment of their technology adoption assisted with evaluating their network threshold. These data were later analysed in combination with the results of the instructors' network centrality to determine the existence of any statistically significant relationships.

Data Analysis

Observational and interview data were analyzed through content analysis which involved coding and categorizing concepts derived from the written data (Cohen et al., 2007) and developing an aggregation and tally of these (Stake, 1995). Qualitative content analysis software, Atalas.ti, was used to generate codes emerging from the observational notes and the interview transcripts and to create thematic categories. Information gathered from the pre-interview questionnaires concerning with whom the participants spoke regarding technology in their departments was analyzed through social network analysis. A social network analysis and visualization software application, Gephi, was used to determine the position of the participants in their department and develop network diagrams (sociograms) indicating the relationship ties and information flow between individual actors. Figure 1, below, illustrates a social network comprised of eight actors each represented by a single node. The lines between the nodes illustrate connections (relationships) between individuals, while the size of the node represents the number of relationship ties (degrees) they have established in the network structure.

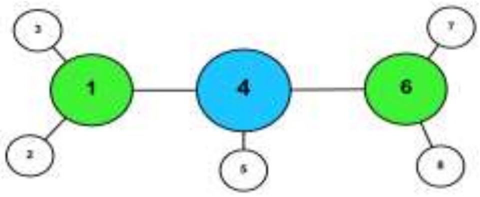

Figure 1: A Network View showing Betweenness Centrality

As seen in Figure 1, the large blue node (number 4) is positioned in the centre of the network. This individual connects with the actors on the left and right side of the network. In other words, information discussed between individuals on one side of a network can flow to those on the other side through this intermediary actor (number 4). According to Freeman (1978), individuals in such positions with high betweenness centrality can influence others by "withholding or distorting information in transition" (p. 221). Hence, analyzing and comparing the location or centrality of instructors in their departmental networks can uncover behavioural patterns prevalent amongst different groups of instructors. As part of the analysis, centrality measures were calculated based on the available network data and then correlated with the participants' total technology adoption, using the Pearson correlation, to determine the extent to which a participant's centrality was proportional to their technology adoption. Statistical software, SPSS, was used to measure the Pearson correlation and identify if the correlation was statistically significant.

Results and Discussion

Prior to investigating the social networks, data was collected through the interviews and observations of the participants' learning management system course environments to identify the extent of technology adoption within each department. This information would later be used during the social network analysis phase to determine patterns and centrality positions of individuals based on their level of technology adoption. The following section reports on the technology use of each participant. For the purpose of this study, technology refers to the specific tools available within the LMS, such as online discussion boards and quizzes, as well as other technologies including blogs, wikis, and digital media that may reside outside of the LMS environment.

Technology Use

Observational data from the learning management environments of the participants was used to indicate the tools each participant had adopted for their classroom instruction. A full mark was given to each type of tool that each participant had chosen to use at least once. Since observational data was limited to the LMS, interviews were required to reveal any other technologies the participants had adopted for their teaching purposes. These other technologies were coded and categorized to determine the total number of technologies that each participant used. Table 1 presents the observational and interview data concerning the total number of technologies adopted by each participant.

Table 1: Total Technology Adoption of Each Participant

Department A				Department B				Department C			
ID	Total	Vista	Other	ID	Total	Vista	Other	ID	Total	Vista	Other
c1A	8	6	2	c1B	4	3	1	i1C	9	7	2
i2A	12	7	5	i2B	6	4	2	i2C	6	2	4
i3A	4	3	1	c3B	5	3	2	i3C	2	1	1
i4A	3	0	3	i4B	4	3	1	i4C	9	6	3
				i5B	7	3	4	i5C	5	2	3
				i6B	8	6	2	c6C	5	4	1
				i13B	6	5	1	c7C	11	7	4
								i8C	5	5	0
								i9C	9	7	2
								i10C	8	6	2
								i11C	4	3	1
								i12C	9	8	1

As presented in Table 1, there is a broad range of technology adoption across each of the departments. Knowing where each participant falls within the technology adoption range will help to reveal any patterns or trends emerging from the social network analysis, the focus of the following section.

Centrality in Social Networks

Data collected on the pre-interview questionnaires was used to determine the partial social network within each academic department. This information, along with the data reported in Table 1 on technology use, was imported into the social network analysis and visualization software, Gephi, and the network centrality of each participant in their respective departments were calculated. Using the Pearson correlation, centrality measures were correlated with all of the participants' technology adoption scores. However, none of the centrality measures had any statistically significant correlation with technology adoption scores ($p > 0.05$). However, while the instructors in Department C were encouraged to develop their own LMS environments, selecting the technologies to adopt for themselves, the instructors in departments A and B tended, for the most part, to teach using the LMS environments created by their language coordinators. The centrality and technology scores for the participants in these two departments, therefore, were correlated together (N=11) as shown in Table 2.

Table 2: Correlation between Technology Adoption and Centrality for Departments A and B

	Closeness Centrality	Betweenness Centrality	Degree Centrality
Pearson Correlation	-.588	.641*	.407
Significance (2-tailed)	.057	.034	.214

***** Indicates statistical significance ($p < 0.05$)

As presented in Table 2, there is a positive significant correlation observed relating the betweenness network centrality with an individual's level of technology adoption. Betweenness centrality refers to the extent to which a participant in a network connects other parts of a network together. Betweenness can be seen to represent characteristics of a 'broker' or 'gatekeeper' of information (Scott, 2007). No significant correlation was observed between technology adoption and neither closeness nor degree centrality. Closeness centrality refers to the distance between the participants in a departmental network while degree centrality refers to the total number of colleagues each participant speaks with about technology.

When delimiting the data into specific departments the correlational trends did not hold true for the third department, Department C. No significant correlation between technology adoption and centrality was observed for the participants in this department (N = 12). Social network analysis of each department separately, as presented in the following section, will illustrate the trends between technology adoption and betweenness centrality and will shed light on different correlational trends cross the departments.

Betweenness Centrality and Technology Adoption

Individuals with a high betweenness centrality are commonly referred to as the “gate keepers” of information due to their linking position in a network. Burt (1992) describes this linking position as bridging a structural hole. In essence, if the individual were absent from the network, a gap in the overall network structure would exist. Hence, individuals demonstrating a high betweenness score tend to fill this void by brokering information across the network. Such individuals can control how information travels to others (Freeman, 1978) and, subsequently, have greater social influence over others in their network (Brass, 1984). To determine the possible influence of participants’ betweenness centrality on technology adoption, the social networks of each department, along with data on the technologies used by the participants, were analyzed. In addition, how the participants perceived themselves on Rogers’ (1995) Diffusion of Innovation scale and, therefore, their network thresholds was considered when determining the potential impact of their conversations. Each department is discussed in turn, followed by discussion of the overall results.

Department A
Figure 2 illustrates the betweenness centrality of participants in the social network of Department A. The nodes represent the four participants as well as the various colleagues the individual instructors mentioned that they talk to about technology. However, as mentioned earlier, several members of this department chose not to participate in the study. These non-participating members are indicated with an asterisk beside their identifying code. The number in brackets next to the participants’ non-identifying code represents the total number of technologies that they have adopted, as previously reported in Table 1.

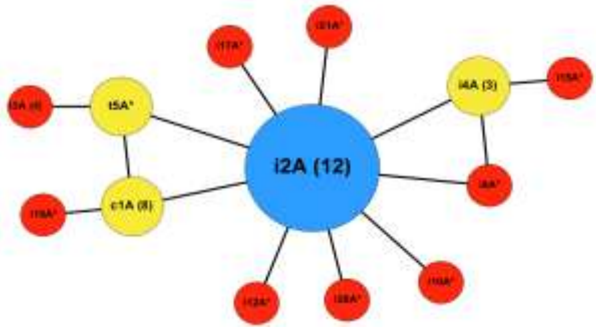

Figure 2: Partial social network of Department A

The lines between each of the nodes in Figure 2 illustrate a connection between each colleague. Since there is a lack of information regarding the types of conversations had by non-participants with those who did participate, there may be more connections than those illustrated above. The size and colour of the nodes visually represent the betweenness centrality of each node or instructor in the network with larger nodes representing higher betweenness centrality. For instance, i2A, represented by the large blue node in the centre of the sociogram has the highest betweenness centrality in this social network. This instructor talks to nine people about technology, three of whom have conversations with one other person. Hence, the conversations that i2A has with those represented by the yellow nodes could potentially affect the conversations between the yellow and red nodes. Moreover, i2A has adopted the most technology in this department, 12 technology applications or tools in total. As presented in Table 2 earlier, as a participant’s technology adoption score rises, their betweenness centrality score also rises. Two colleagues in the department, c1A and i3A, also support this correlation pattern. These two instructors have adopted proportionately less technology and also have a proportionately lower betweenness centrality as illustrated by the large blue node in the centre of Figure 2, compared to the smaller red node at the left. Participant, i4A, the yellow node at the right of the figure, however, represents an exception to the correlation trend, with a similar betweenness centrality to c1A, yet has adopted much less technology.

An analysis of the participants’ technology adoption from the observational and interview data collection and their betweenness centrality helps uncover the potential impact of the conversations between the different colleagues. For instance, i2A who, on the pre-interview questionnaire, indicated being the first to try a technology (i.e. an innovator) actively uses blogs. A colleague, i4A, who speaks with i2A and is an early adopter, and therefore has a higher network threshold than i2A, has also recently started using blogs. The conversations between these two colleagues, therefore, may have influenced i4A to consider using this technology. Similarly, i2A uses online discussion forums and speaks directly with c1A, and also uses discussion forums. Since c1A is in the early majority of technology adoption and thus has a much lower network threshold than i2A, the conversation between these two instructors may have influenced c1A to use online discussion forums. However, since c1A also has conversations with the educational technologist in the department, t5A, this instructor may have heard about the online discussion forums from both t5A and i2A.

Department B

Figure 3 illustrates the social network for Department B and the betweenness centrality of the participants. In this figure, the large blue node, i5B, represents the instructor who has the highest betweenness centrality in the department since this instructor connects the left side of the network with the rest of the nodes. This instructor has conversations with i13B, who in turn has conversation with three other colleagues in the department who, based on the data available, do not have connections with anyone else in the department. Hence, i5B seems to play the intermediary role of helping information flow between the left and right sides of the network.

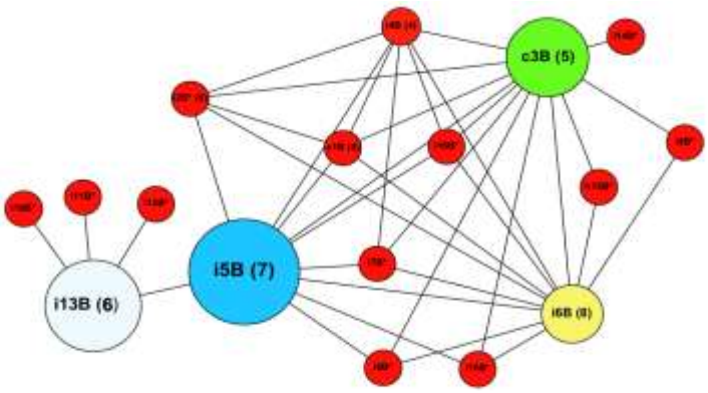

Figure 3: Partial social network of Department B

According to the interview and observation data, i5B is not only a high technology adopter in the department, but specifically uses digital media, technology that i13B also includes in teaching and learning. Furthermore, since i5B is an innovator and i13B falls within the early majority and hence, has a higher network threshold, the conversations between these two participants may have influenced i13B to explore digital media. Likewise, c3B and i6B also use digital media and a variety of other technologies that i5B has also adopted. Since instructors, c3B and i6B consider themselves to be early majority and early adopters respectively, their network thresholds are higher than that of i5B. Hence, conversations with i5B, and potentially with others, may have influenced their adoption of digital media. With respect to the correlation of technology adoption and betweenness centrality presented in Table 2, for the most part, participants in Department B, such as i5B, i13B, and c3B, who have adopted more technologies than others, also have greater betweenness centrality. Additionally, c3B is also a coordinator in the department, which may explain why this participant is more central than others who have adopted greater technology, such as i6B. However, i6B, represented by the yellow node at the far right of Figure 3, has adopted the most technology in the department, yet has lower betweenness centrality than i5B and i13B. This is due to i6B not being in an intermediary position to connect colleagues from one side of a network to another nor to facilitate the spread of information.

Department C

Figure 4, below, illustrates the betweenness centrality in Department C, which, as mentioned earlier, does not manifest the same trends as the other two departments. As illustrated in this Figure, the large blue node represents the participant with the largest betweenness centrality, c6C, who also has adopted less technology than others in the network (5 in total). The large white node represents the participant with the second highest betweenness centrality, c7C. However, unlike c6C, this participant has adopted the most technology in the department. These two participants are also the language coordinators in the department and therefore may have higher betweenness centrality than others, based on their responsibilities in the department. As noted earlier, the language coordinators in this department encourage the instructors to design and develop their own LMS environments. Therefore, their role in their department may explain their high betweenness centrality since they facilitate the spread of information across their department. However, the two green nodes represent the instructors with the next highest betweenness centrality scores, i10C and i11C, who do not have coordination responsibilities. One instructor, i10C, is a high technology adopter while the other, i11C, is a low technology adopter. Thus, a pattern of correlation between technology adoption and betweenness centrality does not emerge in this department.

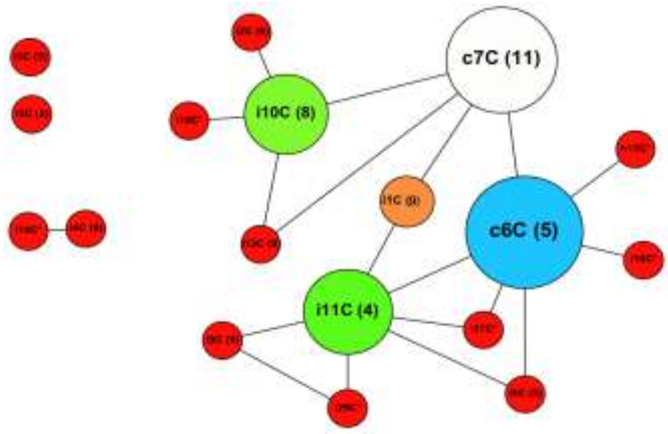

Figure 4: The partial social network of Department C

Investigating the types of technologies that the participants have chosen to adopt, however, shows that conversations amongst the participants may have had some influence on technology adoption. For instance, c7C is an early adopter and is a heavy user of PowerPoint Presentations and the online discussion board, which are both technologies that i10C and i12C also use. Since i10C is also an early adopter, the conversations between this instructor and c7C may have influenced both of them to use the technologies. The other instructor, i12C, is in the early majority group and, therefore, has a higher network threshold than the other two. Hence, conversations with i10C and c7C may have influenced i12C to consider using those technologies. In addition, i2C, represented by a small red node at the top of Figure 4, is also an early adopter and uses online discussions and digital media. This technology is also adopted by c7C. The intermediary position of i10C in the network, therefore, may facilitate the flow of information concerning online discussions and digital media between i2C and c7C. Likewise, i11C is in an intermediary position between i9C and i1C, who are the only participants who use the same vocabulary tool. Since i1C is an early adopter and i9C is in the early majority with a slightly higher network threshold, information about the vocabulary tool may have flowed from i1C to i9C through i11C.

Emerging Patterns

The analyses discussed earlier in this paper highlight two patterns. While departments A and B showed a positive correlation between technology adoption and betweenness centrality more than half of the time, a similarly significant relationship was not observed in Department C. However, analysis of the combined data such as with whom the participants spoke, which technologies they adopted and their network thresholds, showed that certain participants had an intermediary role, assisting with the flow of information across their departmental network and subsequently influencing their colleagues to consider certain technologies. This resonates with Burt's (1992) notion that structural holes create a gap in the flow of information between members of a network and a third person is needed to be an intermediary to fill this gap. Individuals near these bridges, therefore, have better opportunity to access new information that can lead to improving their social capital and influencing their decisions (Lin, 1999). Furthermore, there are parallels between this study and previous studies on collaboration and communication (Davis, 2005; Mwaura, 2003; Valente, 1996) in that there was also a trend in this study for conversations between those with lower network thresholds, such as the innovators, to have a potential influence on the technology adoption decisions of the participants with higher network thresholds, such as the early adopters or early majority. These findings also support the results of social network studies that have determined that communication amongst instructors can influence their decisions to use a particular teaching approach (Roxa & Martensson, 2009). The role of the participants with high betweenness centrality and the potential flow of information and technology adoption across the network also justify social network theory as a theoretical paradigm to explain technology adoption decisions.

The trend that emerged in two of the departments in this study begins to show that the technologically advanced instructors may also have positions of influence in their department networks since they tend to have an intermediary role that assists with the spread of information valuable to their colleagues and thus enhances overall social capital (Lin, 1999). It is likely that such spread of information and enhanced social capital is the result of key actors in the department networks developing trusting relationships with their colleagues (Niesz, 2007).This is of particular importance for senior higher education administrators and leaders since the success or failure of technology acceptance depends, to some extent, on their ability to identify the trail-blazing technology adopters who can help implement change and transform their institutions (Hagel et al., 2010). After these adopters have been identified, the senior administration can enlist these key instructors to help promote the integration of educational technology by leading technology-related communities of practice (Kopcha, 2010; Roberts, 2008) or spreading information about new technologies through informal conversations with colleagues in their departments. One way for the senior administration to discover the influential instructors would be to identify the instructors who have adopted a high number of technologies as suggested by the trend revealed in this study. Since senior higher education administrators and leaders do not readily have access to information concerning which instructors at their institution have adopted the most technology, technology support units can play a critical role in obtaining such data and providing reports to senior administration. Information concerning the types and number of technologies that instructors use can be extracted from various technical systems, such as the learning management system, assisting educational institutions with implementing technology diffusion strategies (Dawson, McWilliam, & Tan, 2008). By leveraging the data supplied by the technology support units, senior higher education administrators can recruit the high technology-adopting instructors to help increase technology acceptance across their institution. Such technology diffusion strategies can assist educational institutions to better meet the demands of the global education market (Conole, 2010) by increasing access to online learning opportunities and enhancing student engagement. While this study discovered a potential correlation between network position and technology adoption, which can help identify key instructors to assist with technology diffusion, future studies, as discussed in the following section, are required to further determine its significance and applicability to the broader community.

Summary and Future Directions

This study investigated the social networks of academic departments and discovered a potential correlation between technology adoption and instructors' positions in their departmental networks. As reported, social network analysis of two departments showed that instructors who have adopted a greater number of technologies tend to be in an intermediary position in their department network and, hence, assist with the spreading of information across a departmental social network. Furthermore, this study revealed a tendency for instructors with greater betweenness centrality to have a lower network threshold than others, and therefore, the potential to influence adoption decisions of their colleagues demonstrating a higher network threshold. Both the instructors' particular intermediary role in their departmental network together with their ability to influence peers with higher network thresholds may be a result of the trust they have gained from others in their network. Future studies with a greater number and diversity of participants across disciplines are required to substantiate or refute the trends observed here. Further research can also help advance understanding of the factors influencing technology adoption amongst instructors, in particular the role that trust plays in certain instructors being in a position of influence in their professional social networks. In addition, since the social network analysis in this study was focused on ties between colleagues in academic departments, future studies can specifically investigate instructors' online social networks, such as Twitter and LinkedIn, to determine how they can be leveraged for enhancing technology adoption. Identification and recognition of factors influencing instructors' technology adoption decisions can assist with the provision of the resources and support necessary for higher education leaders to develop strategies for the integration of appropriate technologies within current teaching and learning practices. This study is merely a commencement point for discussion on the insights that social network analyses can bring forward, to aid and inform strategic initiatives designed to promote the use of learning technologies in the education context.

Benchmarking Open Educational Practices in Higher Education

Angela Murphy
Australian Digital Futures Institute
University of Southern Queensland

Open Educational Resources are widely discussed in higher education circles and open education practices are being upheld as the second generation of OERs that have the potential to make education freely available to all students. The OERu is a collaborative initiative between 12 institutions globally that is intending to offer courses free of charge to students using only OERs and open practices. This poster presents preliminary results from a research study conducted with 110 representatives of higher education institutions around the world, of which 12 were official; members of the OERu. The study was aimed at identifying the extent to which higher education institutions are currently implementing open policies and practices as well as explore the challenges faced by institutions when considering implementing open initiatives. Results from the study indicate that although higher education institutions are aware of and interested in open education resources and initiatives such as the OERu, there are a number of challenges that need to be overcome before these initiatives are sustainable and more widely adopted.

Keywords: Open Educational Resources, OERs, Open Educational Practices, Open Educational Resource University (Oeru)

Introduction

At first glance the Open Educational Resources (OERs) movement and increasingly open educational practices seem set to change the future landscape of higher education. The successful implementation of open education practices, which includes OERs, has the potential to make education opportunities freely available to all students, particularly those previously excluded from formal learning (Mackintosh, 2012). Interest in OERs has increased exponentially as a topic of research and debate since the term was first adopted in 2001 when MIT became the first institution committed to making all of its course materials freely available through its OpenCourseWare (OCW) program (Baker, 2008). Since then, over 270 organisations and educational institutions internationally have adopted the "opencourseware" concept and have incorporated the principles underlying openness into their policies and practices (http://ocwconsortium.org).

Increased emphasis on the development of OERs and avenues for open learning represent a growing critique of traditional, institutionalised systems of education. According to Taylor (2007), existing education platforms are unable to meet the growing demand for higher education within the limited increases in resources. While to this point in time most of the focus has been on the creation and development of OERs, there are now a number of initiatives to create formal credentialing of studies undertaken using OERs which will result in recognised qualifications. These initiatives and other open educational practices are emerging as the second phase of the OER movement (Ehlers, 2011), which will challenge institutions to consider new delivery models, curriculum development, pedagogy and sustainable business.

The OER university (OERu) (Taylor, 2007) is one of these initiatives that signifies a step towards developing a feasible framework for integrating available OERs into assessable online courses. The OERu is based on a conceptual framework that provides a structure for enabling free learning opportunities for students who lack the means to access traditional higher education. The ultimate outcome of the OER university collaboration is to ensure that OER learners can achieve credible qualifications from formally accredited participating institutions (Taylor, 2007).

A number of studies (e.g. Ehlers, 2011; Bossu, Bull, & Brown, 2012) have pointed out that the potential of the OER movement to transform education practices has not been realised, largely because of a lack of focus on the policies and practices required to promote the concept of openness within higher education institutions. Despite research conducted to date, however, there is still limited evidence on how to successfully integrate OERs and principles of open education into the policies of educational institutions and limited research has been conducted on the resulting impact of open educational projects on institutional policy and practice. The aim of this project is to identify the extent to which higher education institutions around the world are currently implementing open education policies and practices that support the successful implementation of formal assessment and accreditation services for informal learning based solely on open educational resources.

Research Method

An OERu compatibility survey was developed as a collaborative initiative between the author, Gabi Witthaus from the Beyond Distance Research Alliance (University of Leicester) and Wayne Mackintosh from the OERu Foundation. Many of the questions were derived from a series of interviews carried out with individuals from institutions participating in the OER university (OERu) network as a component of the Toucans project (Witthause, 2012) and input was provided into the survey questions by OERu network members. The survey was programmed and hosted using an online survey tool and a link to the survey was disseminated using social media such as Twitter and Facebook and through newsletters and discussion forums. On completion of the survey all respondents received a PDF of their responses which they will be able to use as a benchmarking tool to map the compatibility of their organisations with the OERu concept against the final results.

A total of 110 representatives of higher education institutions around the world completed the survey. Participants included 12 higher education institutions that are officially members of the OERu network (also known as the OERTen partner institutions) and 98 that are not partner institutions. The final outcome of the study will be a compatibility indicator for the OERu concept based a comparison of the findings from the two groups. Institutions from across the world participated in the study with the majority originating from the United Kingdom (40%), North (17%) and South America (15%), and Australia / New Zealand (9%).

Discussion of Results

The results of the study indicate that the majority of participants in the study (88%) were familiar with Open Educational Resources prior to participating in the study and 67% were familiar with the OERu (option 4 or 5 on a five point scale from not very knowledgeable to very knowledgeable). One of the most predominant themes was the high awareness of OERs and the OERu in comparison to the low involvement of institutions in open practices that support the development of OERs. Three in ten (29%) participants represented institutions that were published OERs, yet only 24% were using OERs developed by other institutions or organisations. Only 24% were involved in the collaborative development of OERs with people in other institutions and as few as 8% were presently providing courses based solely on OERs (option 4 or 5).

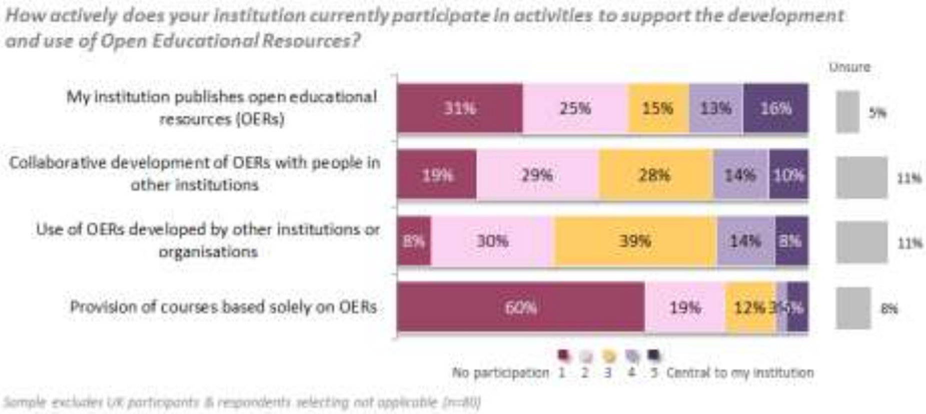

Figure 1: Institutional participation in OER development activities

Participants were requested to rate the factors that hinder the successful implementation of OER based courses on a five points scale from not at all (1) to a large extent (5). The greatest barriers to participation in the development of OER based courses (option 4 or 5) were leadership support, cost and time. Between over 60% participants considered the lack of availability of volunteers (66%), lack of support at the senior leadership level (61%), cost of redeveloping courses (66%), lack of availability of committed staff members (67%) and lack of integration with current workflows and obstacles (67%) to have a large impact on the successful implementation of open education courses and processes.

It appears that although the concept of courses conducted using only open educational resources is a topic of interest and discussion in higher education, it is a concept that is still in its infancy. There remain a number of challenges at an institutional level, particularly with regard to support from senior management that will need to be overcome before wider adoption is possible.

Development of a framework for evaluating the impact and sustainability of mobile learning initiatives in higher education

Angela Murphy
Australian Digital Futures Institute
University of Southern Queensland

Helen Farley
Australian Digital Futures Institute
University of Southern Queensland

The field of mobile learning is becoming more capable of supporting high quality learning experiences and students are increasingly demanding greater mobility and flexibility. As a result, Higher Education Institutions are increasingly considering the implementation of institutional m-learning strategies. We present the aims and approach of a three year project to be conducted by the Australian Digital Futures Institute to develop an m-learning evaluation framework (MLEF) that will aid the selection and justification of m-learning initiatives. The framework will be encapsulated in an easy to use online evaluation toolkit which will consist of: a standardised evaluation framework, resources and guidelines; an m-learning maturity model; a database of m-learning exemplars; and an interactive mobile user model. The project is a collaborative initiative between USQ, ANU and UniSA and is supported through the Australian Government's Collaborative Research Networks (CRN) program. Participatory monitoring and evaluation (PM&E) methods will be used to develop outputs and deliverables.

Keywords: Mobile learning, m-learning, mobile learning, evaluation frameworks, sustainability

Background: Evaluating Mobile Learning Initiatives in Higher Education

As mobile technologies have evolved and become more capable of supporting learning experiences in both blended and stand-alone contexts, the field of m-learning has emerged as a new learning paradigm and become a focus of research and development activities (Kukulska-Hulme et al., 2011; Engel et al., 2011). Over the past ten years, a number of pilot or experimental research studies have been conducted across sectors to investigate the impact of mobile technologies on learning and teaching (e.g. Elias, 2011; Biggs & Justice, 2011; Wong, 2012). One of the most consistent conclusions of these studies is that there are still a number of barriers that influence the adoption of m-learning initiatives in education, both at an institutional and at a user level. HE institutions are cautious about investing extensively in mobile technologies because of the rate of emergence of new models and the speed with which devices become obsolete. Few HE institutions have therefore implemented well-financed and highly visible m-learning initiatives that are operationalized within policy and practice.

A report conducted for the JISC e-Learning programme in late 2010 indicated that the most prominent issue in the field of m-learning is the lack of full scale evaluations of mobile technology in Higher Education (Wishart & Green, 2010) and the absence of a stable platform from which to effectively research the role, drivers and impact of mobility on learning (Park, 2011). A significant challenge facing most HE institutions is identifying strategic and operational priorities for investment in m-learning capabilities within a rapidly changing field, while maximising the educational outcomes for students and minimising institutional costs. This poster describes a three year project to be undertaken by the Australian Digital Futures Institute that will address this gap by developing an effective assessment mechanism that can be used to evaluate whether m-learning initiatives are successful, scalable and replicable.

Project Aims and Approach

The aim of this project is to develop a framework for mobile learning or m-learning that will enable Higher Education (HE) institutions, learning designers and educators to evaluate the impact and sustainability of m-learning initiatives within a range of learning contexts. The m-learning evaluation framework (MLEF) will be developed to facilitate and support HE institutions in the assessment, development and embedding of m-learning policies and/or practices to enhance the learning experiences of students and support long-term planning for improved learner and institutional outcomes. The framework will be independent of specific technologies and therefore will remain relevant despite the emergence of new devices.

The focus of the project on building an evaluation model that is sufficiently flexible to accommodate the current and future needs of students and educators for m-learning initiatives. For this reason an iterative approach will be used to ensure that each commencing stage is built from the insights obtained in the previous stage and allow the inclusion of new insights and innovations in the field as the research project matures. Participatory monitoring and evaluation (PM&E) methods will be used as the project involves the development of artefacts, such as the toolkit, which are aimed at being responsive and relevant to the needs of the education community.

The project will be undertaken as a three-year collaborative initiative between three participant universities; USQ, ANU and UniSA. Three levels within higher education will be examined as recommended by Quinton and colleagues (2010): pedagogical, technical and organisational. The following groups that represent each layer will be consulted during this stage to identify the needs, expectations and challenges of each level when considering the implementation of m-learning initiatives:

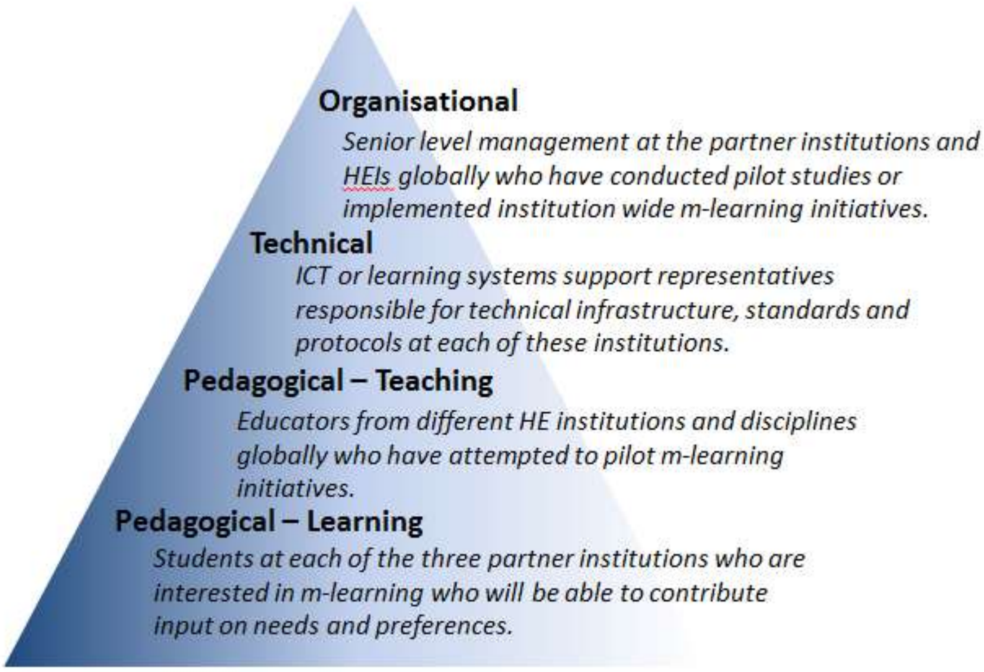

Figure 1: Groups to be consulted in the development of the MLEF

Outputs and Deliverables

The primary deliverable of the study will be an online m-learning evaluation toolkit that will provide a set of procedures, guiding principles, methods and examples to be used by HE institutions and educators when evaluating m-learning initiatives for inclusion in policy and practice. The m-learning evaluation toolkit will consist of the following components:

- *A conceptual evaluation framework and evaluation resources* consisting of a set of evaluation criteria and standardised assessment instruments as well as checklists, guidelines and step-by-step tutorials for the evaluation of m-learning initiatives within various contexts;
- *A m-learning maturity model* that will enable HE institutions to assess the maturity of their m-learning capabilities and provide best practice recommendations for policy development and institution-wide co-ordination and communication;
- *A database of m-learning exemplars* in the form of case studies and resources that have been demonstrated to contribute to high quality learning experiences; and
- *A mobile user model* consisting of normative data compiled from the research component of the study that provides insight into the context, background, needs and learning styles of students and enables benchmarking of the role, drivers and impact of m-learning within various learning contexts and environments.

The project will result in a rigorous and transferable conceptual framework for m-learning evaluation that will enable higher education institutions to consider the impact of new m-learning strategies within the context of current capacities and the future impact on the quality of the student learning experience.

Acknowledgement

This project is supported through the Australian Government's Collaborative Research Networks (CRN) program.

Following the Sun: Sustainable conferencing in a climate of change

Angela Murphy
Australian Digital Futures Institute
University of Southern Queensland

Shirley Reushle
Australian Digital Futures Institute
University of Southern Queensland

This paper reports on a new initiative in online conferencing that has resulted from the collaboration between three tertiary institutions on three continents and across three time zones. The paper describes the role of the Follow the Sun Online Learning Festival in revitalising professional online learning and networking events in a similar manner to the way in which e-learning revitalised tertiary education. The paper also discusses the evaluation of online conferences and introduces the new learning methodology as an alternative method for evaluating online conferences. The methodology used to evaluate the Follow the Sun Learning Festival is discussed and some preliminary findings are shared. Initial results suggest that online learning events have the potential to engage and connect professional peers and facilitators across traditional geographical boundaries. The potential for the Follow the Sun conference to result in new learning is however still unresolved.

Keywords: online conferencing, collaboration, evaluation, new learning

Introduction

Computers and the internet have long been attributed with revolutionising and revitalising teaching and learning within the tertiary education sector (Selwyn, 2007). Advances in internet based communication technologies have been noted particularly for improving distance education. Furthermore, online instruction enables the interaction and exchange of information between learners based on physical campuses or in distant or disadvantaged locations (Johnson, Aragon & Shaik, 2000) and has as a result been attributed with improving access to educational opportunities and promoting interactivity and collaboration between learners.

Conferences and training events have for many years been perceived as a primary tool for improving professional knowledge and networking, resulting in improved competence and performance in practice (Anderson & Anderson, 2012). With the increasing economic and environmental costs associated with long-distance travel, many organisations have implemented environmental policies to limit meetings that involve travel and professionals are required to be more restrained with the number and range of professional development opportunities they engage in. Anderson and Anderson (2009) identified that although many organisations have overcome these restrictions by using online communication technologies for meetings, few organisations have committed to delivering traditional face-to-face conferences or training events wholly online.

Online professional learning conferences or events offer the potential to combine the e-learning models developed for online tertiary education with the needs of participants prevented from attending conferences as a result of time or travel restrictions. Web conferencing software enables synchronous internet-based collaboration and communication and is therefore ideally suited to enabling the interaction between facilitators and participants so valued in traditional face-to-face training or conference proceedings. Online conferences by themselves are not a radically new concept, but as online conferencing technologies continue to become more inexpensive, ubiquitous and advanced, there is greater potential to leverage these resources to enhance the future of learning for students and professionals. The challenge for learning organisations that are preparing to move towards hosting or facilitating online conferences is to develop events that will attract and sustain the engagement of online audiences, rather than simply repurposing the processes and formats followed in the past.

This paper reports on an attempt to offer an online conference synchronously in a new and innovative manner. The format of the conference was intended to capture the attention of a global, multi-disciplinary audience, facilitate the development of digital communities within disciplines and present new ideas for using digital technologies for learning within these disciplines. The conference was hosted over a period of 48 hours in three continents and time zones and connected more than 300 participants in over 40 countries. A comprehensive evaluation of the conference was conducted to determine the extent to which participation in the event resulted in new learning and the sustained effect of these learning's over time. The aim of the evaluation was also to determine whether the format utilised was suitable for engaging and sustaining the attention of attendees participating at their desks from personal computers across time zones and was able to meet their learning expectations.

Follow the Sun Online Learning Futures Festival

The University of Southern Queensland is committed to excellence in applied research as well as the utilisation of innovative technologies for the future. A significant event supporting this research strategy has been the conduct of a non-stop, 48-hour online global conference, the Follow the Sun Online Learning Futures Festival, now in its second year of offer in this format.

In 2012, the event was organised by the Australian Digital Futures Institute at the University of Southern Queensland (USQ, Australia), Beyond Distance Research Alliance at the University of Leicester (UK) and Athabasca University (Canada). The festival was held entirely online, delivered through the web conferencing system, Blackboard Collaborate. It ran non-stop for 48 hours, held over six shifts of eight hours each, with consecutive handovers between Australia (USQ), United Kingdom (Leicester) and Canada (Athabasca). Australian Digital Futures Institute and Beyond Distance Research collaborated in 2011 to host the conference using Adobe Connect. The 2011 conference focused on educational technology, whereas the aim of the conference in 2012 was to examine knowledge development and exchange across disciplines.

There were 266 registrations for the conference in 2011 but over 750 registered across 35 countries in 2012 (see Figure 1 for a graphical representation of the countries of all registered delegates). The festival was free to all participants and recordings of all sessions were made available after the event, supporting the concept of open educational resources. The decision to make the event free in 2012 was consistent with the University's mission to enable broad participation in higher education and to make a significant contribution to research and community development.

Figure 1: 'Where are you?' Map created of delegates who registered for Follow the Sun 2012

The festival featured keynote speakers from across the world representing a mix of disciplines including Engineering, Computer Science, Sports Psychology, European Politics, Nursing, Midwifery and Ethnomusicology. The primary goal of the conference was to move beyond the theme of educational technology and bring together university staff and students within these disciplines from across the globe to share new ideas, exchange information and explore knowledge development. The festival was split into four-hour sessions containing presentations, keynotes, interviews and panel discussions, with each session focusing on the possible digital futures of a particular discipline.

The second goal of the conference was to present an online learning event in an innovative and sustainable manner. The event was designed to be flexible and accommodate time pressures experienced by participants by allowing delegates to log in and out as they pleased and to have access to session recordings. As the registration was free, the conference was designed to be openly accessible, regardless of geographic location or economic restrictions. Lastly the conference drew on the potential offered by technologies such as Blackboard Collaborate to enhance the learner experience and facilitate collaboration through the use of features such as two-way audio, multi-point video, interactive whiteboard, application and desktop sharing, rich media, breakout rooms, and session recording. The conference supported the university's mission of offering quality professional education opportunities that are accessible, flexible and borderless.

Dickinson (1992) stresses the importance of finding new ways of communicating and working together "to confront the problems that threaten the lives of human beings, countries, even the planet itself". Events such as the online Learning Festival can be energy-efficient and sustainable. These events contribute to a reduction of an institution's carbon footprint by being low cost, no travel events that allow participants to attend at their convenience. The conference was therefore also aligned with USQ's Sustainability Pledge, a list of objectives put in place to ensure the University is 'carbon neutral' by 2020.

Evaluation of Online Conferences

Anderson and Anderson (2012) maintain that the evaluation of the effectiveness of professional conferences in achieving improved learning and performance is greatly lacking and focus mostly on the immediate reaction or satisfaction of participants. New learning (NL) is primarily a qualitative methodology proposed by Chapman Wiessner, Storberg-Walker, and Hatcher (2007) as an alternative way of evaluating conferences. Users of this method focus on asking participants to provide information on new learning they have experienced or new questions that have occurred to them as a result of the conference. The question is a reflective question that is intended to prompt participants to provide deeper information on their perceptions and experiences (Chapman et al., 2007) and is ideally suited to professional conferences where new learning is an intended outcome. Making the data collected available to stakeholders is considered to be an essential component, as this enables participants to reflect on divergent perspectives and experiences of conference attendees.

Few studies have been reported using the new learning approach to evaluate conference attendance and no studies, to the authors' knowledge, have been reporting using similar methodologies to evaluate the effectiveness of online learning events. The evaluation approach used for the Follow the Sun Online Learning Festival in 2012 was developed according to the key principles of the new learning approach but was modified to be more manageable within the fast paced online festival environment. The purpose of conducting an evaluation was to not only provide information on the value of the event at its conclusion but to provide insights into the long-term impact of new learning's and information gained.

Evaluating the Follow the Sun Online Learning Festival

The aim of the evaluation of the Follow the Sun Online Learning Festival was to enable a comprehensive and multifaceted analysis of the experiences and perceptions of participants. The evaluation was developed to obtain insight into not only the satisfaction of participants and reactions to the conference but also to capture the benefits and limitations of the event as experienced by participants and identify whether any new learning occurred as a result of participation.

Due to the fast paced nature of the conference and the dispersed geographical location and time zones of participants, it was not possible to fully integrate the evaluation into the conference proceedings as participants would have little time to reflect on learning's and provide detailed responses. As a result, it was decided to use a summative online survey as the primary evaluation instrument. The evaluation was further supported by short evaluation questions after each session posted using Backboard's survey features and the information provided by participants was immediately available to facilitators. These results are not presented in this paper.

Methodology

An online survey evaluation questionnaire was distributed at the end of the conference to all participants who registered for the Learning Festival event. Participants were requested to complete the survey regardless of whether they attended the event or not. A number of directed questions were included that would allow the research team to identify reasons for registering but not actually participating in the conference. This enabled the identification of preferences for formats that may attract attendance and make future online events more accessible and convenient.

The survey consisted of a range of closed and open ended questions that sought demographic and background information, conference participation information including access trends and frequency, familiarity and usage of social media, feedback on experiences and preferences for future online learning events. None of the survey questions were compulsory so that respondents did not need to answer questions they were not comfortable with. As a result some of the samples sizes for questions may differ.

The section that focused on participant experiences moved beyond simply indicating satisfaction with events and resources. Questions were targeted at finding out detailed information on the benefits and limitations of the conference to participants during the conference as well as the impact of the conference on personal learning and potential future practice.

To identify the extent to which any new learning obtained during the conference had a long term impact on individuals and organizations, respondents could opt in to receive reminders about the new learnings and intended actions they identified in future surveys to determine whether they were able to implement them. These reminders were sent out with detailed feedback on the responses to the evaluation surveys at 3 months, 6 months and 1 year after the event. As the evaluation is in the final stages of analysis, the data has not been fully analysed and only preliminary findings are reported in this paper.

Findings and Discussion

A total of 192 completed the survey of which 115 participated in the conference and 77 did not. The majority of respondents described their role as either an academic (n=58, 33%) or an educational designer (n=44, 25%) with 17% describing themselves as professional staff (n=29), 10% as researchers (n=17) and 8% as students (n=14) or other (n=12, 7%). Females formed the majority of the sample with 66% (n=108) participating in the research and only 34% males (n=56). Respondents were from a range of age groups with the majority between 50 and 59 (n=57, 35%) and 40 to 49 (n=49, 30%). Ten percent (n=17) were over the age of 60 and 25% under the age of 30 (41).

Learning festival participation trends

The festival reached a dispersed audience with only 27% from the three partner universities that hosted the event and the remaining 73% from other organisations. Approximately one in three (28%) respondents attended the previous Follow the Sun Festival in 2011 which suggests that the event is attracting a larger and more diverse range of participants year on year.

Respondents were requested to provide some information on participation trends to assist in identifying reasons for registering but not attending the conference or for only attending a few sessions. Although the goal of the conference was to move beyond discussions about learning technologies and result in the development of digital communities within disciplines, the primary reason why participants were attracted to the Online Learning Festival was because of a particular interest in learning technologies (44%). Very few were attracted to the event as a direct result of the relevance of the content to their discipline (18%) (Table 1).

The majority of respondents indicated that the primary reason for not attending more sessions or for not attending at all was because they were unable to take more time away from work (52%) or as a result of previous commitments (37%), with only a small percentage not attending as a result of lack of interest (10%) or technical difficulties (11%) (Table 2). This suggests that the time available to professionals for participation in digital communities and online learning is limited and should be taken into account when designing online learning events to maximize participation and value.

Table 1: Reasons for interest in Online Learning Festival

What is the primary reason why you were interested in attending the Follow the Sun Learning Festival? (Select one)	Total	Participants who attended	Participants who did not attend
Particular interest in learning technologies	44%	37%	55%
General interest in the topics presented	19%	20%	16%
The content is directly related to my discipline	15%	17%	12%
Relationship with one of the participating host organization	11%	14%	5%
Opportunity to network	5%	3%	7%
Interest in a specific speaker	2%	2%	1%
Interest in a specific topic	2%	2%	1%
Other	4%	6%	1%

Table 2: Reasons for not attending more sessions

What were the primary reasons why you did not attend more sessions? (Select all that apply)	Total	Participants who attended	Participants who did not attended
I was unable to take time away from work to attend further sessions	51%	53%	49%
Previous commitments	35%	38%	30%
The time of the sessions I was interested in were inconvenient / outside my working hours	31%	30%	32%
Technical difficulties prevented further access	10%	8%	14%
The sessions were too discipline specific	9%	13%	3%
There were no other sessions that I was interested in	9%	9%	8%
Other	8%	7%	9%

Respondents who attended one or more of the Festival sessions were asked to describe their participation styles during the sessions. The large majority of respondents were actively engaged during the session and either asked questions or communicated with peers (41%) or listened closely without asking questions (28%). It appears that few participants only listen while working (19%) or drop in and out of sessions (5%) (Figure 2).

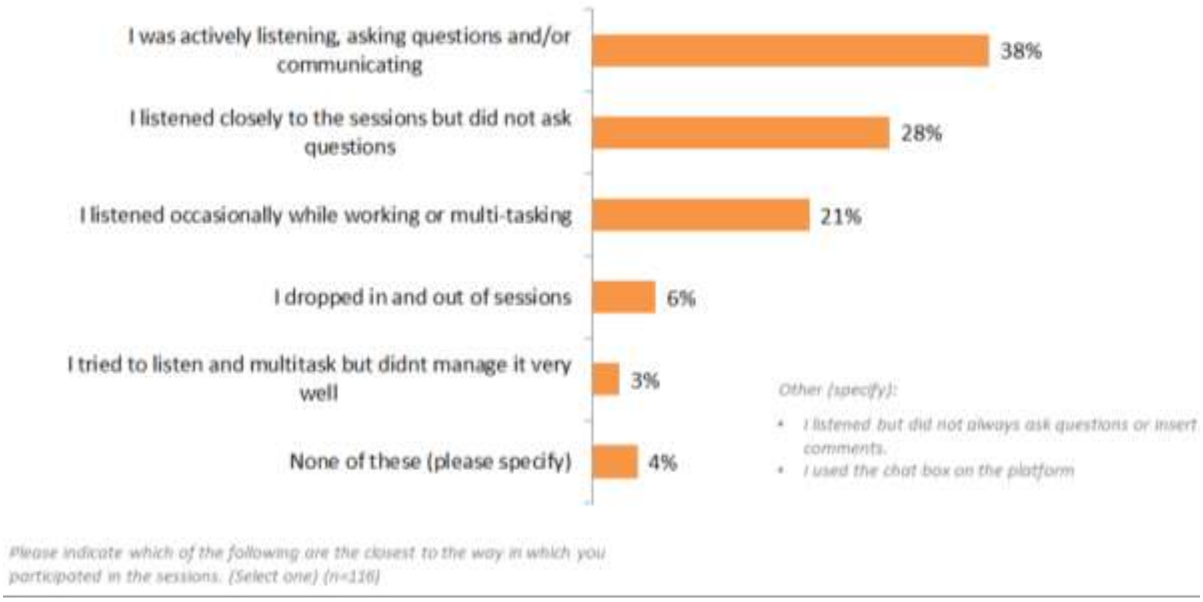

Figure 2: Actual trends for participating in sessions (Participants in Online Learning Festival, n=106)

Perceptions of the value and impact of the Online Learning Festival

Respondents were asked to provide insights through a series of open questions on their perceptions of the value and impact of the conference as well as their personal learning expectations. Preliminary analysis of the comments indicate that participants were intrigued by and valued the collaborative online experience offered by the Festival. Comments from the raw data include:

> This year was a truly collaborative endeavour. I was intrigued by the 24-hour format and the calibre of hosts and presenters. Excellent speakers and panels, who know how to conduct themselves in synchronous environments, and well trained moderators. Enlightening and thought-provoking.
>
> This has been extraordinary and probably the best single experience in my 10 years in Higher Education. So much breadth and depth and such a sense of connectedness.

Respondents have indicated that online learning events in this format are an attractive avenue for exploring new learning ideas, remain up to date with the latest trends in educational technology, feel a sense of community and network and connect with peers in similar fields. This suggests that the format employed for the Learning Festival does meet the needs of potential participants and is able to provide a sense of collaboration and community that participants value.

New learning that occurred as a result of the Online Learning Festival

As mentioned previously, the primary rationale for the evaluation of the Festival was to determine the extent to which new learning occurred . Respondents were requested to provide insight into any new learning they experienced or any new questions that have occurred to them as a result of participation in the conference. Forty one participants indicated that they experienced new learning as a result of the conference and twenty were interested in tracking the actions identified from these learnings in future surveys.

A large number of new learnings were focused on technology specific issues and were presented as broader thoughts rather than specific learnings or actions. Examples of these include:

> A high level understanding of the direction technology is taking in learning and a stepping stone into further studies.
>
> I learned a lot about virtual worlds, professional virtual learning, e-pedagogies and technology-enhanced learning. I also discovered how Blackboard worked and found it was a wonderful tool.
>
> I thought about the use of technologies in new ways. Also, I had a greater insight into the challenges facing some disciplines.
>
> Specific approaches for developing learning materials; better understanding of teaching practices internationally.

These findings suggest that either the evaluation instructions were not sufficiently clear or that the summative online evaluation tool was not the appropriate method for identifying learning and action as a result of the conference. Further probing into the responses of participants who agreed to participate in future surveys may provide a more detailed response.

Preferences for future formats of online learning events

Participants were asked to describe the barriers that they experienced most in attempting to attend online events in general. Difficulty in scheduling time off from work was the number one reason provided by nearly all respondents (80%). This suggests that there is scope to alter online learning events, particularly lengthy conferences, to be more flexible and more easily accommodated within busy work schedules.

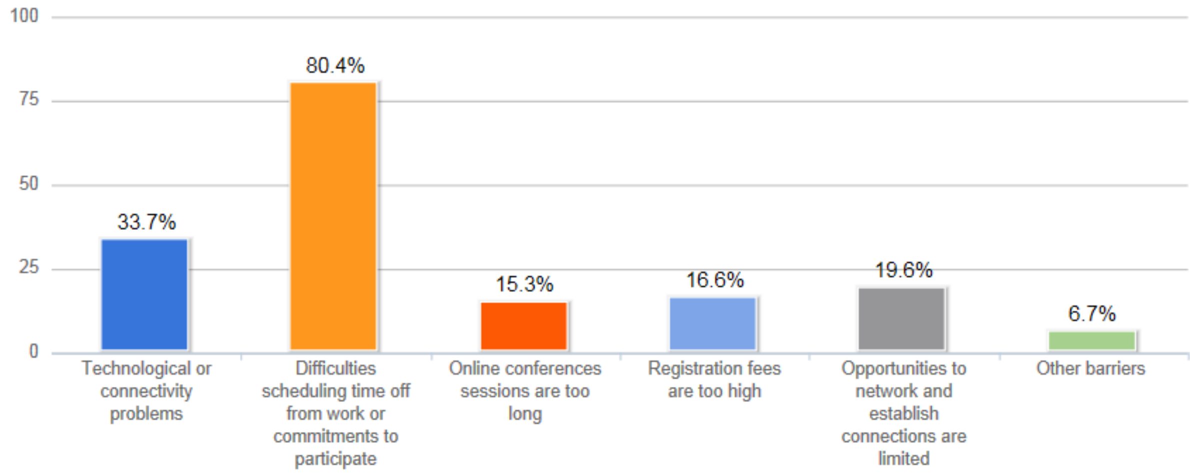

Figure 3: Barriers experienced in attempting to attend online events in general

The answer to this concern may lie in the development of online conferences that utilize both synchronous and asynchronous features. Respondents were requested to select their preferences for alternative formats for online conferences and a large proportion (34%) preferred events that included asynchronous components such as pre-recorded videos but also included synchronous features such as access to the presenter for questions in real time. Events that follow this format may satisfy the requirements of conference delegates to interact and collaborate with peers yet still enable flexibility by allowing them to watch the pre-recorded sessions at an earlier stage in their own time.

Figure 4: Preferred approaches for future Online Learning Festivals

Conclusion

Higher education is changing rapidly to address the imperatives of digital futures. Developing knowledge and experience of how to effectively lead and support online learning experiences and interaction as well as develop digital communities is critical to enhance skills and practice that can be applied across diverse contexts, despite geographical boundaries. This paper has provided an overview of a partnership between three tertiary institutions located across the globe that have collaborated to provide new opportunities for facilitating online learning, access to digital communities and networking for professionals. As the education landscape and learning needs of future students and professionals evolve and change, learning institutions will greatly benefit from joining together across global boundaries to provide unique and effective learning experiences. The paper also presents an overview of the methodology and preliminary findings of an evaluation conducted to assess the value and impact of these initiatives in stimulating new learning.

The results from the evaluation suggest that the Festival format presented in this paper has the potential to engage and connect participants in geographically dispersed locations and encourage future collaboration and communication. The potential for these events to create New learning as defined by Chapman et al. (2007) is however still uncertain. The findings further suggest that there is scope for improving the format of online conferences particularly lengthy sessions that require extensive time commitments from participants. The manner in which participants engage with online sessions, including the extent to which they actively participate and collaborate with peers synchronously requires further insight. This will assist conference developers in identifying formats that are able to capture the attention of participants for the full session time and result in new learning's and a tangible impact on practice. Online conference technologies have the potential to contribute significantly to enhancing professional conference experiences. However, additional research into participant behaviour and further innovation in delivery formats is required.

Using e-readers to increase access to course content for students without Internet access

Angela Murphy
Australian Digital Futures Institute
University of Southern Queensland

Neil Martin
Australian Digital Futures Institute
University of Southern Queensland

Helen Farley
Australian Digital Futures Institute
University of Southern Queensland

There have been mixed reviews about the potential of e-readers to enhance higher education. At first glance, e-readers appear to have significant potential to provide students with access to course content and learning materials. There are a number of considerations and obstacles to be addressed, however, before these devices are ready for widespread adoption. This paper reports on a pilot study using e-readers to provide students without internet access, with access to electronic course content. Course readings were converted into ePub format and were made available to a cohort of 16 incarcerated students via e-readers. This paper provides an overview of the steps undertaken as well the challenges and obstacles encountered in converting the readings to ePub format.

Keywords: e-readers, diversity and inclusion, ePub, incarcerated students, digital divide

Project context and background

Since the release of the Amazon Kindle in November 2007, the popularity of e-readers and e-books has increased rapidly and a growing number of publishers are producing content in multiple formats to service the e-reader market (Stone, 2008). E-readers are low-cost, energy efficient devices capable of storing a large number of journal articles, course readings, dictionaries and other course resources. They also enable students to bookmark, search and take notes. Consequently, these devices have the potential to overcome a number of challenges within the higher education (HE) context including the rising cost of textbooks and the increasing demand for mobility and flexibility in learning. Research has identified a range of challenges and barriers that hinder the widespread uptake of e-readers in HE (Gerlich, Browning & Westermann, 2011) including difficulties in obtaining copyright permission to replicate materials, and difficulties in converting documents from pdf format to ePub.

This paper reports on the processes, challenges and successes experienced during a pilot project to provide a small cohort of incarcerated students with access to course materials in ePub format on e-readers. The increasing reliance of distance learning institutions on elearning has resulted in greater challenges for incarcerated students attempting to participate in HE, as offenders are excluded from enrolling in any programs that require learners to consult resources on the internet (Mortimer, 2008). Formal education and training delivery to prisoners is currently provided in non-digital forms using large volumes of printed copies of the course materials (Dorman & Bull, 2003). This is costly for universities to assemble, print and post, and cannot incorporate all of the learning support resources of the course. The aim of the pilot project was to attempt to overcome some of these challenges as well as provide opportunities for incarcerated students to develop critical e-literacy and e-research skills (Farley & Murphy, 2012).

Conversion process for course materials to ePub format

Course materials from a Tertiary Preparation Program (TPP) course *Studying to Succeed* at the University of Southern Queensland (USQ) were made available in ePub format to 16 incarcerated students on two types of e-Readers; the Sony PRS-350™ and Sony PRS-300™. The majority of the course materials were originally only available in PDF format. PDF does not display optimally on some eReaders and users cannot resize and reflow the content to meet their preference. As previous research has indicated that functionality and ease of use are particularly important to students (Mealer, Morgan & Williams, 2011), it was decided to convert the PDF documents to ePub (via an intermediate RTF conversion step).

Table 1: Overview of the process for conversion of PDF documents to ePub

Obtaining copyright permissions	The use of a number of the published journal articles required negotiation with publishers to make the readings available on the e-readers. Permission was obtained for all but two of the readings. These readings were not included in the e-readers.
Conversion to ePub format	Apple Pages was the software utilized for content conversion. A template was set up in Pages and the course content embedded. Content styles such as headers and captions were applied to the text and images resized as appropriate. An issues log was created to record problems along the way. All ePub files were uploaded onto the Sony eReaders. Cumulatively, 79 ePubs were created of which 61 were course readings, 17 module guides (the study book divided up), and the course introduction book. If printed onto A4 the course material would amount to approximately 750 pages. In this trial that would amount to 12,000 pages of printed text.
Formatting	A Pages template “ePub Best Practices” was customised and adapted to USQ style. The use of ePub allowed the students to resize and reflow the documents.
Use of images and tables	Larger tables and images did not always display correctly on the e-readers. This may be a limitation of the device and Pages output. Images were resized and, screen grabs of the tables were taken from the original PDF and embedded into the tables.

Challenges experienced and early successes

In using Pages most content was relatively easy to convert into ePub format, however a number of technical challenges were experienced and solutions sought.

- Some materials e.g. Learning Activities materials required extra mark up (such as a Horizontal Line) to distinguish them from the main body copy. This is due to the homogenous nature of ePub and whilst this advantageous in terms of allowing the reader to reformat and reflow the content to meet their own preferences, some control over how specialised content is formatted is lost.
- Direct conversion to ePub from Open Document formats (ODT) proved impossible. The solution was to convert materials to Rich Text Format first.
- Some text sizing was inconsistent following conversion and required a manual sweep of the document to fix. A better solution is to check the HTML markup in the ePub against the corresponding style sheet using a tool such as Sigil, although this wasn’t done in this project due to the lack of appropriate expertise of the person converting the materials.
- Readings were initially intended to be in a single large ePub file. However, the Pages software became slow and unstable due to the sheer size of the file and files were broken up into individual ePubs. The final checking of materials is time consuming and any future work needs to look for efficiencies. It is anticipated that as conversion software matures this process will be a lot easier.

Early feedback from pilot participants has indicated that the e-readers have contributed significantly to increasing satisfaction with learning and accessibility of course materials. Students received initial training and support from prison education officers in the use of the devices and the learning curve and time required to adjust to the device was less than anticipated. Initial feedback from incarcerated students is that the e-readers provide access to learning materials during times of lock down and are convenient to use for study. The e-readers have also had the added benefit of introducing long term incarcerated students to mobile technology devices.

Conclusion

Initial indications suggest that course readings made available in ePub format on e-readers to students will assist in overcoming some of the challenges experienced by students without internet access. E-readers preloaded with course materials and additional learning resources can be posted to students without internet access at minimal costs and is more cost-effective than posting large quantities of printed materials. E-readers can also be preloaded with a larger number of additional resources such as dictionaries, including multilingual dictionaries and open educational resources. More advanced e-readers even allow the inclusion of audio and video resources. Within correctional centres, e-readers are a viable alternative to expensive textbooks that are often a barrier to participation in HE and also assist in overcoming the restrictions on physical space available for textbooks in cells. A number of challenges need to be overcome before the use of e-readers is sustainable. These include the availability of readings and journal articles in more user friendly formats such as rich text or html and the development of dedicated software and automated workflows to enable bulk conversion of documents to ePub format. Copyright considerations are the greatest obstacle to the success of these initiatives due to the restrictions imposed by publishing houses regarding the formatting changes that may be required for effective conversion to ePub or lack of permission for conversion altogether.

Sustainable learning through formative online assessment: using quizzes to maintain engagement

Lynette Nagel
Department for Education Innovation
University of Pretoria

Lanise van Eck
Department of Financial Accounting
University of Pretoria

Due to pressure to deliver more Chartered Accountants, the pass-rate of first-year accounting students had to increase. Students who did not take accounting at school particularly needed extra tuition and support to reach the required standard. Poor success rates could be attributed to insufficient theoretical learning and poor time management characterized by cramming before tests. The intervention that aimed to redress those problems was weekly online quizzes that students could complete in their own time that contained feedback and easily understood explanations. In order to create and sustain an adequate database of suitable questions, the tutors who facilitated additional work sessions and understood the pitfalls in the theory, helped the lecturers to compile the questions and participated in quality control. Quizzes and feedback helped students to pace themselves, understand the terms and prepare for tests. The pass-rate increased from 57 to 75%.

Keywords: Financial Accounting, online quizzes, feedback, tutors

Introduction

Universities have a dual role in serving their communities: in the first place to produce knowledgeable adults who are flexible life-long learners, who can solve problems that do not yet exist, as well as very specifically trained professionals who meet the standards and ethics of their profession and serve a well-defined niche in the economy. Chartered accountants (CA) fall also into both categories. The University of Pretoria is under enormous pressure to meet their target of delivering a certain number of qualified students to this profession, irrespective of the quality of the first-year intake. At the same time, demand for chartered accountants increased and started to exceed the supply, while the professional body determined and maintained the standards and curriculum. Students were also entering university without adequate preparation. Recently the school curriculum has changed to outcomes-based education contributing the first group of scholars to tertiary education in 2010. One of the main objectives of the new school curriculum was to focus more on skills such as group-work and less on subject content. Numbers of matriculants who met the selection criteria of subjects and performance level to meet the demand, were dwindling. This university decided to allow students with enough credits into the CA stream, even if they did not take accounting at school and increase the student throughput.

The research questions for this paper are the following: Can online quizzes effectively stimulate engagement of students to study a theoretical subject? The second question is: Do students benefit from doing online quizzes in their own time?

Literature

Dewey (1938) criticizes traditional education for lacking in holistic understanding of students and designing curricula overly focused on content rather than context. If this approach is taken too far, students have inflated self-confidence that is not based on real abilities and knowledge of the subject. There is ample evidence that students master material ineffectively if they do not receive any guidance. “Instructional approaches that place a strong emphasis on guidance of the student learning process” (Kirschner, Sweller, & Clark, 2006, p. 75) are believed to be superior in preparing students towards acquiring sufficient prior knowledge to pace their own learning. While students perform best in situations where they are tutored individually, this is not feasible in very large classes.

Human individual tutoring is both the most effective and most expensive way of improving student learning, making it unsustainable when resources are limited. Bloom (1984) found that mastery learning in a class allowed students to learn the material as well or better than the individually tutored students when they received the same instruction as a standard class, followed by formative tests with feedback and corrective procedures. He showed a 2 sigma improvement in learning over a standard class who did not do the mastery learning (Bloom, 1984). According to Frick (2008), students value tutored classes to the extent that they derived benefits from them. The different roles of tutors are consistent with Schmidt & Moust (2000) who propose that the goal of a tutor is to encourage critical thinking, help the students to organise their knowledge, clarify any misunderstandings and explain difficult concepts, providing quality and sustainability in the support of the learning process.

Using LMS-based discussions to provide a first line of communication between students and tutors, makes better use of the scarce resource of personal tutors. Online discussions can provide a platform for higher-order thinking, if the right leading questions are posed and suitable facilitation accompanies the discussion (Bhagyavati, Kurkovsky, & Whitehead, 2005; Meyer, 2003). The greatest limitation to using online discussions in large classes is time, both from a student perspective, if they have many other subjects to tend to, and facilitator capacity, having to fulfill the roles of social and pedagogical facilitator, manager, and technical specialist (Liu, Lee, Bonk, Su, & Magjuka, 2005). Class sizes can be prohibitive, as the ideal facilitated online groups is somewhere between 12 and 30 (Arbaugh & Benbunan-Finch, 2005; Orellana, 2006; Tomei, 2006). The larger a facilitated group becomes, the less engaged students become as they do not feel they have a voice (Roberts & Lowry, 2006). Online discussions are therefore unsustainable when resources are insufficient, or classes to big.

It is important that newly acquired data should be transformed into retrievable knowledge that is stored in long-term memory through rehearsal, retrieval and metacognitive monitoring. Metacognitive skills are responsible for setting learning goals, determining learning strategies, monitoring progress, and making adjustments as needed. Due to poor school instruction (Spaull, 2012), many South African students have been taught erroneous concepts and are unaware of their own misconceptions. Learners with poor metacognitive skills, who do not know what they do not know, profit from support in monitoring their learning. (Clark & Harrelson, 2002). For example, frequent skills tests to assess knowledge help these learners spot topics that require additional study (Clark & Harrelson, 2002). Diagnostic assessments early in a course also show students whether their knowledge and study efforts are sufficient, providing timely warnings to adjust their learning strategies (Campbell, 2006). Online quizzes with automated feedback provide students the means to perform better than they would on their own (Corbett, 2001). When classes are too large for using one on one tutoring or even facilitated discussions to pinpoint and correct knowledge gaps, online quizzes might fulfill the same function in a way that is more sustainable towards the future.

Context

Who are the students

Financial Accounting is one of the four core subjects in the studies for Chartered Accountancy (CA), a highly challenging, but rewarding course for which students are selected on merit of school grades. Proficient students, who obtained more than 60% for accounting at school, were eligible to enroll for the mainstream accounting subject FRK 100 in the CA stream. According to Thijs, van der Vlier & Zaaiman (2003) the validity of matric results can influence the effective selection of suitable candidates for higher education institutions. Teaching standards at the majority of South African schools are deteriorating, as only 38% of children who started school in 2000 passed matric in 2011, largely due to not acquiring foundation skills at school (Spaull, 2012). Students were therefore becoming less prepared for University study.

Over the years it also became evident that some students who were allowed into the CA stream on the basis of good school grades, were often not equipped to pass financial accounting. In order to identify more accurately the students who were at risk, the Department of Financial Accounting implemented a proficiency test at the beginning of 2012. All students who had passed accounting at school with an average of more than 60% had to write a very basic accounting proficiency test. This “screening” process categorised the students on the basis of their *actual* abilities.

The University of Pretoria is currently the only institution in this country that allowed students into the CA program without taking accounting at school. In 2001 it instituted FRK 101, a special course in accounting that offered supplemental instruction to students who did not attain 60% for accounting, but otherwise qualified for selection, as well as those with merit that did not take accounting at school. Students who did not get the required marks in the proficiency test from 2012 on were also encouraged to transfer to FRK 101.The number of students increased steadily from 75 in 2006 to 132 in 2012 (figure 1). These students needed individual attention and additional help as they had to cover both the basic school accounting curriculum as well as the standard first year curriculum in one year. This differs from bridging programs in other faculties, like Engineering, where students could spread the first years of their studies over an additional year.

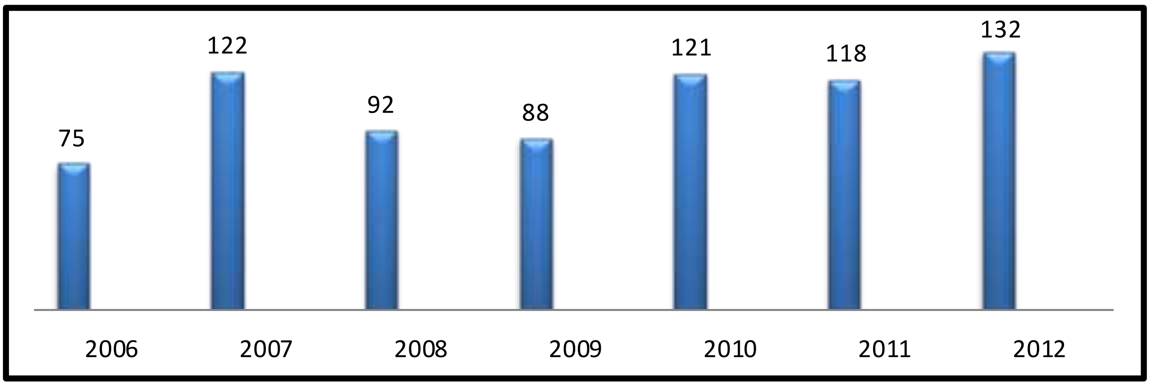

Figure 1: Number of students enrolled for FRK101 over 7 years

When throughput rates in first-year courses came under scrutiny in 2009, financial accounting was identified as a High Impact Module (HIM) due to high student numbers and a pass rate of less than 70%. The department therefore launched a project at the end of 2010 to improve the performance of the students. The project included focus group interviews with students stratified according to their semester marks, to shed light on their poor performance. The reasons mentioned most often were: underestimation of the amount of work, their inability to plan their time, underestimation of the importance of the subject for continuing to the second year of study (a pass grade was required for accounting), poor understanding of the importance of this subject in the overall qualification, and not studying the theory before attempting problems, as well as poor metacognition (Nagel & Oberholster, 2011).

Based on the findings of the focus group interviews a number of interventions were proposed for implementation in 2011 (Nagel & Oberholster, 2011, p. 382), namely

- a clickable mind-map of all the courses in the 4 years of study, explaining how they articulate horizontally and with the next academic level
- a scrolling banner and pop-up windows reminding students to study their theory before attempting problem-solving
- online glossaries of terms explaining subject terminology in lay language
- a weekly multiple choice test with explanatory feed-back
- an Accounting board game (not discussed in this paper).

The first three interventions were implemented immediately in the LMS for the benefit of all the CA students and required only maintenance thereafter. The latter two initiatives were earmarked for piloting in FRK101 (no accounting at school) during 2011, as their group was smaller and more manageable than the other group.

Teaching and learning

When the students were asked in the interviews in 2010 whether they would prefer to spread the workload of the first year over an additional academic year, they rejected it as a solution, as the total course already took so many years. They preferred a concentrated approach that was subsequently introduced. In order to cover both the school curriculum and catch up with the mainstream students, the FRK101 students had 12 lectures per week during the first quarter and 8 lectures per week during the second, third and fourth quarter, whereas mainstream students had only 4 lectures per week throughout the year. In addition they had 2 work sessions (tutor classes) of 2 hours each per week that was a problem-based discussion session. Much of the extra work was limited to the first semester. The FRK 101 students took the same formal tests as the mainstream students and wrote an additional 16 class tests during the year.

The board game required much time and effort during the first quarter of the academic year, and although it was perceived as very beneficial by the students, it will need streamlining to improve its sustainability before it can be rolled out for the mainstream class, and is therefore beyond the scope of this paper.

Compiling and implementing the quizzes

In this paper we focus on the multiple choice tests (quizzes) with the feedback that were initially rolled out in 2011for the hundred and thirty-two FRK 101 students, who faced the greatest learning challenge. The ongoing quizzes were aimed at sustaining students' engagement with the learning content, forced them to study the theory on time and to keep up with the pace of the course. Each of the 17 quizzes contained 5 randomly allocated questions with randomized options addressing the current week's theoretical classes, had to be completed in 10 minutes and was available for a period of six days. The quiz was selectively released only to FRK 101 students who received two attempts which they could complete at a computer of their own choice, whether on campus or elsewhere. The highest grade of two attempts was captured in the LMS grade centre, and the average of the quizzes would contribute 20% of the semester mark which also included class tests and formal tests.

The challenges regarding the creation of the questions were to have adequate numbers of high quality and relevant questions; to identify concepts that the first-year students had trouble understanding and to include questions that reflected the newest legislation. The last aspect was the lecturers' responsibility. Each test was compiled in two languages. The goal of the quizzes was to be a learning exercise for the student through the explanatory feedback associated with each question that elevated the quizzes to an important learning event. Feedback mostly contained clear explanations of the correct answer and the key concepts, or explained formulas for calculated questions. Care was taken to identify the "catch" in each question. The feedback was aimed at the majority of students because it was formulated in easy to understand language at the level of the students, did not repeat the textbook or the class notes, and would help those who did not know sufficient subject terminology. Lecturers did not have the time to compile such extensive questions; therefore the help of tutors were enlisted.

Tutors were selected from the previous year's FRK 101 class, and their prime task was to facilitate the twice-weekly work sessions. During these work sessions/tutor classes the tutors engaged in problem-based learning. They presented a problem that initiated the learning process, followed by discussion in a group of 15 - 25 students. The students came to the work session with only the knowledge that they obtained during formal lectures, while the tutors had a thorough preparation. At the beginning of the year the selected tutors received extensive training in how to set high quality valid questions and feedback. The tutors remembered which concepts were difficult for them and were up to date with the current first-year content through the work sessions, and knew which sections of the work were problematic. Being mostly second-language English speakers, they shared the linguistic challenges of the majority of the students. Tutors whose first language was Afrikaans were bilingual and translated the English questions into Afrikaans. Before each quiz opened for the students, the question bank on the topic was uploaded into a training course on the LMS (WebCT Vista in 2011) where the tutors and the lecturer had to answer all questions. After checking on the question statistics, overly difficult or ambiguous questions and feedback on which consensus was not reached, where corrected, after which the adapted question bank was exported to the student course. When some enterprising tutors used commercial questions obtained from textbook question banks, it was very difficult to match them with the current week's topic and their feedback did not meet the criteria, hence they were not used again. Tutors were therefore an excellent and sustainable source of valid questions.

Quizzes not only encouraged students to revisit notes before writing, teaching also improved due to the question statistics that were drawn from the LMS. The quality control before the students took the quizzes minimised mistakes and poorly formulated questions. When students consistently chose a wrong option in a question it rather indicated poor understanding, misconceptions, or unclear instruction, all of which could easily and quickly be remedied in class, instead of having to wait months for results of a semester test. Salient questions could be included in revision tests at a later stage to monitor the improvement in understanding.

Methodology

We followed a development research approach (Reeves, 2003), as the problem was ill-defined and needed a holistic approach towards improving the educational situation in a case study consisting of a first-year Accounting course. Numerous interventions were proposed to address specific aspects of the problem, which were then evaluated and refined, before further interventions were implemented. In 2010 we conducted focus group interviews with a total of 58 purposely selected students and after analyzing the data, interviewed the lecturers on plausible innovations. We also investigated the quizzes in the LMS in 2011 and obtained the grades of the students who participated in the 17 quizzes and the semester and final examinations over three evaluation periods. In this paper we report on how 91 of the 118 FRK101 students experienced the online quizzes in 2011 as captured by a survey with objective and open-ended questions in the LMS. The objective items consisted of statements with 3 options ranging from affirmative, somewhat affirmative and negative, depending on the question wording. Quantitative feedback of 26 of the students who repeated the course were separated from and compared to those of the 65 first-time first-year students. The differences were analyzed using SPSS, and Pearson's R values and Chi square were calculated. We present only results of questions where highly significant results were obtained.

Findings and discussion

The suitability of using online quizzes was confirmed when students indicated that they all have access to computers to take the quizzes, and nobody said it is too much trouble, even in the light that they already had many more sessions and assessments than the mainstream students.

The initial interviews indicated that students underestimated the importance of studying the theory in financial accounting, a problem that was then addressed on several fronts (Nagel & Oberholster, 2011). According to Frick (2008) the new National Curriculum Statement for schools (grades10 - 12) places the emphasis on developing certain skills rather than focusing on content knowledge. Students were thus not used to studying, understanding and applying the theory, which forms the basis of accounting. It also became apparent that the students struggled to keep up to date with the work and they found the volume of work daunting. The quizzes were introduced to FRK 101 (students who did not take accounting at school) in 2011 to address these problems. The feedback from the students regarding the quizzes were overwhelmingly positive, with the exception of about 6% of the respondents, they indicated affirmatively that

- they studied the theory before the first or second quiz attempt
- they benefitted from the quizzes and the immediate feedback on each question
- quizzes and feedback helped them to learn for this subject and
- quizzes confirmed how well they understood the work
- they regarded the scope for every week's quiz as suitable (not too much or too little work), as the test covered a limited section corresponding to a topic that was completed before the next one was started. This helped students to manage the large volume of work required for semester tests.

These results showed that, except for a small group of students, practically everybody found the quizzes beneficial. The results show that the quizzes do address the two main problems that students face, namely realizing the importance of theory and learning to manage the large volume of work. In order to gauge the benefit of the quizzes to different profiles of students, we separated the responses of students who repeated the course (26) from those who were first-time first- year students (65). The repeaters was a valid "control" as they had not experienced the quizzes or any of the other learning innovations before. Dividing the data thus exposed three patterns: for some questions, there was no difference in responses between the two groups, while for some questions there were significant differences, some aspects of the quizzes reportedly being more beneficial to one group, while others benefitted the other group more.

For the question regarding the scope of the work covered by the quizzes, the responses were similar in the two groups, with about 92 % of both groups finding it suitable. This was important, as previously students only studied large chunks of work for semester tests that were spaced far apart, and the previous year's unsuccessful students indicated in the interviews that they could not master such vast amounts of work. On the question about the spacing of the tests, 70% of both groups thought that the spacing of the quizzes was suitable, while 30% would have preferred them to be further apart.

One of the core issues in the course had been their lack of studying theory, and students being unable to catch up after the first semester test when they realized the importance thereof (Nagel & Oberholster, 2011). The feedback on the quizzes indicated that both repeaters as first-time students now studied theory for the quizzes after they have been bombarded with slogans to study theory before attempting problems. There was no difference in the distribution of how diligently they studied. Of the repeaters, 46% *usually* studied the theory, while another 46% *sometimes* studied theory. The non-repeating students indicated that 48% usually and 44 sometimes studied theory. Likewise there were no significant differences in the pattern of studying theory before a second attempt at the quiz. Significantly more of the students who studied the subject for the first time

(86%), wished to have a second chance to complete each quiz, compared to the repeaters' 76%. Even though the quizzes contributed only 20% to their semester mark, this might indicate that the first-time first-years aimed at higher grades than the repeaters. The class average grade for the 17 quizzes was 61%, which was higher than any of the averages for the written tests. Considering that they had two attempts at a quiz on each subject, and they could consult any supportive documentation as they wished, the quizzes were still challenging, but provided an opportunity to perform quite well. This was less so in the written tests, as FRK101 wrote the same tests as the students who had accounting at school and were at a distinct disadvantage up to the final examination. As quizzes provided about 10% of the final mark, where students performed about 20% better than in written tests, it was not enough to account for the nearly 20% improvement in pass rate in the class who wrote the quizzes.

Highly significant was the perception of 81% of the repeaters who *generally* found the quizzes useful while only 64% of the first-time students found them *generally* useful, and 32% found them *sometimes* useful. This was an important finding, as the quizzes were aimed at students who were at risk of failing, and the repeating students could compare the quizzes' usefulness with what they experienced the previous year when they could not pass the subject. Judged by the student opinion, the quizzes as intervention were on target to support at-risk students.

Students also had divergent perceptions of the usefulness of the feedback, with 84% of the repeaters and 69% of non-repeaters finding the feedback *generally* useful, and 29% of non-repeaters only *sometimes* finding it useful. This is likewise an important finding, showing that the feedback that is aimed at the less successful students, is perceived as important by them. The two groups studied feedback with similar frequency.

When asked to rate whether the quizzes helped them to prepare for formal tests, 38% of repeaters replied affirmatively and 38% reckoned that it helped *somewhat*. Quizzes *generally* helped 50% of the non-repeaters and *somewhat* helped 33% in preparing for tests. From these findings, it seemed that the first-time students were unsure about what kind of questions to expect in tests, and the quizzes ameliorated their anxiety, whereas the repeaters who had previously written the formal tests and exams, were less reliant on quizzes to prepare them for this aspect of assessment.

Qualitative analysis of the open-ended responses to the surveys, confirmed the findings of the survey items. In addition, students requested to have more questions in the quizzes, or have them more frequently, like twice weekly. Requests from a number of students at the end of the year for more challenging questions indicated that the standard of those students had increased to a level where they were not merely concerned about passing the subject, but really wished to improve their grades further. Another request was to include more calculation-type questions. These findings were heartening, as these students already took many more class tests than the mainstream students, and nevertheless valued the online quizzes so highly, as to request more.

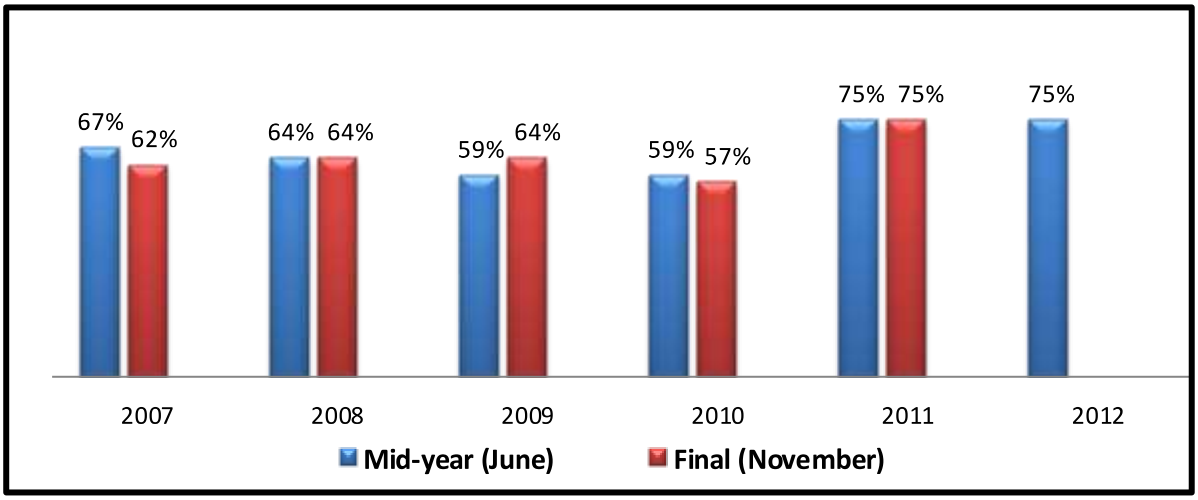

Figure 2: Pass rates of students without accounting at school

Students' self-reported opinions of the usefulness of an intervention could not be taken as only proof that the objective of improving a low pass-rate was attained. Figure 2 shows the mid-year or semester mark as well as the final mark of this class over five complete years and the first semester of 2012. It is evident that there was a highly significant improvement in pass rate after the implementation of the online quizzes in 2011. Preliminary grades from 2012 confirmed that the present students are likewise benefitting from the interventions. From the pass rates shown in figure 2, it is evident that students who did not have accounting at school, were in a good position to pass Financial Accounting in the chartered accounting stream, and the University could expect a 75% pass rate from this course. The subject should not be classified as a high impact module after the current year.

Conclusions

This paper showed how an integrated and responsive approach utilizing simple online quizzes in an LMS can improve first-year students' engagement with the theoretical side of accounting, leading to improved outcomes. Students who did not take accounting at school were at a grave disadvantage when they enrolled for financial accounting in the chartered accounting stream. Interviews with unsuccessful students revealed that the students underestimated the importance of studying theory, in part due to outcomes-based school education that focused less on mastering content. Students also had poor study habits that consisted of cramming large amounts of work just before tests. The effect of these habits was that they could not master such huge volumes of work simultaneously. As intervention, the department instituted informal online tests that paced the students and encouraged them to study the theory before attempting to solve problems..

Feedback from the students at the end of 2011 showed that students found the quizzes appropriate in frequency (weekly) and scope (covering the current week's work). In contrast to the previous year, practically all students reported that they studied their theory before attempting the quizzes, even before a second attempt, which was also highly valued. The students who had failed the subject the previous year found the concomitant feedback that explained the concepts behind the questions in easy terms, of more benefit than the first-time students did. More of the repeaters also felt the quizzes helped them to master the work than the others. The high value the quizzes had for the repeating students, (who did not have such quizzes during their first attempt at this subject), showed that the quizzes specifically benefited students who were at risk of failing, while more than 90% of all students benefited to some extent. The first-time first-year students particularly found the quizzes beneficial to prepare them for writing formal tests. We can conclude that students across the board benefited from the quizzes, not only to pass the subject, but to increase their grades, a finding that was confirmed by open-ended responses wherein students requested greater numbers of and more challenging questions.

The benefit of the quizzes was evident in the increased pass-rate of the group who did not have accounting at school from 57% to 75%. The sustainability of the improvement is seen in the following year's half-year mark that promises a similar pass rate. It is further seen in the up-scaling of the quizzes from a class of 118 in 2011 to the whole CA stream consisting of 581 students. Increasing the database, updating of questions to reflect changing legislation and controlling quality is totally sustainable, as the tutors are a readily available resource doing an admirable task. The nature of the formative assessment that provided feedback enabled many more students who were at a great disadvantage, to catch up with a challenging subject and complete it successfully.

Based on the success of this intervention, the question database is currently being expanded and students in the mainstream accounting course are also writing weekly online quizzes. There are also plans to extend the quizzes to the (more than 2000) students in the commercial stream of Bachelor of Commerce in an attempt to increase their engagement with the subject and improve their success rate. The intervention was sustainable as it made optimal use of the limited people-power in the form of tutors, tapping into their own experience as students and facilitators. Sustained engagement prepared students also for the future as life-long learners.

Engaging students in writing: online blogs versus conventional paper – insights and considerations

Shanthi Suraj Nair
Department of English
Beacon Primary School

Lee Yong Tay
Department of Research & ICT
Beacon Primary School

This research paper explores the difference between conventional composition writing and writing of composition on online blogs by 224, 6 classes of Grade 5 students in an elementary-level future school in Singapore. Students in this study are savvy information communication technology (ICT) users who have been exposed to one-to-one computing since Grade 1. A total of 4 written assignments were given to the students – two conventional paper and pencil and two online blogs written assignments. No significant difference was found in students' scores on the four written assignments and their penmanship. The submission rate for the conventional paper and pencil composition written assignments was 93.75% as compared to 75% for the online blogs entries. Although interviews with teachers seem to suggest that the ICT mode could facilitate the learning of higher-order type of learning, the significantly lower submission rate for the online blogs is of concern and interest.

Keywords: English writing, blogs, one-to-one computing

Background

This research study is situated in one of the three elementary-level future school in Singapore. The school adopts a one-to-one computing learning environment for its students from Grade 1. School supplies the computing devices for Grade 1 to 3 and students procure and have their own computing devices from Grade 4 onwards. The school's mission is to nurture and inspire its students to the best of their potential through innovative approaches in an engaging environment, leveraging on technologies and research.

Purpose

The main purpose of this research study is to look into the quality of students' writing in conventional paper and pencil mode and online medium. This study also looks into the quality of students' handwriting to ascertain whether students' penmanship would be significantly altered after prolong exposure and usage of computing devices.

The study resulted from a series of professional discussions based on simple anecdotal observations by the English Language teachers of the classes concerned that their pupils were writing freely, without inhibitions, and with greater pride when using their class blogs. The team of teachers decided to investigate if these observations were valid and could be supported by data. A working team comprising the head of information communication technology (ICT) and research, one of the ICT champions in the English department and the Primary 5 English language teachers was formed to discuss and conceptualise the plan for a study on pupils' writing habits, both on paper and the online blogs. It was decided that the team would ride on the expository text types that pupils had already been exposed to in Term 1 of 2012 and four journal topics would be explored. The ICT champion put together a simple work plan, which included the time line for the various assignments and some resources to trigger the class discussions for the topics identified. The English Language teachers then discussed the implementation plan before embarking on the project. The entire process lasted about 10 weeks; about 2 weeks for the initial discussion and conceptualisation, about 4 weeks for the implementation of the assignments and about 4 weeks for the evaluation and data processing.

Literature Review

Blogs are online personal journals which allow regular updating to take place. They share a common theme and content can be posted by one or more authors. Readers are given the choice to comment on the posts, promoting exchange of ideas between users. Besides its convenience and usage as open source, the outreach of blogs extends beyond physical interactions and provides opportunities to publish immediately. They are especially useful in language classes (Campbell, 2004; Grewling, 2004). Blogs can potentially bring, such as skills of communicating, sharing, analysing, reflecting and writing. Many other research studies have reported positive and encouraging findings on blogs and language learning (Boiling, 2008; Holliway & McCutchen, 2004; Izquierdo & Reyes, 2009; Merchant, 2005; Torrance, 2007).

Context

The whole cohort of 224 Grade 5 students from 6 classes took part in this research study. The classes were streamed according to their general academic abilities with the students' Grade 4 end-of-year assessments, inclusive of English, mathematics, science and their mother tongue language (i.e., Chinese, Malay and Tamil). 5-1 having students from the highest academic abilities and 5-6, the least. These 6 classes were taught by 4 different English language teachers.

The students were all given four written assignments with similar genre (i.e., argumentative type), two conventional paper and pencil ones and two that required them to write on blogs provided by the school. Each assignment was introduced through a simple class discussion of the topic which allowed the pupils to understand the various issues and implications of the subject matter. Pupils explored topics such as should smoking be totally banned, is it our responsibility to protect marine life, will our Mother Tongue languages (i.e., Chinese, Malay and Tamil) eventually die and if schools were the only places to learn. These topics were selected as they provided the context for the pupils to practise expository writing skills, a skill that they have been working on from the beginning of the term through their main English language curriculum, and were age-appropriate for the pupils. Choice of topics for the pen and paper assignments and the online blog assignments were random selections by the teachers. The topics on smoking and learning in schools were done on paper whereas those on marine life and mother tongue languages were done online. After the class based discussions, pupils were tasked to write their views either on paper or on the class blog. Each written assignment had to be completed within 30 minutes. Pupils could do any appropriate research or planning required, to organise and present their views, with supporting evidence, within the 30 minutes allocated for the task. The assignments were then graded by the teacher who taught the class according to a set of rubrics designed by the teachers. The rubrics included 3 main descriptor classifications-the issues, facts and content – with 5 marks for each category and a total of 15 marks.

This cohort of students had outperformed their counterparts in the country according to the University of New South Wales ICT skills assessment in both 2011 and 2012 and the differences were found to be statistically significant with the following statistics respectively: t (213) = 5.024, $p < 0.05$ and t (216) = 2.301, $p < 0.05$.

Preliminary Findings

Students' performance for the written assignments

The mean scores of the four writing assignments are presented in Table 1. Mean score for writing assignment 1 and 4 were done in conventional paper and pencil mode and the respective mean scores were 7.510 and 7.406. For writing assignments 2 and 3, they were done via blog postings and the mean scores were 7.224 and 7.748, respectively (see Table 1 for details).

A one-way repeated measures analysis of variance (ANOVA) was used to compare the 143 Grade 5 students who had submitted all four of their writing or journal assignments. $F_{max} = 1.542$, demonstrating homogeneity of variance and Mauchly's test indicated that the assumption of sphericity was not violated, Mauchly's W = 0.983, $p = 0.798$. The ANOVA results show that the students' scores differed among the four written assignments – two paper-based and two online blog-based, F (3, 426) = 3.296, $p = 0.020$, partial $\eta^2 = 0.023$. Pairwise comparison revealed that students' scores for writing assignment 2 – online blog-based (M = 7.224, SD = 2.749) differed significantly from assignment 3 – online blog-based (M = 7.748, SD = 2.896). No other statistical significant differences were found with the other writing assignments. The paper-based and online blog-based assignments students' scores did not differ significantly.

Submission rate of the assignments

Of the 224 students, 143 of them submitted all the four assignments, with 81 who had not submitted at least one of the assignments. For the conventional paper and pencil assignments 1 and 4, a total of 20 students did not submit their writing assignment 1 and nine did not submit assignment 4. In comparison, for the online blog writing assignments, 66 students did not submit assignment 2 and 46 students did not submit assignment 4. Table 2 shows the details of students who did not submit their writing assignments according to class and teacher. The chi-square statistics of χ^2 (3, N = 141) = 56.248, p = 0.00. As an index of effect size, Cohen's w was 0.632, which can be considered as large; suggesting that the non-submission rates amongst the four assignments vary significantly.

Conclusion

This research study aims to explore the quality of writing assignments via the conventional paper and pencil and online blogging modes. Although no significant difference was found in the quality between the conventional and online modes in the students' writing assignments, the study reveals an interesting phenomenon that is associated with online teaching and learning – lower assignment submission rates as compared to the conventional ones. In the follow up to this study, a more in-depth analysis of the interviews with the teachers and interviews with students from the various classes could reveal deeper insights into this phenomenon.

Taming the devil: A game-based approach to teaching immunology

Scott Nankervis
University of Ballarat

Grant Meredith
University of Ballarat

Peter Vamplew

Nina Fotinatos

Immunology is a complex field requiring rapid memorisation of numerous components. An in-depth understanding of cellular and molecular biology is required before even moderately advanced concepts can be taught. We sought methods that actively engage students and help develop new knowledge and consolidate existing concepts to support lectures. We created an interactive and entertaining prototype immunology computer game as a tool for learning and revision, with the ability to interactively cover course content outside of class that modern learners expect. Our prototype appears to be a successful study aid when used additionally to attendance at lectures. We seek to continue the development of the game in a higher education context, but also produce a modified version for a secondary school context, in an effort to raise the profile of this key health area and promote learning for the future through the study of the sciences prior to students entering higher education.

Keywords: immunology, computer game, educational gaming, serious gaming

Introduction

Computer games have made a significant cultural, social, economic, political, and technological impact on society and are no longer used simply to entertain (Newman, 2004; Kapp, 2012). Computer game-based learning strategies are a useful tool in primary, secondary and tertiary-level education (Begg & Dewhurst, 2005). In 2001, the Federation of American Scientists (FAS) began gathering research about how technology could be used to transform education. Such technology is useful in complex, high content curricula that are difficult to grasp for a variety of legitimate reasons (FAS 2009). Effective learning and teaching systems that engage next-generation scientists often include an element of computer gaming. Such systems include pedagogy and instructional design, building physically correct interactive simulations, dialogue and question management, learner modeling, and tools for assembling and constructing learning systems from these components. The current literature indicates that learning through game-based approaches results in higher rates of knowledge retention and comprehension as opposed to the traditional paper-based pedagogues (Ke, 2009; Sitzmann, 2011).

The inherent difficulties in the study of immunology have been encompassed by Tanne (1990) with her quote:

> Immunology is an invention of the devil, who is making it up as he goes along because he's not too clear about this stuff either.

The immune system is a collective process of cellular and molecular interactions within an organism to protect it itself against negative outcomes. It is an essential element of many human body-associated studies including medicine, physiotherapy and alternative therapies. New terminology, interactions and reactions, systemic relationships and staged approaches for complex cellular insults (autoimmune diseases, pathogenic organisms etc) complicate mastering the concepts of immunology (study of immune system).

In 2004, secondary school teachers in the United States expressed a desire for assistance with teaching strategies specific for immunology curriculum. In 2004, The Federation of American Scientists lead a collaboration with immunologists (scientists studying immunology) and graphic art experts to design a computer video game to address this missing literature in learning and teaching for the future. The FAS (2009) developed program, Immune Attack™ has subsequently been downloaded by 9000 secondary school educators and has moved into an evaluation phase: measuring the impact and effectiveness of the game in controlled school environments.

Although there are divergent streams of game learning (game-based versus game-informed), the key is to ensure that learning remains fun and is an effective tool in helping students understand new sets of skills and knowledge that are applicable in related disciplines (anatomy, physiology, infectious disease etc)(Begg & Dewhurst, 2005). Game-informed learning places the participant not only at the decision making level, but also reinforces strategies, concepts and interactions within the context of the curriculum. Medical students are regularly exposed to such interactive programs that focus on curricula (simple game role-play) but also disease simulation (complex game role-play), which requires pertinent and correct decision-making skills to collectively meet the desired learning objectives (Kato, 2010).

Research goal

The aim of this research was to develop a computer game to teach immunology concepts and facts to students in an integrated fashion by incorporating theory, stimulating visuals and a hands-on approach. Our approach should promote learning for the future both in its methods of delivery and by appealing to a large student audience, being based around easily recognizable components which are fundamentally user friendly, yet achieve the desired learning outcomes.

Game prototype design and implementation

The prototype game that we have developed consists of three sequential levels, each of which introduces several new immunological concepts. The division of the material between levels reflects the order in which these events occur during the immunological response to an infection occurring in the body, thereby reinforcing students' understanding of the chronology of these events. Each level involves interactive gameplay inspired by some fundamental aspects of the immunological system – this is augmented by further detail supplied by pop-up notes and animations that occur in response to key events in the game.

Level 1 (Figure 1) covers the role of neutrophils in the initial response to an infection. The level uses Pac-Man™ inspired gameplay, with the student controlling a neutrophil as it moves through a maze-like environment of epithelial cells, consuming pathogenic (disease-causing) bacteria. The level ends when the neutrophil itself dies after consuming a large number of bacteria.

Level 2 (Figure 1) is based on similar gameplay to the first level, but covers content related to macrophages. It introduces the concept of Natural Killer cells, and the role that they play in increasing the activity of other macrophages – this is introduced via text notes, and then emphasized through gameplay by increasing the speed of the player-controlled macrophage when it encounters a Natural Killer cell.

Level 3 (Figure 1) covers the concept of macrophage rolling, and macrophage binding with selectins and integrins. This level uses a different gameplay approach based around a pseudo-3D visualization of the bloodstream. The student must steer the macrophage towards particular molecules (selectins) in order to interact and slow its progress before stopping completely by binding to a different molecule (integrin). This must be done whilst avoiding red blood cells, contact with which disrupts these bonding interactions and interfere with the slowing process. This game ends when players successfully slow the macrophage to the point that it can escape from the bloodstream.

Figure 1: Neutrophil response maze structure, protagonist and enemies (left), and the 'macrophage rolling' game (right).

The game prototype was implemented using Adobe Flash software. This enabled the production of script and animation assets to be performed in parallel, thereby shortening the development lifecycle. In addition the cross-platform, widely-adopted nature of Flash and the ability to embed it within a website maximizes the potential range of situations in which the game can be accessed, thereby increasing the likelihood of its uptake.

Methodology

To test the effectiveness of the prototype computer game, the research team recruited volunteer subjects from a second year undergraduate course in Immunology. Students were given a lecture on the 'innate immune system' that covered topics contained within the computer game. This group of students was then randomly divided into 2 subpopulations – those who would engage in 30 minutes of private study (tutorial) from the textbook, and those who would have 30 minutes to play the computer game. To ascertain the baseline knowledge prior to private study and the computer game session, both groups were asked to fill in a basic survey of knowledge with a series of short answer format questions based on content from the lecture. This same basic survey was repeated immediately after the conclusion of the private study (tutorial) and computer game session. The course coordinator graded the survey responses and student performance was ranked based on total score. The research team also examined volunteer groups of students without previous biological education: one group of first year biomedical science students who had not studied immunology, and one group of computer science students with no background in tertiary biology. These cohorts were used to judge the effectiveness of teaching difficult immunological concepts to those with minimal or no biological science background as a preliminary step towards modifying the material for secondary school audiences. The study design is shown in Figure 2.

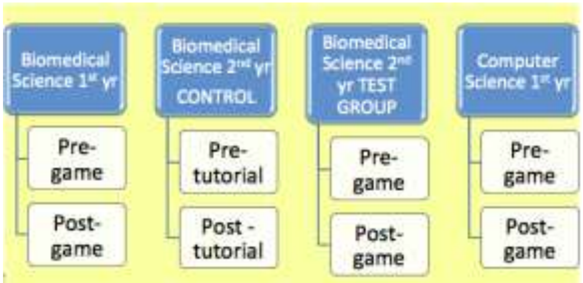

Figure 2: Study design flow chart

Discussion of findings

In the cohort of second year students studying immunology we observed equal increases in knowledge gained after playing the computer game as we did for private study (Figure 3). The increase in knowledge in each group was significantly greater than that obtained after lecture alone. We believe that this is an important finding as it provides statistical evidence for the effectiveness and further exploration for the efficient use and development of computer gaming in tertiary learning environments. It also indicates the ease in which carefully crafted and designed games-based learning tools can be incorporated into education to assist with tutorial and home-based supplementary study in an efficient manner (Ambrosio, 2012). The benefits that such an approach and extended learning environment can have to private learning could be immense as they provide a kinesthetic approach as well as the more traditional text-based and visual learning approaches, appealing to a wider variety of learners in an innovative way. Furthermore, we observed significant increases in knowledge in pre-game and post-game settings for the cohorts without the exposure to immunology lecture material. The capacity for the game to teach basic immunological principles to learners without a background in tertiary biological sciences is clear; this work paves the way for the introduction of the game into secondary schools to teach and promote the study of sciences at university.

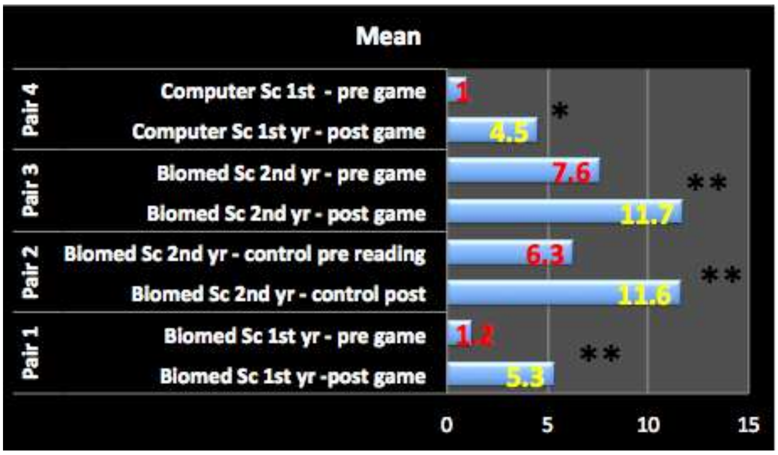

Figure 3: Mean student scores: pre-game and post-game scores (Pairs 1, 3 and 4), and control pre-reading and post-reading scores (Pair 2); * indicates significance at *p*<0.05, ** indicates significance at *p*<0.01.

Further dissection of the results revealed interesting correlations between the use of private study (tutorial) versus computer game learning style tools and their impact on test scores. There were very similar, strong correlations between the use of private study/computer game use and the improvement in test score evident in this study (Table 1). Conversely, only moderate correlations were observed between game use and improved test score in the computer science and 1st year biomedical science cohorts who lacked significant underlying biological knowledge. These correlations reinforce the notion that the use of the computer game in this study has contributed to improved test score, equivalent to the contribution of private study from the prescribed text-book.

Table 1: Correlation scores reflecting equivalent contribution of private study/computer game play to improved post-game test score

Cohort	Correlation
Biomedical Science 1st year	0.56
Computer science 1st year	0.44
Biomedical science 2nd year control group	0.90
Biomedical Science 2nd year game group	0.93

Limitations & conclusion

The key limitation in this study is a number of participants. We recognize the limited data obtained from the present study and consider this a pilot study for the future development of the game and research into its effectiveness. Population numbers in any given study group was not greater than 8 participants, and was just 5 participants for the targeted 2nd year undergraduate cohort. We will continue to research the effectiveness of the game as a study aid as new cohorts of students undertake the biomedical science program in an effort to boost the statistical significance of our findings. Despite these limitations we strongly advocate for the continual development, design and assessment of games-based approaches to teaching science related topics through all levels of education. We believe that innovative learning and teaching pedagogy approaches need to be relevant and add value to current student cohorts in an effort to build capacity learning opportunities in this health domain. With a national shortage of science-based healthcare professionals, educators need to be more innovative to attract potential secondary school leavers into this field and maintain their interest by further enhancing their learning capabilities within the higher education sector. A new era of learners should demand a blended new innovative approach to enhance the learning and teaching experiences for all future generations.

Acknowledgments

We thank the Telematics Trust of Victoria for funding the development of the prototype computer game and we are grateful to Scott Johnson and Jocea Sallai for construction of the prototype game.

Authentic learning and Web 2.0 – Completing the equation

Vickel Narayan
Centre for Learning and Teaching (CfLAT)
Auckland University of Technology

Chris Lovegrove
Faculty of Transport and Built Environment
Unitec Institute of Technology

While new technologies are explored as a way of creating authentic learning environments for the learner, for example, creating simulations and web-quest, there is little research on the potential use and application of Web 2.0 tools and technologies in enhancing the learning process in an authentic environment. The participatory nature of Web 2.0 tools, amplified by portable mobile technologies, empowers users by enabling the ability to create, co-create, collaborate and communicate, and has the potential to bridge the gap between authentic learning activities and the learner's interaction with the surroundings (context), self (cognitive and meta-cognitive) and peers. This paper outlines the findings of a one-year-long project where authentic learning formed the underlining platform for learning and teaching in a Boat Building course (Certificate in Applied Technology, Level 4) where Web 2.0 tools and learner owned mobile devices were integrated to enhance the learning process.

Keywords: Authentic learning, Web 2.0, social constructivism, student-centred, pedagogy 2.0, portable mobile devices

Background

The Certificate in Applied Technology (Boat Building, Levels 3 and 4) courses at Unitec Institute of Technology were always taught within an authentic context. The authenticity of the tasks students completed and the context within which it happened were driven by two main student learning activities over two semesters. In this year-long course, the students build (i) a small dinghy in the first semester and (ii) a medium sized racing yacht in the second semester. While the authentic learning environment offered plenty of opportunity for learner-centred learning and teaching, the role of the lecturer and students in the process however proved to be the main obstacle in capitalising on the opportunities that arose.
The lecturer played the role of spoon-feeding the students at every step of the process with information and knowledge he thought was appropriate for his learners to have prior to starting any stage of boat construction. While the authentic learning environment was productive, the apparent "transfer of knowledge" model limited student ownership of boat building and their own learning.
The students in the course submitted a portfolio at the end of every semester that outlined the boat building techniques learnt, elements of teamwork and collaboration, and their weekly reflections. The students used a book to keep a log of the events that transpired during each day of the week. The lecturer assessed this logbook at the end of the semester and the peers in the class provided feedback on the collaborative aspect in the course by filling out a peer assessment form. An outline of the old marking schedule is available at: https://docs.google.com/document/d/1O-cpTCfPwwP16C7o0M5apyCntOxKAWwFKgKV6o7snOE/edit

Literature

> Authentic learning typically focuses on real-world, complex problems and their solutions, using role-playing exercises, problem-based activities, case studies, and participation in virtual communities of practice (Lombardi & Oblinger, 2007, p. 2).

In a teacher-centred environment, activities students undertake as a part of their learning are seen as a way to clarify and practice, with an assumption that if these activities are designed and structured well, effective learning will take place. They are designed to measure competence and to assess whether the student has gained the skills and content knowledge, or not (Reeves, Herrington, & Oliver, 2002). In a student-centred constructivist-learning environment, learning activities are designed to allow students to plan a project or task from start to finish. The course is not designed in a linear fashion, rather it is taught to students in small 'chunks' to 'give a purpose and meaning to the learning that will occur without predetermining and limiting the scope and sequence of the inquiry' (Reeves, et al., 2002, p. 563). Because the learner is taking charge of their own learning, the role of the teacher in providing feedback and guidance in the process is extremely important. Even more important is the collaboration between students to make the task achievable and engaging (A. Herrington & Herrington, 2007; J. Herrington, 2006; Reeves, et al., 2002). Herrington (2006) espouses that authentic learning is at the heart of situated learning (Lave & Wenger, 1991) and that it revolves around collaborative social learning thus making interaction between the learners a critical element in the process. Herrington (2006), in outlining the characteristics of authentic learning states,

> problems are set within an authentic and realistic context, they are ill- defined and complex, they require a significant investment of time and intellectual resources, problems require examination from multiple perspectives, they require collaboration and reflection, they are integrated with assessment, and supported by scaffolding (p. 5).

Web 2.0 is defined as:

> a second generation, or more personalised, communicative form of the world wide web that emphasises active participation, connectivity, collaboration, and sharing of knowledge and ideas among users (McLoughlin & Lee, 2007, p. 665).

According to Churchill (2005), 'technology amplifies our intellectual and physical capacity' (p. 347) and thus has the potential to support higher order learning. However, technology is being used to recreate the same pedagogical practices present in current classrooms that date back to the nineteenth century (J. Herrington & Kervin, 2007; McLoughlin & Lee, 2007). The transmission of content (using PowerPoint, PDF and Word files) to students is seen as effective practice for emerging technologies. Herrington (2006) states that rather than using new technologies as a medium to transfer content to the students, 'technologies can be used by students as intellectual partners, and as tools to analyze and interpret their understanding' (p. 219). While new technologies are explored as a way of creating authentic learning environments for the learner, for example, creating simulations and web-quest, there seems to be little research on the potential use and application of Web 2.0 tools in enhancing the learning process in an authentic environment (A. Herrington & Herrington, 2007). The participatory nature of Web 2.0 tools, means user empowerment such as the ability to create, collaborate and communicate has the potential to bridge the gap between the authentic learning activity and the learners' interaction with the surround (context), self (cognitive and meta-cognitive) and peers (Dunlap & Lowenthal, 2010). Vygotsky (1978, 1986) espoused the zone of proximal development (ZPD), where he outlined the development the learner can undergo by him/herself and further development is made possible by providing appropriate scaffolding by a person with higher expertise. In a collaborative environment augmented by Web 2.0 tools, the scaffolding in the ZPD can be provided by peers in class, the teacher, or any other expert from around the world (Borthick, Jones, & Wakai, 2003). Borthink and Co (2003) suggests that peers working collaboratively on a problem are able to create a higher level of intelligence in the process. The Web 2.0 tools can amplify the rate of interaction between the learners and thus the enhance exchange of ideas. In the process of exploring each others' ideas, exchanging tacit knowledge (know-how) and explicit (know-what) (Brown, 2006), and by comparing experiences and disputing the differences between them, the learners create higher levels of meaning and understanding that benefits the ZPD of all involved in the process (Borthick, et al., 2003; Hansen, Dirckinck-Holmfeld, Lewis, & Rigelj, 1999).

Design

The design of the project took into consideration the context in which the learning was already situated. The students over the duration of this one-year-long course were to build two boats. In the first semester, the task was to build a small dinghy and in the second semester a racing yacht. In other words, the learning was structured around students completing authentic learning tasks such as planning and building boats, and working in teams throughout the course, with access to experts in the field for advice and support. While the course itself and learning were underpinned by appropriate pedagogies, the learning process and facilitation however were embedded in traditional teaching practices, hence negating the benefits of authentic learning. The design of the project (Figure 1) aimed at shifting the facilitation towards learner-centred approaches through the use of learning technologies situated within the authentic learning tasks of building boats.

The researcher started a collaborative project with the lecturer teaching the course in the second semester of 2010. By negotiation, a Netbook computer was made a minimum course requirement; students were given a choice of buying any other device as long as it had a camera and was WiFi capable. The students who could not afford to buy a Netbook computer or similar due to financial difficulties had the option of borrowing a device for the duration of the course from the institutional pool.

The students in the class were introduced to Google applications, mainly YouTube, Picasa, Google Docs and Blogger. As a part of course orientation, students were taken through the steps of creating a Google account and setting up a blog using Blogger. All the students in the class were provided hands-on tutorials on how to use these tools on the computer and on their mobile devices. A departmental flip camera was also made available to the students for use in class when needed.

To improve learner engagement in the learning process and to transform the learner role into being a 'content creator' from a 'content consumer', learner-generated content was made an explicit course outcome. The students were to use their blog as an eportfolio for the course to collate all the digital artefacts (pictures, videos, posts and conversations) they had created in the process. It was envisaged the ecology of tools surrounding the creation of an eportfolio, for example, Blogger, YouTube, Picasa and Google Docs would help create a dynamic and an interactive platform for the lecturer and other peers in class. The lecturer also established a blog to drive the learning, model effective practice and provide feedback to the students by posting comments on the student blogs.

Methodology

A participatory action research (PAR) method was used in this study (Kemmis & McTaggart, 1988). The participatory (collaborative and communicative) nature (McNiff, 1988) of PAR helped build a community with the students and staff over the duration of the course. This allowed the researcher to provide pedagogical and technological support to the lecturer within the context of the study and technological support to all the students on a weekly basis. The participatory nature of the research also afforded the researcher to collect relevant data on a weekly basis and also provided an opportunity to consider the feedback given by the lecturer and students on elements that needed improvement. The feedback from the students, and the lecturer's own reflections, informed the approach for the following week as part of an action research cycle. The students and the lecturer signed a consent form to participate in this research. The institute's research committee granted ethics approval for this research.

Data collection

The data for the study was collected via a voluntary pre-project survey. Data was also elicited from student and staff blogs. The researcher also kept a log of feedback and observations from the weekly meetings with the students and staff for the duration of the study. A post-project focus group was held with voluntary students and at the end of the course an interview was conducted with the teaching staff. The pre-project survey was administered to ascertain the types of devices the students had access to, the web tools students had used and what they were using them for.

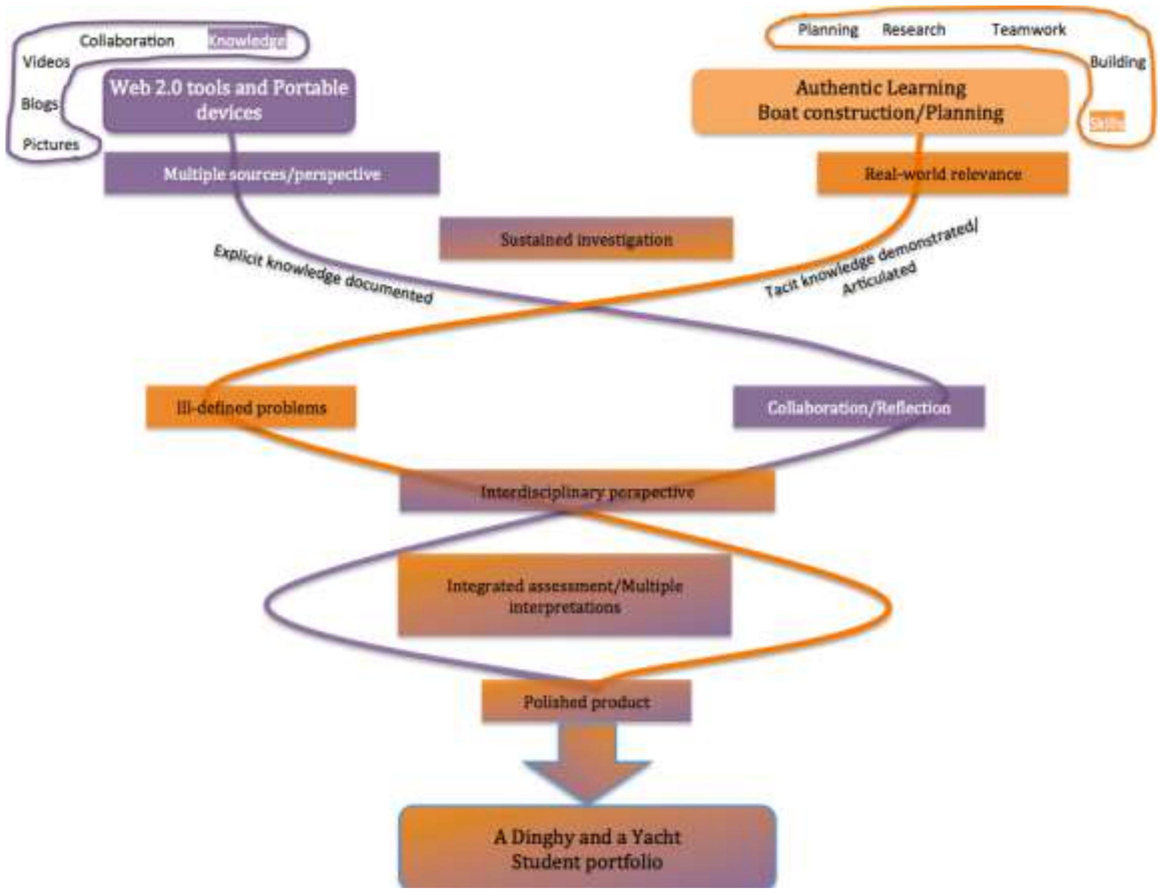

Figure 1: Concept map of the use of Web 2.0 tools in Authentic learning

Results

Pre Project Survey

A voluntary pre-project survey in semester one elicited data from the students on the type of technology and web tools they had access to and had used prior to starting the course. A total of ten students (n=19) participated in the survey. Figure 2 provides an overview of the types of web tools students had used. While the students had accessed a variety of tools, the use was mainly driven by the need to access data. The students were mainly content consumers, not producers. For example, only two students had used an online document editing service while almost all students who took part indicated that they read a blog or viewed a YouTube video. Only one student out of the participating 10 had an active blog. All students in the class (including those who did not take part in the pre-project survey) indicated they had a laptop with wireless capability and three indicated they had a Smartphone.

Student blogs and observations

Student blogs – student-generated content

In the length of the course, in excess of 81 videos were created by all the students in the class (n=19). This number excludes videos that were kept private or where students had disenabled embedding. The playlist of all public or accessible videos created by the students is accessible at:

http://www.youtube.com/playlist?list=PLE62CEEE97758F29E**.** While students used videos frequently to enhance their portfolios, pictures were more common. Almost every single student blog post had made use of pictures to inform the writing process. An average of 23 blog posts were made by the remaining fifteen students of the nineteen that started the course; the highest being forty blog posts and the lowest, seven. The class blog bundle can be accessed here:

http://www.google.co.nz/reader/bundle/user%2F04444936209981325189%2Fbundle%2FMarine_2010**.**

The videos created by the students documented the process of boat building for both of the boats. Upon analysis, the videos could be broadly categorised in four groups, (i) brainstorming and planning, (ii) documentary and evidence, (iii) reflection and (iv) mixing and remixing of existing videos. The videos under the brainstorming and planning category outlined collaboration between students. The collaboration included brainstorming and conversations between groups and individuals, in order to validate and plan for the task ahead, in the presence of the lecturer for feedback and guidance. The documentary and evidence category includes videos that captured footage of students discussing the agreed ideas and techniques and then applying them to complete a task. The reflective category captured the outcome of the processes and the reflections on what went according to plan and what processes needed improvement. The mixing and remixing category is where the student(s) edited multiple videos to tell a story for learning purposes. These videos, when used by the students to compose blog posts, were complimented by an in-depth narration of the processes and outcomes. At times, when appropriate, the students also used pictures to inform the narrative passage and process outcomes.

Researcher observations

To begin with, the students were skeptical of the approach even when the rationale behind the design was explained. Some students voiced their concern that building a boat and gaining that knowledge was their priority, not blogging. However, after a couple of weeks having used the tools in the process the students started to see the value. An early observation in the class was the early shift in preferred choice of device for use in class from a laptop to student owned mobile devices. Over the duration of the course the number of smart devices (tablets and Smartphones) slowly grew to a point where almost every student had one. They were frequently using these devices to capture pictures, videos and to upload them to appropriate hosting services such as YouTube and Picasa. The students preferred to work on their blogs in their own time, mostly overnight and at home.

The students seemed highly motivated and engaged in the process, taking control of the situation when needed, collectively coming up with solutions, supporting each other and taking control of the learning space. For brainstorming and planning sessions, the students took charge of the blackboard, pinned pieces of paper on tabletops for drawing and made use of the lecturer's computer while searching for information and resources. Some advanced learners mentored and guided the students who needed help. One advanced learner created a set of instructional videos and uploaded them on his blog as a scaffold for other students who needed help with computer drawing. Almost every student's blog had a unique feel and look to it. The students customised their blogs with pictures (mostly boats), added additional structure to their blog to make posts more visible and easier to access, and kept their profiles updated. While the blog posts did not trigger a lot of conversations online (commenting on blog posts), they did create lots of face-to-face discussions and conversations in class. The atmosphere in the class was one of openness and collaboration. The students welcomed questions from others and were willing to help peers when approached.

The lecturer initially needed guidance and support to make the transition and to make sense of the Web 2.0 tools. However, after four weeks of being engaged in the project, he started to see results and began to actively seek resources and information on effective use of Web 2.0 tools in learning and underpinning pedagogies. As a result, he explored and blogged about social constructivism, authentic learning and Laurrilard's conversational model (Laurillard, 2007) for learning and teaching. The lecturer's role in the process was observed to have changed to a facilitator and a guide that students called up when they needed advice. The lecturer was observed to have moved from computer-based applications to cloud-based collaborative services.

Student focus group

The feedback from the focus group with five volunteering students indicated that the use of Web 2.0 tools in the learning process benefitted them in various ways. According to the students in the class, the integration of Web 2.0 tools and mobile technologies did not pose a steep learning curve. They were already using the tools but lacked focus for use in their learning. The students also highlighted the fact that the approach certainly provided them with flexibility:

> ….. the concept of Web 2.0 initially sounded complicated or specialized however this new educational approach actually uses daily computer software and program, online applications and resources, and other IT technologies we use everyday, such as 3G network on our mobile, recording video and taking pictures with camera or smart phone, etc. (Student W)

The students also commented that the design of the course and use of the Web 2.0 tools made them more responsible for their own learning. It provided them with the opportunity to 'write down what they had done, what they were thinking, and what kind of help they needed' (Student T). The setup created a collaborative environment where peers in class could read a blog post and comment on it. At the same time, it provided the lecturer with a mechanism to assess the students' current knowledge and provide additional support and guidance when needed. The combined effect of Web 2.0 tools and mobile devices provided students with an opportunity to access information, and to network with each other at any time. This also provided continuous connectedness and an opportunity to create a context for their own learning, because learning was no longer situated within the four walls of the classroom:

> … it improved communication between students and tutors with little or no limitation to time and place. When compared with face-to-face meeting and communication, students and tutors now can communicate online. You can post your ideas, thoughts, suggestions or comments at anytime, anywhere. You do not have to be in the workshop in order to discuss with your peers and the tutor. (Student C)
>
> The tutor was able see how each student was doing throughout the course. This gave the tutor an opportunity to make more comprehensive and flexible assessment of the student on the basis of their learning and not only on the basis of the final outcome. (Student W)

When the students were asked to reflect on their experience on the course and if it was motivating and engaging they stated that when compared to other courses they had enrolled in, their personal experience and observations of the peers was that they drove the learning as the learner. Because of this they were willing to put in the extra effort when needed.

> I think my colleagues in class and I myself were motivated. Well for me as a student, if your assessment and portfolio will be based on what you put on your blog it makes you pay more attention to your daily study. Moreover, you can also help other students if they posted any questions on their blog and made comments on your work. And remember, other students can do the same for you. (Student T)

The students also reflected on the artefacts they had created, the process and how it helped them and peers in class. For them it was a collection of resources that they could refer to when looking for information but to also use it for reflecting on their role in the process 'you can log what you are doing and you can go back and look at yourself' (Student C). The collection of artefacts also became a scaffold for other students who needed help 'And it kept helping not just me but other people as well and vice versa' (Student Y). A collection of student reflections is accessible at: http://www.youtube.com/watch?v=oqo3lx0zAd0.

Staff Interview

The lecturer, reflecting on his journey argued his role in the process and agreed that feeding information to the students was not an effective pedagogical practice in an authentic learning environment. When questioned what had changed when compared to the old setup, he stated:

> Probably me more than anything, I am more inclined towards student-centred learning rather than teacher-centred teaching as before. I am a learner with my students and where possible I try and model the use of Web 2.0 tools for learning.
>
> During this time I was transforming myself, with the aid of my students and the support staff. The transformation was from being an objectivist to becoming a constructivist. As I read papers and books on journeys others had taken along this path, I resonated them. I really enjoy conversations with students and in most cases the topics are in context with learning, so, when I came across Diana Laurillard's conversational model, the lights turned on even more. This pedagogical approach was to become my main model for teaching/learning.

The lecturer reflects on the impact this change has had on student learning:

> The students took more responsibility for their learning in the process meaning they were responsible for the quantity and quality of the output for themselves and others in class.

According to the lecturer, the students were more communicative in the course and they asked more questions when compared with other times he had taught this course. The students also demanded help when they needed it. "I think they asked a lot more questions and demanded help from me right then.' The Web 2.0 tools enabled student-generated content and allowed the lecturer to work with students at a deeper level:

> The student content enabled me to see the things they were working on. In the past, this was like a concept in the students' brain. Before, I was not able to see what the students were thinking about but now I can watch their videos, read their blogs, look at their reflections and comments and this gives me an idea for where the student is. I can now support the student in the process by making a comment on their blog or discussing it with them in class.

When asked about what he had observed with the students in the class with regards to student portfolio and student-generated content, he reflected;

> It was exciting for them because it is them, it is theirs. In the past we used to give them workbooks and it was all ours. I could see how boring it was for the students. The portfolio is theirs and they are putting a lot more into it, a lot more energy and a lot more emotion. They had a sense of ownership over it because they knew they were going out of here with it. It gave them a sense of pride and confidence. I could sense that they were not interested in their grades so much as they were more interested in what they had created and what they owned.

The content created by the students helped almost every time. It encouraged collaboration and reflection. The video and pictures taken by the students in the process were uploaded and shared with others in the class. Other students made use of the same resources, however they used it to compare and reflect on their own learning. This gave the students an opportunity to improve on their understanding and knowledge. The interview video is accessible on YouTube at http://www.youtube.com/watch?v=qoJEggkvygw&NR=1

Discussion

Learner-driven scaffolding for enhanced learning

The videos and pictures taken by students, coupled with reflective blog posts and other student-generated content, formed the base for embedded assessment that effectively took the form of an eportfolio. In order for the learner to develop, scaffold within the learners ZPD is seen as a critical ingredient. In this study, the student-generated artefacts (videos, reflective videos posts, blog and pictures) were found to be effective scaffolds within the ZPD that the students and lecturer found useful. This was not necessarily limited to these artefacts. The conversations that followed online and offline among the students and between the lecturer and students added further benefits. The students who used their own smart devices appreciated the fact that they were able to create a context conducive to their own learning that was further enhanced by connectedness, ubiquitous access and collaboration. While traditional scaffolding methods are seen as the learner seeking help or support from the 'knowledgeable others' (peers, the lecturer or any other expert) in order to grow its own understanding and knowledge. The pedagogical use of Web 2.0 tools and mobile devices in this study provided the students a platform to collectively negotiate ideas and disagreements; in the process creating new understanding and knowledge that benefitted all the participating parties (Borthick, et al., 2003; Brown, 2006; Luckin, 2008). The mixing and re-mixing of videos and pictures by students to suit their needs or the team's need, the reflections in groups and as individuals on a method or process, and collaboration between the students online and offline all resulted in a scaffolding ecology; a learning ecology that was driven and nurtured by the students and benefitted all who participated beyond the limitations of time and geographical location. The teacher in this process acted as a facilitator or a guide, stepping in when requested by the students or when there was a need.

The underpinning Web 2.0 tools and mobile devices that the students used to create, update and maintain their eportfolios encouraged students to articulate their explicit knowledge in relation to the tacit knowledge. The artefacts captured by the students while carrying out a task/activity and uploaded as a blog post along with reflective narrative enabled the students to bridge the two elements 'knowing' and 'doing' which enhanced understanding. This also allowed the teacher an opportunity to continuously assess the understanding and growth of a student. This change outlines the pedagogical transition from assessment of learning to assessment for learning when compared to teaching practice prior to this project.

Authentic learning and Web 2.0

The integration of Web 2.0 tools and mobile devices in this study was observed to have 'gelled' the characteristics of authentic learning. The linkages between the characteristics were enforced by the collaborative, communicative and participatory nature of the Web 2.0 tools. The mobile devices further enhanced the process by enabling learning-generated content, connectedness and ubiquitous access to resources and information. These factors combined gave the students a sense ownership in the process and enabled them to take charge of the process and their own learning.

Prior to this project the students were still engaging in authentic tasks and context, but the learning process and student role were arguably different. More importantly, in the previous model, the context even when it was authentic (students were still building boats) did not ensure effective learning. In this study the teacher's ability to craft the environment to enable student engagement, openness and participation through the use of appropriate tools, was found to be the key.

Conclusion

This study outlines the important relationship between authentic learning, Web 2.0 tools and portable mobile devices. Authentic learning is at the heart of situated learning and Web 2.0 tools and mobile devices enhance the social, participatory and active engagement aspects of the approach. By augmenting the authentic learning environment with Web 2.0 tools and mobile devices, the learning process was enhanced as it gave learners choice and flexibility over their own learning and also acted as a pedagogical change agent. The use of Web 2.0 tools and mobile devices in this project promoted learner-generated content, context and a participatory and collaborative environment that made the core elements of authentic learning function as a single unit, hence the title Authentic learning and Web 2.0 - Completing the equation.

Using Online Environments to Provoke Student-Enquiry

Fiona Nicolson
Macquarie University

Mitch Parsell
Macquarie University

This paper is intended for researchers and practitioners interested in using online environments to provoke student enquiry in any discipline in higher education. Using a Community of Enquiry model that tackles the pedagogical weaknesses in constructivism, we explain why online environments are so effective in engaging students actively in a learning process that meets the requirements of an academic context. From this perspective, we are able to offer concrete advice on how to design an online environment that will provoke student-enquiry. We explain why a social presence is important in the establishment of a Community of Enquiry and we also align particular web technologies to the various stages in the enquiry process and the students' achievement of a unit's learning outcomes. The reader will develop a better understanding of community of enquiry in higher education, and how to use web technologies to provoke enquiry in an online environment.

Keywords: online Community of Enquiry, higher education, constructivism

"Learning for the future" is a refrain that defines the purpose of higher education for most students; higher education institutions prepare students to engage productively in professional work and community service opportunities that presently do not even exist. "Digital media literacy continues its rise in importance as a key skill in every discipline and profession" and constitutes a "top challenge" for tertiary education (Johnson, Adams, & Cummins, 2012, p.3). This is coupled with increasing desire for flexibility in education: "people expect to be able to work, learn and study whenever and wherever they want" (Johnson, Adams, & Cummins, 2012, p.3). Sustainable and pedagogically sound educational models enable the provision of flexible learning environments that both reflect and prepare students for their future professions and community commitment in the digital age. Creating collaborative online communities of enquiry that engage, challenge and support students, is a means of meeting the expectations of students for flexible learning environments, while prioritising the pedagogical requirements of the academic context. This paper explores the practicalities of designing and facilitating an effective online community of enquiry.

The Online Community of Enquiry Model

Enquiry based learning is "a broad spectrum of pedagogical approaches that ground the learning experience in a process of self-directed scholarly investigation and research" (McKinney & Levy, 2006). In online educational research, there is an influential Community of Inquiry (COI) model which "embraces a constructivist orientation in which the emphasis is on how we construct knowledge" (Akyol, Garrison, & Ozden, 2009, p.15). The learners are defined as "collaborative knowledge builders" in their online COI (Akyol, et al., , 2009, p.78). This emphasis on the students' construction of knowledge can be problematic in higher education. In response, we are proposing a new model, the Re-constructivist Online Community of Enquiry (ROCE) that strives to address the pedagogical deficits of the constructivist approach for the higher education learning context. Constructivist online COI tend to focus on the students' generation of meaning and knowledge that is relative to them and their specific learning community rather than relative to the history of ideas in the academic discipline. Re-constructivism reasserts the centrality of the existing, disciplinary body of knowledge and focuses on engaging students in a robust process of presenting and testing knowledge claims within the online community of enquiry.

Similar to other online models, the ROCE enables students (and their teachers) to engage in learning processes that are asynchronous, student-driven and flexible. In order to participate actively in the ROCE, students must be prepared to engage in academic research, communicate their understanding and interpretation of the literature, defend their analysis in an argumentative, evidence-based discourse, reconsider and extend their arguments in the context of the voices in their community and finally produce a knowledge artefact that has been tested by their peers. Having participated effectively in this robust and challenging learning environment, students will have explored the disciplinary content in ways that equip them to progress in their program of study and ultimately enhance their potential to advance research and knowledge in their future professions.

The ROCE model is applicable to any content area and this paper demonstrates how the various stages in the enquiry process can be supported in an online environment. Design, Cognition and Knowledge are the three core elements in the ROCE model - design and cognition drive the pursuit of knowledge. The design of the unit and the learning space enable cognition based on community-led enquiry, which results in knowledge embodied in the community discourse and digital artefacts.

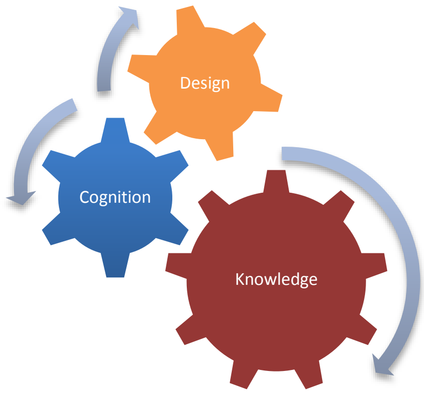

Figure 1: The Re-Constructivist Online Community of Enquiry model

Designing the unit and learning space to provoke enquiry

When implementing the ROCE model, designing the learning space requires considering which technologies can best assist students in participating actively in the enquiry process. The enquiry process involves several levels of understanding such as identifying, describing, comparing, contrasting, explaining causes, analyzing, relating, applying, theorising, generalising, hypothesising and reflecting (Biggs, 2003, p.48). "The ability to carry out a rigorous, systematic process of inquiry and the capacity to apply the skills so acquired in a range of different contexts," is important for students completing their higher education (Brew, 2003, p.16). If students have participated in an enquiry process in which they are required to define and express their own evidence-based voice in their academic community, they will be well equipped to contribute to and ultimately move beyond this community of enquiry. Web technologies such as forums, databases, videos, blogs and wikis can be used at various stages of the enquiry process to support students in their learning and to initiate, sustain and provoke further enquiry. These web technologies are readily available and compatible with most learning management systems. We also suggest including digital artefacts as assessment tasks to ensure a strong alignment between the learning process and measurement of students' achievement of the unit outcomes. As Biggs (2003) argues, "different formats [for assessments] get students doing different things… some being much more aligned to the unit objectives than others"(p172). If students are working online, wiki pages or blogs may be a more appropriate knowledge artefact than the traditional academic essay. In fact, "using Web 2.0 formats …it is possible to assess and support the development of a much wider range of knowledge, skills and attitudes than in the past" (Nicol, 2008).

Establishing Community to facilitate Cognition

Most online communities of enquiry emphasize the need for a strong social presence in order to support students in their academic pursuits. According to Garrison and Arbaugh (2007), the purpose of social presence is "to create the conditions for inquiry and quality interaction… to achieve worthwhile educational goals collaboratively" (p.161). In fact, social presence is an essential precursor to cognitive development because it provides the "groundwork for higher level discourse" (Arbaugh, 2007, p.74). When development is driven by discourse, the community is able to take the required risks and engage fully in their quest for knowledge.

A standard introductory discussion forum can be enhanced by encouraging students to embed short videos of themselves. This video web mail can help establish a sense of community quickly and effectively. Asynchronous video has been found to "deliver the verbal and non-verbal signals necessary in developing positive levels of immediacy and social presence" (Griffiths and Graham, 2009, p.22).

Setting up expectations about the community of enquiry and the students' role in driving the learning process are keys to the success of the pedagogy. It is important to start the unit (after a social presence has been established in a non-threatening way), with a robust discussion encouraging students to embrace the online community as their central enquiry arena and to accept the various technologies that will be used to support the enquiry processes of the community. The voice of the teacher is probably loudest at this time. An informal video recording of the lecturer explaining the rationale of the online community in a relaxed setting can be very useful as students tend to relate well to this more intimate approach. Griffiths and Graham (2009) report "students were able to perceive the instructor and his personality very well through the use of asynchronous video" (p.16). In fact, students reportedly commented that their connection with the instructor was "much more personal, this way, even more so that a face-to-face class usually is" (Griffiths and Graham, 2009, p.16). It would be important to follow up this video presentation with an online discussion in which students can raise and resolve their questions and concerns. Having established an open, trusting community with shared expectations, students are ready to begin the enquiry process.

Triggering the Enquiry Process

At the start, students require triggers to initiate their enquiry process. Most commonly in communities of enquiry these triggers are questions, issues or problems identified by the teacher and/or students for further investigation and research (Arbaugh, 2007). Triggers vary according to the disciplines and the topics being explored. They may include video stimulus, core texts from the literature and/or case studies or experiments. A video case study can be a successful trigger because it provides a common example that the students can discuss in relation to the further academic research that they pursue. The video can introduce some controversy or an issue that requires an argued response from the students and provoke their enquiry process. The video in Figure 1 requires a critical response from students based on an understanding and application of the literature relating to ethics and the media (YouTube, 2011).

Figure 2: Sample of a video that can trigger the enquiry process.

As the students respond to the triggers and engage in the research, a database tool can be useful to record and share the research being undertaken in the enquiry process. As students research the disciplinary literature, they need to record ideas from their preliminary readings, so that they can reflect and build on these ideas and conduct further more defined research as they start to increase their awareness and understanding of the topic. For this purpose, each student could commence a research blog. The blogs should show development of the students' ideas as they work through some of the disciplinary literature. The blogs are the students' means of creating their knowledge claims that will be put to the community for testing and discussion.

Testing Knowledge Claims through Discourse

As students start to develop their knowledge claims, they need a space to "test" (present, defend and extend) these claims. A discussion board is the ideal online space for this testing of claims. Students need to be able to respond easily to each other as they engage in an evidence-based debate and critical dialogue of their peers' contributions. During this time, students will be participating in several different online discussions, they will be defending their own knowledge claims and critiquing the claims of their peers. Students need to provide academically credible evidence in their argumentative discourse and this may include links to various audio-visual materials or websites. Depending on the nature of the discipline, students can include videos taken during practical placements in relevant professional contexts.

The student who is presenting the knowledge claim will lead each discussion. It is their responsibility to ensure the debate progresses constructively. They will synthesize the relevant input from other students and follow up on new literature that is provided by peer critique. Students can also continue to maintain their personal research blogs throughout the enquiry process.

Producing Knowledge Artefacts

Having thoroughly tested their knowledge claims through the discourse of the community discussion, students are able to produce knowledge artefacts. Ideally these will use a digital format that aligns with the online enquiry process that the students have engaged in. They may use a wiki to present their digital essay incorporating links to audio-visual evidence. The wiki can be opened up to the community for more peer editing and commentary as deemed appropriate. The student blogs are also digital artefacts that can be used to evaluate the students' research and their development of knowledge claims to test in the community discourse. These knowledge artefacts can then be evaluated as part of the overall assessment of each student's achievement of the unit outcomes.

Conclusion

The ROCE model is based on the premise that students' learning is enhanced through collaboration and critical discourse with peers. Its design is tailored to the goals and demands of the higher education environment. This is evidenced by its commitment to engaging students directly with the literature of their chosen discipline. The process of enquiry mirrors the process of scholarly endeavour and debate. Students create supportive online communities of enquiry that enable them to challenge themselves and their peers to delve into disciplinary knowledge and emerge with a clear voice that is able to expound the legitimacy and frailty of the various academic positions within the literature. The online environment provides flexible, purpose-built web technologies such as videos, forums, blogs, databases and wikis, which can both support and provoke students to engage in the enquiry process. The ROCE is pedagogically a better fit for the higher education context than the more constructivist models that prioritise the students' construction of knowledge over their engagement with the history of ideas in the academic literature. Overall, the ROCE is an approach that is flexible enough to apply in different disciplines and can be set up in most learning management systems. It offers a sustainable model that will address demands for flexible study environments that develop digital literacy skills (Johnson, Adams, & Cummins, 2012) and as such, constitutes a means for facilitating learning for the future.

Mobilising authentic learning: Understanding the educational affordances of the iPad

James Oldfield
Department of Accounting and Finance
Unitec, New Zealand

Jan Herrington
School of Education
Murdoch University, Australia

A strong body of evidence exists around the power of authentic learning as a pedagogical model to support learning for the future. In recent years, with the increased understanding and focus on authentic learning theory, the educator's toolkit has continued to grow. Mobile technologies have also undergone rapid change during this time, including the emergence of a new category of mobile tablets inspired by the iPad. For teaching and learning to succeed in the future, we cannot afford to ignore technological and pedagogical change. This paper outlines the motivation and plans behind a study to augment the theory of authentic learning and develop a set of mobile authentic learning principles. The study is informed by the theories of authentic learning, cognitive tools and mobile learning supported by the educational affordances of the iPad. Design-based research methodology will be employed to ensure the rigor of the study through two iterations of experimentation with a first year tertiary information systems for business course.

Keywords: mobile learning, authentic learning, cognitive tools, iPads

Introduction

A significant body of evidence exists on the benefits of a constructivist approach to teaching and learning (Bodner, 1986; Duffy & Cunningham, 1996; Gijbels, Watering, Dochy, & Bossche, 2006; Loyens & Gijbels, 2008). Authentic learning is one such learning theory, influenced by a constructivist philosophy. Authentic learning environments are only rarely used in higher education courses, despite the evidence of their capability to promote higher order learning (Lombardi, 2007b).

Technology has significant potential to be an enabler for authentic learning (Lombardi, 2007b), in particular through its use as cognitive tools (Jonassen & Reeves, 2004). Yet, despite a willingness to create more authentic and engaging learning environments for students, there are a number of factors that inhibit the approach in higher education. Pressures to increase class sizes, and teach in tiered lecture theatres, together with restrictive assessment policies (such as mandatory examinations or limitations on group work) pose challenges to teaching in an authentic learning environment. In this paper, we describe the design of a research study into teaching and learning with technology in a business course. The study will use a design-based research method (Reeves, 2006) to investigate a more authentic approach to teaching business using iPads as cognitive tools.

The traditional business course structure provides challenges to maintaining a case for the duration of the course. Semester long (16 week) courses are often taught in conjunction with other courses, splitting a student's time and attention across several disconnected discipline areas. Students may only see the lecturer or tutor for a few short hours a week, making it difficult for them to be immersed in the learning experience. Perreault (1999) suggests that authentic activities take much more time than more traditional learning exercises. If this time is unavailable within the set class structure, then an additional mechanism is needed to support these authentic activities beyond the classroom. As suggested by Lombardi (2007b), technology has the potential to greatly expand our range of authentic activities in the classroom, and one could argue, beyond it. Mobile technology in particular could be used as a way of bridging the gap between formal class sessions and sustained and engaged learning (Barbosa & Geyer, 2005).

In 2010, the arrival of the iPad was heralded with much interest and excitement, particularly be educators who could see its potential for use in student learning. Twenty five million units of this immensely popular consumer device sold within the first fourteen months (Jobs, 2011). It has reimagined and revitalized the market for tablet computers, effecting a reduction in demand for netbook and laptop computers. Due to its success, competitors have increasingly shifted their focus toward their own tablet offerings, and now, a number of high quality and relatively low cost tablet alternatives available. Such tablet computers have potential affordances for education that have not been explored in any great depth to date, especially in regard to their pedagogical advantages. The study described in this paper will explore current theory and practice, emerging developments and technological capabilities to investigate the pedagogical use of tablet computers, and develop a model for their use in supporting authentic learning environments.

Authentic learning

The age-old method of apprenticeship training has inspired the creation of educational pedagogies that value the importance on the context of learning. Collins (1991) suggested that in order for learning to be meaningful, it should be embedded in the same context that it will be used in later life. This is a fundamental principle of the theory of *situated cognition* or *situated learning* (Brown, Collins, & Duguid, 1989), a theory that has greatly informed the theory of *authentic learning*. Lombardi (2007a) emphasises the importance of higher order thinking and analysis that is afforded in authentic learning:

> To be competitive in a global job market, today's students must become comfortable with the complexities of ill-defined real-world problems. The greater their exposure to authentic disciplinary communities, the better prepared they will be "to deal with ambiguity" and put into practice the kind of "higher order analysis and complex communication" required of them as professionals. (p. 10)

Herrington and Oliver (cf. Herrington, Reeves, & Oliver, 2010) propose a list of nine key elements that characterise an optimal authentic learning experience. Authentic learning environments:
1. Provide authentic contexts that reflect the way the knowledge will be used in real life
2. Provide authentic activities
3. Provide access to expert performances and the modeling of processes
4. Provide multiple roles and perspectives
5. Support collaborative construction of knowledge
6. Promote reflection to enable abstractions to be formed
7. Promote articulation to enable tacit knowledge to be made explicit
8. Provide coaching and scaffolding by the teacher at critical times
9. Provide for authentic assessment of learning within the tasks (p. 18).

Such research has provided much insight into how technology can be used to promote authentic learning in higher education. However, further in-depth exploration is needed to explore how technology can be used as a cognitive tool to solve problems and create genuine artefacts within these environments.

Cognitive tools

Also referred to as *cognitive technologies* (Pea, 1985), t*echnologies of the mind* (Saloman, Perkins, & Globerson, 1991), and *mindtools* (Jonassen, 2000), *cognitive tools* have been described by Jonassen and Reeves (2004) as "technologies, tangible or intangible, that enhance the cognitive powers of human beings during thinking, problem-solving, and learning" (p. 1). Computers, smartphones, mobile tablets and the software applications they support, can all be used as cognitive tools. Viewing these devices as cognitive tools shifts the focus of the devices from being a medium for the delivery of content to a platform for the creation of knowledge. The student as the designer replaces the role of the instructional designer. The student uses the technology to access, interpret, organize, analyse and present knowledge to others.

Jonassen et al. (1998) propose that mindtools have the capability to engage learners in critical, higher-order thinking about content because:
1. The learners are the designers
2. The focus is on knowledge construction, not reproduction
3. Learning is in partnership with technology
4. They are unintelligent tools, relying on the learner to provide the intelligence
5. They distribute the cognitive processing
6. They are cost and effort beneficial. (p. 13)

Most research into cognitive tools to date has focused on computers rather than more recent mobile devices. With the arrival of the iPad in 2010, the world of mobile devices has undergone significant change. Many mobile devices now have similar processing capabilities and functionality to modern laptops and desktops, and they could be employed as powerful cognitive tools. This increased functionality could be used to support authentic learning, as described in the next section.

Mobile learning

An ever-widening body of research exists in the area of mobile learning (also known as mLearning). As with most theoretical constructs, there are many different variations on what mLearning is and what its most critical aspects are. mLearning provides the learner with an increased ability to take their learning environment with them as they move (Barbosa & Geyer, 2005). mLearning is said to have two distinct aspects to it: the use of mobile learning devices, and the mobility of the people and the knowledge themselves (Sharples, Taylor, & Vavoula, 2007). Sharples et al. (2007) define mobile learning as: “the processes of coming to know through conversations across multiple contexts amongst people and personal interactive technologies” (p. 225).

Tablet based mobile learning

Recent advances in the world of tablet computing, as illustrated by the popularity of the iPad and other tablet devices, provide some answers and new questions to the field of mLearning. Now in its third generation, the iPad is still by far the leader (in terms of sales numbers) in the global tablet market. Over its three generations, the iPad has matured in terms of features to include two cameras, dual core processing technology, a high-resolution screen and 4G connectivity. Many educational institutions around the world are making use of the iPad through student and staff projects, distribution schemes (the Science Faculty at Adelaide University, for example, where students are provided with an iPad once enrolled) and the informal use of student owned devices.

In a comprehensive study on the use of mobile devices in higher education, Cochrane (2010) proposed five pedagogical considerations or “critical success factors” to mLearning:

1. The level of pedagogical integration of the technology into the course and assessment.
2. The level of lecturer modeling of the pedagogical use of the tools. (I think modelling is right, or did Thom use modeling?
3. The use of regular formative feedback from both lecturers and student peers.
4. Appropriate choice of mobile devices and software.
5. Technological and pedagogical support.

It is clear that tablet computers possess many affordances that could potentially enhance learning. However, as stated by Melhuish and Falloon (2010, p. 13), “A new mobile device might eventually be a catalyst for a sea-change in the way we perceive education, but the urgency and relevance of the learning need should always drive its use”. The theory and literature discussed above in relation to *authentic learning, cognitive tools* and *mobile learning* will provide a theoretical framework for the enquiry.

Theoretical perspectives to frame the study

The proposed research will be informed by principles of learning and theoretical constructs developed in *authentic learning, cognitive tools* and *mobile learning theory*. With technology, they will form a new theory of Authentic Mobile Learning. A conceptual illustration of the study and its related theory is provided in Figure 1.

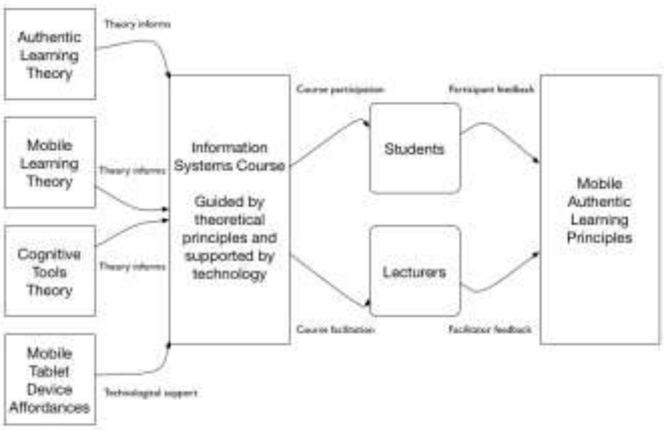

Figure 1 Mobile Authentic Learning Conceptual Framework

A design-based research approach (Reeves, 2006) will be used to develop, iteratively test and improve the design principles in an academically rigorous manner. This project will take place in two iterations over two full semesters with the design principles guiding the design of an introductory *information systems for business* course using the iPad as the cognitive tool of choice.

Investigating new technologies in education contexts is frequently conducted atheoretically, resulting in a focus on the technology itself, rather than as a pedagogical support. This study situates the study of a new and powerful technology (the iPad) within the context of the pedagogical theory of authentic learning, and with the focus on the device as a mobile cognitive tool that provides learning for the future.

Peer review of e learning Initiatives at Charles Darwin University: The DSA project

Margaret Pack
Charles Darwin University

The Diversity and Structural Adjustment Fund (DSA) project at Charles Darwin University, Northern Territory Australia, aims to peer review current teaching and learning practices and resources to evolve recommendations for 'best practice' in e learning. A staged approach over two years was planned to evaluate current practices used in e learning across the University and 'to begin a process of building expertise in flexible and e learning at the discipline level' (Terms of Reference, DSA, Part 3b, v3.0 p2). During 2010-11 I was invited as a consultant on the project to peer review nursing and social work e learning initiatives within the School of Health Sciences. The project, now completed, has had several favourable outcomes. Regular and ongoing quality assurance of e learning sites carried out centrally within the University by the Office of Teaching and Learning has brought greater uniformity through quality assurance processes to the e learning sites across the Faculties. The current version of the internet platform, Blackboard, has been extended and enhanced. Through the purchase of new software, the previous use of WIMBA or the Wireless classroom which posed technical difficulties for the majority of teaching staff, has been replaced by 'Collaborate'. This later software has enabled face to face teaching in tutorials for students in all areas of the University. Other lessons learned include the integration of information about student support services and a more uniform structure to e learning sites as well as the availability technical assistance for academic staff.

Introduction and aims of project

The DSA project was designed to facilitate for Charles Darwin University steps towards best practice delivery with a marked enhancement of teaching and learning quality. In 2008 CDU's teaching and learning performance as measured by recent Learning and Teaching Performance Fund and Institutional Assessment Framework outcomes was below national norms. This performance was strongly related to CDU's rapid transition to a significant external provider in response to demands from both employers and students in the Northern Territory and beyond for the delivery of accredited professional programmes in which there are national skills shortages. These areas include nursing, social work and teaching education. Facilitated by a partnership with Bb Inc., the project aimed to do the following:

- Markedly enhance the teaching and learning performance of CDU;
- Significantly re-position CDU to meet the documented demands of its geographically dispersed, often regionally located unique stakeholder communities (with high representation of mature age, part-time and equity target group students) for high quality flexible provision; and
- Provide stronger service to labour markets in the NT and Australia through improved provision in areas of national priority.

The project had four related and interlinked components which form the chapters of this final report:

- Planning and Strategy Development;
- Optimisation of a Flexible Learning Management System;
- Staff Training and Learning Materials Upgrade; and
- Evaluation of the effectiveness of flexible learning approaches for target equity group students

Towards the end of 2011 the Learnline Steering Group was established which will, amongst other things, oversee the implementation of the recommendations in the above report. The Terms of Reference of the Learnline Steering Group are currently being finalised but the following has been proposed to the Learning and Teaching Committee of the University:

1. To recommend policies and procedures for Learnline.
2. To provide guidance to the PVC LT&CE regarding the learning technologies that should/should not comprise Learnline.
3. To provide guidance regarding upgrades, maintenance and other enhancements to Learnline technologies (including the enablement and disablement of functionalities within the suite of learning technologies).

4. To advise on the establishment and disestablishment of Learnline Roles and associated permissions.
5. To ensure Learnline is aligned to, and supports, CDU's accreditation (HE), registration (VET), review (HE and VET) and CRICOS requirements.
6. To assess the impact of Learnline on learning and teaching and advise accordingly.
7. To assess the implications of learning and teaching policies on Learnline and advise accordingly.
8. To monitor staff and student satisfaction with Learnline and advise accordingly.
9. To make recommendations regarding Learnline training and promotion.
10. To monitor compliance by Schools and VET Divisions with Learnline policies and procedures.

Peer review and upgrade of pedagogic approaches and learning materials in selected programs

The broad aim of this project component was to engage recognised external consultants to review flexible learning practice and resources, and make recommendations for improvement, with a series of eleven discipline groups at CDU and to build expertise in flexible and e-learning at the discipline level.
Peer review of teaching can be described as 'academic colleagues giving and receiving feedback on their teaching practices and its effectiveness in promoting student learning' (Harris, Farell, Bell, Devlin, & James, 2009, p.5). This type of peer review is an invaluable form of evaluation used to make judgements about current practice, and can at the same time be developmental, acting as a means to advance teaching, and as a tool for professional development. That is, it can be used for both formative and summative purposes. Along with student evaluation it helps provide a rich picture of teaching and learning in an organisation, and builds on the expertise already within that organisation. Further, peer review has the potential to develop understanding of the scholarship underlying the design and development of teaching resources (Harris et al, 2009; Taylor & Richardson, 2001; Wood & Friedel, 2008). Peer review for this project will include review of resources as well as teaching approaches, and involve academics from within CDU as well as outside the organisation.
The 11 discipline groups selected account for the majority of CDU's total and flexibly delivered load, and all had significant scope for improvement in the areas of student satisfaction, retention and progress. They were broken into groups of three as follows:

Group 1: Pharmacy, Exercise and Sports Science, Engineering and Information Technology
Group 2: Law, Education, Nursing
Group 3: Business, Social Work, Psychology
Group 4: Creative Arts and Humanities, Environmental Sciences

Each discipline engagement extended over a six-month time frame with the following **anticipated outcomes**:

1. A focus by targeted disciplines at CDU for a period of at least 6 months each, on improving course design and delivery, learning and teaching resources and methods, with special attention to flexible delivery.
2. Engagement of the selected disciplines with consultants who are nationally recognised experts in discipline and elearning/flexible delivery methods.
3. Participation by CDU staff in discipline-based peer review activities, and targeted course design and resource evaluation workshops.
4. Liaison and consultation between the Academic Development Team (ADT), consultants and the disciplines in developing the strategy for the peer review processes and subsequent implementation.
5. Opportunities for CDU staff to learn about their colleagues teaching approaches, share resources, and develop skills in the scholarship of teaching.
6. Summative peer review reports for each discipline by external consultants.
7. Strategies and priorities developed via the peer review process for improving teaching and learning approaches and resources within each of the nominated disciplines at CDU.

For each discipline group the engagement had four **phases**:

- Planning
    - Negotiating and constructing the process for peer review
    - Identifying and contacting possible external peer reviewers in the discipline, and
    - Appointing consultant and negotiating terms of engagement
- Design
    - Consultant's visit to CDU: conducting a needs analysis, document gathering, individual interviews with selected staff, focus group with staff and another with students
    - Remote consultation with expert via phone, email, videoconference as necessary

    - Peer review report compiled by consultant with recommendations for discipline specific educational design enhancements, learning and teaching strategies, additional resources, student support, etc;
- Implementation
    - Implementation and dissemination of recommendations, with ADT and consultant support via group-based and one-on-one support, workshops, mentoring, templates, development of case studies and learning designs, and online and face-to-face delivery of support
    - Workshops delivery by consultant and on-site visit
- Evaluation consisting of a report from the academic consultant and theme leader on outcomes achieved using the following questions as a guide:
    - How effective is the model of engagement and peer review used for the project, as an enterprise wide implementation of new learning and teaching methodologies in Higher Education?
    - What are the enablers for implementation in this context and how can they be utilised so as to embed the new knowledge, skills, attitudes and practices acquired during the project?
    - How can the barriers to embedding sustainable change in flexible learning and teaching (eg technological, pedagogical, organisational and cultural) be overcome at an organisation such as CDU?
    - What are the barriers and enablers to establishing communities of inquiry to support sustainable change and effective peer review activities within the organisation?

The following **deliverables** were expected of the peer review process:

1. A report from each external discipline consultant which includes a review of and recommendations for development of flexible learning and teaching methods, strategies and resources. This will provide a benchmark against which improvements can be measured. This is due, in most cases, about 2 months into the consultation process. Where consultants are contracted to review and support at the unit level only, the report should be short and delivery dates negotiated with the discipline and ADT.
2. A program of peer review activities devised by ADT and each discipline group, and informed by the consultant.
3. A report from ADT on the engagement of each discipline. Due after the four phases are complete: planning, review, design and development and evaluation).
4. A report from either the Head of School or Dean of each discipline. This is due after the four phases are complete.
5. Observable change to learning materials and teaching and learning approaches, following implementation of recommendations from consultants' report.

Organisation wide issues

- The need for reward and recognition of high performing teachers as a means of building teaching and learning capacity across the university.
- Promotion of reflective practice and the scholarship of learning and teaching, leading to amongst other outcomes, publication in high-quality journals. Create the conditions whereby a more scholarly approach to teaching and learning can be fostered, and research is conducted into the CDU student experience.
- The need to create more opportunities for exchange and documentation of best practice exemplars across the University, including an annual learning and teaching conference, and multi-disciplinary best practice approaches for teaching external and blended classes.
- Re-evaluate the issue of pre-requisites and the impact of being 'overly flexible' regarding study plans, at the risk of students missing out of developing key competencies and developing a sound knowledge base in core areas.
- Re-evaluate the practice of posting student evaluations of teaching on the public CDU website. This practice is probably counter-productive and not necessarily supportive of best teaching practice.
- Pedagogical frameworks for working with students of different disciplines be researched (currently a research project is underway). The results of this research then need to be embedded in the pedagogical approaches adopted, and translated into appropriate course materials using on-line and distance/flexible learning.
- Create a culture of teaching and learning innovation through resource allocation to academics.
- Support more flexible use of ICTs by academics, recognising their ability and authority to determine technology requirements.

Theme/discipline issues

- Communicate to students the career relevance of disciplinary knowledge, skills and attitudes.
- Provide resources that support the development and delivery of superior online learning experiences that differentiate CDU positively from other university providers.
- Create exemplars of best practice at the discipline level.
- Continue the practice established in the DSA project of providing time release for designing and developing new units.
- Establish processes by which staff can share and collaborate on the design and development of teaching and learning strategies.
- Assign mentors within each discipline to support new staff, and account for this in teaching workloads.
- Develop processes to assess and develop fair and equitable academic workloads relating to teaching students on and off campus students.
- Map content and assessment within undergraduate degrees. Define and map generic skills, knowledge, learning outcomes, assessment and pedagogic philosophy underpinning 100, 200 and 300 level units.
- Develop introductory online resources for students to orientate them to study and to Learnline, and create standard introductory information for each discipline.
- Model best practice communication styles and skills with distance students, using suitable technologies to establish closer connections with students and encourage persistence and effective study habits.
- Streamline practicum processes, e.g. by forming a working group with multi-disciplinary representatives from a range of disciplines that include practicum: for example pharmacy, education, exercise and sport science and nursing, to determine best practice processes for practicum/placement students at the University.
- Develop consistent policies and guidelines across disciplines regarding a range of academic issues, e.g. addressing student enquiries, plagiarism, late assignments, appeals, moderation of online discussions, and guidelines for effective student study online.

Teaching and learning approaches

- Build a course level approach to issues such as assessment, moderation, assignment turnaround time and feedback, responses to messages in email or on the discussion board, consultation hours etc. (standards, policies and guidelines);
- Develop strategies and resources that allow for the effective teaching of internal and external students in the same cohort using online technologies;
- Move from internal lectures, bolster internal seminars and focus on utilising pedagogical approaches best suited to the online student cohort;
- Use of and reflection on the *Levels of Engaging Students Online*. Staff need to continue to reflect on how to best achieve this type of authentic learning with students whilst managing the balance between student feedback and student engagement in the learning environment;
- Assessment:
    - Adopt assessment practices that effectively utilise the online communication tools.
    - Adopt rubrics as standard practice for assessing students.
    - Use student peer review as a valuable assessment practice in some units.
    - Provide formal mechanisms for students to provide feedback during the semester and feedback on assessment criteria;
- Incorporate strategies that support diversity amongst the student cohort and difference in learning style, and allow for varying levels of technical access, (where not mandated).
- Use strategies that support and encourage ‘community’ online, e.g. a thread on the discussion board for introductions to which the unit coordinator also contributes.
- Focus on first-year units as the foundation for excellence in teaching and learning.
- Provide more professional development and IT support for staff who work on campuses other than Casuarina.
- Sustainability (attainability) needs to be built into Learnline units. There must be a cycle of review and refreshing/updating unit content and online teaching methods built into the unit lifecycle.
- Suitable benchmarking partners should be investigated in order to undertake regular external comparisons between CDU offerings and those of its benchmarking partners.

Technology issues

- Acknowledge and respond to concerns about issues with IT infrastructure which impede easy and innovative response to flexible learning initiatives.
- Re-evaluate the range of tools and the technologies available, over and above those offered via Learnline, encouraging innovation, and including storage capacity for rich-media files generated by staff and students. This includes the greater use of wireless, laptop computers for flexibility.
- Allow for innovation: 'The central policy of locking down information technology is the single largest impediment to CDU competitiveness in teaching and learning for online students.' (Law Peer Review Report)
- Provide continuous, developmental on-going professional development in flexible learning and new technologies.
- Professional development of teaching staff regarding the effective use of web conferencing tools.
- Continue to implement consistency of Learnline templates, based on a discipline model, with design input from specialists in graphic design and educational design.
- Ensure that effective learning experiences are delivered that reflect current online technologies, staff competencies, access to technology support and universal accessibility requirements.
- 'Just-in-time' technical support at the discipline level.
- Provide dedicated Learnline trainers.
- Provide the conditions where innovative use of technology can be supported along with more established CDU practices in the technology.
- Graphic design support and input for all units to improve their aesthetic look and make the online learning environment more competitive with other university online courses (improve page layout, image clarity and sizing, use of fonts etc).
- Consider the impact and use of mobile technologies on the design and delivery of learning activities.
- Embedded technical and educational design support within the themes/Schools to improve quality.
- Explore the options for a centrally managed content management system to store, tag and deliver digital learning objects.
- Trial of new technologies such as e-portfolios (eg Mahara), marking software (eg Remarks).

Student demographics

Given the demographic characteristics of CDU students (the significant majority studying in distance mode , over 25 years of age) an online orientation site has been developed to assist students to make the transition to learning in fleximode. This site, known as Get Learning Online @ CDU, provides students with tips and a series of 10 WebQuest activities to enable them to navigate *Bb* and use it for successful study, communication, collaboration and assessment. The concept, design and activities were evaluated by 10 staff and 34 students and then again further evaluated by 10 students as part of the user acceptance testing for the 9.1 *Bb* upgrade. A total of 92% of the students evaluated the site positively agreeing or strongly agreeing that the site was a useful resource, was appropriate for beginning Learnline users, with the Quest activities helping them to understand how to use Learnline tools and would recommend the site to other students. Qualitative comments also confirmed this positive evaluation: "overall the tutorial was great and would be awesome for new students to engage in".

The introduction of new technologies: collaborate

In November 2011, CDU changed its online classroom system from Wimba to Bb Collaborate. This was in response to increased teaching using online classrooms, facilitated reflection of that practice through the reviews by external consultants documented in the next chapter, and enabled by new product developments in the market. CDU is the first adopter of Collaborate in Australia, but did so confidently having worked with Bb and offshore institutions to ensure robust testing.

There are a number of improvements to the system as a result of the move to Collaborate. Perhaps one of the biggest, most noticeable, differences is the interface. It features a sleeker, modern look and has a number of configurable options to enhance the individual participant experience and control of the session for the moderator. Several windows are movable and re-sizable such as the chat box, audio & video box and the participant view.

Audio and Video functionality has also improved. Moderators can setup a session to allow between 1 and 6 talkers at a time while Wimba did not have a talker limit. This function enables the moderator to control the flow of conversation better. In addition, a session can also allow between 1 and 6 participants to show video at once, while Wimba was limited to only one participant video at a time.

The whiteboard features in Bb Collaborate are also much refined compared to that of Wimba Classroom. The tool allows participants to create text, shapes, built in and customizable clip art, and an animated cursor display. More than that, the whiteboard is object-oriented, which means you can move, resize and manipulate the various objects after they are created.
In Wimba, the configuration wizard must be run outside of the session or prior to joining. In Bb Collaborate, the wizard can be run inside the session at any time. In Bb Collaborate, the audio is buffered and allows participants to "catch up" from a slow or poor connection issue.
In Wimba, the session tends to cater to the lowest common denominator regarding connection speed. In Bb Collaborate, each participant selects their own connection speed and the server pushes content accordingly.
There are also a number of completely new features in Collaborate:

- A web tour which allows the moderator to share specific websites so that participants can follow along;
- File Transfer to upload files and easily push the files to participants during the session;
- Ability to upload video, audio or flash files and push live during the session;
- Ability to create quizzes to push out to participants during the session. Results are graded immediately and can be saved;
- Moderated Chat where participants can chat privately with each other but moderators can view if desired;
- Activity Indicators that show whether someone is typing, talking, annotating, etc;
- Advanced Polling, enabling participants can respond to polls such as Yes/No or A, B, C;
- Plan, a separate application that allows moderators to create session plans ahead of time; and archive

Bb Consulting Services provided extensive training opportunities to CDU staff on Collaborate as well as augmenting training opportunities for Learn 9.1 SP6.
In summary, the DSA project has resulted in a major turnaround in the University's Learning Management System (LMS). Upon commencement of DSA, the LMS was unstable, the cause of significant dissatisfaction among staff (and some students), and not always compatible with teaching and learning requirements. Now the system is stable, favoured by staff and students, and capable of not only meeting but also expanding our learner engagement needs.

Challenges

The main barriers to engagement of staff in supporting activities related to fear and perceived lack of control over the teaching and learning environment when face to face delivery moves online. This was coupled by the perceived dividing line between the need to teach both internal and external students and difficulty in perceiving how to do both together without disadvantaging one or the other.

The findings from these consultations were fed into a formal needs-analysis process facilitated by two Bb consultants resulting from focus group meetings with around 20 central support and 30 academic staff and produced an overall e-learning training plan for CDU.

Their recommendations addressed the following:

- Faculty/Academic Training Strategies:
    - increase professional development for Bb trainers and support staff
    - establish quality standards for course design and facilitation
    - expand training materials and training opportunities for academics
    - provide faculty training incentives
    - form a Bb liaison network.

- Faculty/Academic and Student Support Strategies:
    - structure a cohesive academic technologies training and support team
    - add Bb-specific help desk personnel to the existing help desk team
    - create a knowledge base to provide students and academics a "one-stop" solution to questions.

Outcome of the peer review process: observable change

In all theme areas there was observable change, although this varied according to staff readiness to change themselves, or their approaches to learning and teaching or adopt new technologies. Staff workloads and continual staff turnover are factors that continue impact on the sustainability of any changes made and the opportunity to embed and systemise changes. Nonetheless, there has been observable change in:

- the navigation and structure of Learnline sites;
- staff awareness of the potential of Learnline to be more than a repository for content;
- the approach of some staff to their communication with distance students, so as to better engage students, to support and facilitate learning, and retain students;
- more effective and informed use and evaluation of technology;
- choice of assessment and activities, showing in some areas improved constructive alignment of learning outcomes, activities and assessments;
- expression of learning outcomes, which more precisely indicate what it is that academics expect students to do at the various undergraduate levels; and
- greater awareness of the needs of distance and online students, in terms of support and engagement.

Reponses from theme leaders or Heads of School indicate that the majority of staff were positive about the peer review and consultancy experience, although it is clear that staff need much more support in building units in Learnline, in formatting and shaping content and activities so that they better meet best practice guidelines in flexible learning and use of educational media.

The digital tutor: accepting to lose control and make mistakes

Rachel Panckhurst
Praxiling UMR 5267 CNRS &
Université Paul-Valéry Montpellier 3

Pilot studies using online social networks within a French University postgraduate course were conducted over a five-year period in order to explore and evaluate the relative advantages and challenges of such tools for tertiary education. Students were following a curriculum as part of a second-year predominantly off-campus Master's degree. In this paper, after having defined pedagogical *eLearning exchange networks* (*eLEN*s), and how they can be implemented by using *social learning objects*, the latest case study analysis is focused on providing solutions for effective tutoring in the digital era.

Keywords: educational paradigms, social networks, collaborative learning, mediated discourse.

Introduction

Seven pilot studies using online social networking tools within a French University postgraduate course were conducted over a five-year period (2007-2012), in order to explore and evaluate their relative advantages and challenges for tertiary education. Students were enrolled in a second-year Master's degree ("Knowledge Management, training and digital mediation", Linguistics Department, Paul-Valéry Montpellier 3 University: http://www.univ-montp3.fr). The year-long curriculum was predominantly off-campus, with a compulsory one-week intensive on-campus session between semesters (in December or January), and was the first of its kind to be introduced in the French higher education system in 2004.

A collaborative learning environment and an online community were established and students were invited to use them to discuss pedagogical issues related to eLearning practice, and, in the more recent second-generation case studies (Panckhurst & Marsh, 2009), to organise completion of structured role-play projects. Over the five-year period, three different social networking tools were used: Ning (www.ning.com), grou.ps (http://grou.ps) and, most recently, Google+ (https://plus.google.com).

In this paper, after having defined pedagogical *eLearning exchange networks* (*eLEN*, Marsh & Panckhurst, 2007) (§ 1), and how they can be implemented with "social learning objects" (Weller, 2008) (§ 2), the latest case study, which took place from October 2011 to January 2012, is discussed (§ 3) in order to provide insight and sustainable solutions for effective learning and tutoring online (§ 4).

Social networks, pedagogical networks

An *eLearning exchange network* (*eLEN*) corresponds to the idea of formatting online social networks for pedagogical practice (Panckhurst & Marsh, 2011). In order to differentiate clearly between social and pedagogical networks, *Facebook* was excluded from the initial case studies, and *Ning*, which had just developed its public networking system at that time, was chosen not for novelty, but because it already had a French interface in 2007. Private group (and subgroup) networks requiring enrolment could also easily be set up using this tool on the open Web, hence setting aside any institutional VLE/LMS issues (Panckhurst & Marsh, 2008). In the first eLENs, online forums in which students were required to engage and discuss pedagogical issues related to eLearning practice were initiated, and a student-centred 2 or 3-phase period was adopted (Panckhurst & Marsh, 2011):

1. preliminary getting-to-know-each-other phase (initiated and conducted by the tutors);
2. compulsory discussion threads phase (designed and led by individual students with peer-group student participation);
3. an optional final third tutor-led phase.

Even though the initial functioning was highly appreciated by the students, two years down the track, by 2009, a significant shift in student attitude and perceptions of the place and value of eLENs in their learning was noted. With the increase in student private use of such tools as *Facebook* and *Twitter*, it was clear that students began to expect more from a social network being used as a tool for learning.

Imposed projects as social learning objects

The tutors decided to introduce “social learning objects” (Weller, 2008) in order to “facilitate conversation, and thus social interaction” and therefore moved from peer-driven discussion thread moderation to structured imposed role-play projects (the contents of which they hoped would act as ‘social object’ stimulation), accompanied with support information and weblinks, to be completed within a strict timeframe. An initial concern was that this apparently ‘dramatic’ shift in approach could result in a loss of learner independence/autonomy (*cf.* Downes 2008, and his key concepts for network usage: *diversity, autonomy, openness, interaction*). Not so. Students appreciated not wasting organisational time, and yet still feeling they had space to create original and interactive work:

> Paradoxically, I appreciated the fact that the groups were formed authoritatively, because this avoided people aggregating with others sharing similar interests, and we just had to “make do”. (In actual fact, all of the work I was involved with took place in a perfectly calm and respectful atmosphere.) (Student A is also a teacher; author’s translation).

A second issue was related to the concern that students might slip back into a teacher/tutor-centric pattern, regularly requesting advice. This was obviously not a problem either, judging by a clearly identifiable tutor-learner “form of trust”:

> The almost total autonomy we had for completing the activities […] helped us learn how to organise directives in groups, to confront our ideas and our doubts, without having a teacher to guide us. I think that the tutors established a form of trust with the students and this was perceivable in our work outcome. (Student B; Author’s translation).

The role-play imposed projects were divided into four phases:

1. work within imposed sub-group on imposed project (2-week period, in order to read, analyse, share, exchange and compile a preliminary summary on the topic to be submitted to peers and tutors);
2. peer-led online discussion with whole group on same imposed topic (2 weeks);
3. final write-up within sub-group and hand-in (8 days, submitted both to tutors and peers);
4. subsequent peer and auto-evaluation of work submitted.

This organisation was appreciated owing to its diversity:

> Dividing the work into stages means that it’s not a “monotonous” activity amounting to researching and writing-up. The diversity allows us to see the work evolve and means we can adapt to each stage. (Student C; author’s translation).

The final productions used a wide variety of tools (traditional word-processing documents, pdf and html documents, online documents and presentation tools, e.g., Google Documents, Prezi, Opale-Scenari, mindmaps, word clusters, questionnaires, spreadsheets, slideshows, audios, videos, etc.) The peer and auto-evaluation was also considered a highlight by the students, since in French tertiary education this still remains an uncommon approach: “[…] the fact that we had access to the work produced by each group is rare, and very beneficial.” (Student D; Author’s translation).

Key criteria for learning with eLearning exchange networks (eLENs)

Siemens (2010) stipulates that learners need to experience a certain amount of “confusion and chaos in the learning process” and that “clarifying this chaos is the heart of learning”. It is paramount that they be in “control of their own learning” since “meaningful learning requires learner-driven activity”. After a five-year period conducting this sort of tutor-learner-peer collaborative work, it has become apparent that eLENS can be used successfully in tertiary education, as long as a certain number of prerequisites are clearly established. The main criteria are summarised in Figure 1 below.

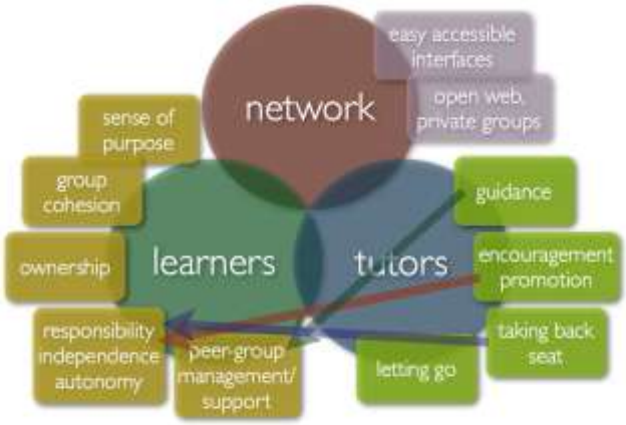

Figure 1: Our key criteria for effective learning and tutoring in eLENs

How can tutors adjust successfully?

In our experience, starting out from Marsh and Panckhurst (2006), through assessment of students' needs and recognition that more flexibility should be introduced into the curriculum, learners have been gradually taking *responsibility* for their own *autonomous/independent learning*, *sharing*, *peer-support*, *creation*, and they are in fact surfing the digital waves quite readily now. Weller (2011) focuses on "the digital scholar":

> Digital scholarship is more than just using information and communication technologies to research, teach and collaborate; it also includes embracing the open values, ideology and potential of technologies born of peer-to-peer networking and wiki ways of working in order to benefit both the academy and society. (Weller, 2011).

But how can "digital tutors" adjust? What positions, attitudes and roles do they need to adopt? As we know, "besides being experts in their respective academic disciplines, [Web] 2.0 lecturers have to be equipped with the necessary professional competencies (cognitive, teaching, technology, communicative, emotional, etc.) to successfully rise to the challenge of their duties in the 2.0 era." (Del Moral & Villalustre, 2012). But to succeed fully in the digital age, tutors also need to make sure the 6 steps indicated in Table 1 are carefully followed when organising online eLENs.

Table 1: Our 6 important steps for successful digital tutoring in eLENs

1.	Spend initial time carefully setting up and structuring the eLEN.
2.	Initiate ice-breaking activities (including surprise activities that create suspense) so that students can gain confidence, take ownership and feel trusted.
3.	Introduce structured imposed activities and stringent timelines.
4.	Make sure two tutors work together on each online course; this is important, so that they can provide support for each other and decide whether they should or should not intervene at precise moments.
5.	Let go of control — sit back and trust that learners, after initial tutor support and guidance, will progressively learn autonomously providing peer-support for each other.
6.	Accept and expect to make mistakes.

The most difficult lesson to learn for academics is to appreciate "the theoretical shift from instructor or institution-controlled teaching to one of greater control by the learner." (Siemens, 2008). Tutors need to take the back seat, but if they succeed in doing so, the effort is rewarded:

> This was a new, enriching experience but also disconcerting. Previously, I "reigned" [as a teacher], leaving little autonomy for students to lead their own discussions. My mere authoritative presence tended to hinder student communication. Here, a new perspective opened up. I realised that facilitating a group didn't mean imposing one's ideas, but remaining open-minded and leading skilfully. During the […] experience, I learnt to step back and delegate, so that others could readily participate. (Student E is also a teacher; Author's translation).

In our most recent case study (October 2011-January 2012), a new issue arose, related to virtual identity: several students refused to add a photo to their profile, perhaps because they felt that the shift to Google+ made them feel too virtually vulnerable. This was a novel aspect for the tutors, but they accepted this stance. However, several weeks later, one student group, who were working on multiuser virtual environments (MUVE), set up an appointment for the whole group with a person/avatar in a Second Life environment. This time the tutors, who nevertheless felt responsible for the group, were worried about the true identity of the real-life person, given that their website credentials and online information did not appear to be trustworthy. In this particular instance, the tutors sent a 'warning message' to the rest of the group. In hindsight, this was probably a mistake, and when the on-campus intensive session took place several students explained that they had felt that their autonomy, trust and responsibility had been slightly undermined on this particular occasion. The question that had arisen was nevertheless fascinating: for the tutors, identifying oneself over the Web with a photo was insignificant compared to trusting a total stranger, albeit a virtual one; for some of the students, the situation was the complete opposite.

Conclusion

Digital tutors/educators/facilitators are currently living in an era of *unease*. The paradigm shift has happened. A junior colleague who recently joined me on the second-year distance-education Master's course I run online, expressed the following: "I feel that my presence is totally unnecessary in this course; I don't know what position to adopt and it makes me uncomfortable." He subsequently suggested another colleague take his place next year, while I urged him to stay on. After hesitating for one or two months, he finally decided to stop co-tutoring the course. Notwithstanding, it is highly important to persevere. As digital tutors, we may well feel *uncomfortable*, as if we are doing very little when behind the scenes instead of being centre stage. But in *learning for the future,* less leadership and control from teachers and more ownership, responsibility and autonomy for students are crucial for learners. As digital tutors, we will gradually adjust and accept being able *to lose control and make mistakes*, learning both *with* and *from* our students — the true *future makers*.

Acknowledgements

I would like to thank Dr Fay Panckhurst for constructive remarks on a preliminary version of this paper. I would also like to thank Debra Marsh for fruitful exchanges over the past 5 years, resulting in co-authoring a number of articles related to eLearning pedagogical issues and co-tutoring a French online Masters' course using social network tools.

From shed to head: A conceptual toolkit for social sciences

Nigel Parsons
Politics Programme
Massey University

Scott Symonds
Centre for Teaching & Learning
Massey University

The conceptual toolkit is a heuristic device for teaching and learning key concepts and is grounded in Cognitive Load Theory (CLT). It focuses attention by stripping away extraneous material, encouraging a focus on the germane. This project brings the toolkit into virtual existence as a digitally animated interactive resource in the form of an extended metaphor. Key disciplinary concepts are represented as a 'tools' that can gain traction on data like a spanner on a bolt. Tools are acquired by learners and organized in a 'tool shed' ready for use. The tool shed allows students to organize concepts into memorable clusters; tools are organized on shelves akin to cognitive schemata in long-term memory. Subsequently learners may select tools appropriate to a specific 'job' and, extending the metaphor, these are placed into a traditional steel cantilever toolbox ready for use. Exercises then scaffold application and analysis, facilitating higher level thinking; tools are 'picked up' by working memory for application to tasks such as case study or comparison. Reflection on the suitability of tools selected allows for deeper synthesis and understanding.

Keywords: Conceptual toolkit, cognitive load, cognitive schemata, long-term memory, working memory

The metaphor of the toolkit

The 'toolkit' is an established pedagogical metaphor, with examples extending from philosophy (Baggini 2002) and ethics (Cooper 2008), to biology (Janssen 2008) proteins (Price 2009), conceptual modeling (Wieringa 2003) and urban infrastructure (NIWA 2012). The metaphor has also been extended to political thought (Roberts 2004); similarly, Heywood (2000, 2007), places an emphasis on concepts. This project extends the metaphor in a manner consistent with the lessons of CLT.

CLT and the toolkit

Mayer and Moreno propose multiple solutions to cognitive overload including "pretraining in names and characteristics of components" in a "mental model".

The tool shed: Reducing cognitive load

Stage one of engagement with the toolkit corresponds to "pretraining". This is done through acquisition and organization of tools for the shed; stocking the shed allows students to build "component models (i.e., representations of how each component works)." The shed stage requires "active processing" and encourages "meaningful learning", with students "mentally organizing the presented material into a coherent structure, and integrating the presented material with existing knowledge." Shelves in the shed are akin to cognitive schemata in long-term memory.

The toolbox: Encouraging higher level thinking

Stage two requires students to choose a small number of tools for a box appropriate to a particular job; selection and application to empirical material then facilitate construction of a "causal model (i.e., a representation of how a change in one part of the system causes change in another part, etc.). Beneficial outcomes include "better transfer" because "students know names and behaviors of system components" (Mayer and Moreno 2003). Tools picked up by working memory bring conceptual clarity to a case study or comparison.

The conceptual toolkit in Politics and Middle East studies

The toolkit reflects a teaching ethos and political commitment: that higher level thinking develops as concepts expedite analysis, analysis reveals patterns, and patterns render the complex comprehensible; and that education can empower individuals to analyse and so to read, listen or watch politics on a deeper level for themselves. The toolkit is intended to support learning within and beyond a tertiary environment.

One sample concept in Politics is legitimacy, a quality that “confers on a command an authoritative or binding character, thus transforming power into authority” (Heywood 2007: 219). For Weber, authority takes three forms: traditional, charismatic, and legal-rational (through mechanisms such as free and fair elections). Upheaval in the Arab world appears confusing. But the concept of legitimacy brings clarity, revealing deficits in the authority of Arab governments across the region and patterns in dynamic regional politics.

The toolkit is intended to have generic applicability; opening up the cognitive process to social science students in general could be done in tandem with the development of discipline specific learning skills. The capacity for ready customization is an integral feature of the resource: the ‘shed’ provides organization and storage space within which students can build a “component model” of concepts from Sociology, Social Anthropology or Human Geography as readily as Politics; the selection and application of concepts via a job-specific ‘box’ facilitates construction of a “causal model” with equally generic pedagogical value.

Development of a prototype of the toolkit is underway; a trial is planned with first year Politics students at Massey University during semester one 2013. The trial will be followed up with student evaluation using a tailored questionnaire via the Massey Online Survey Tool (MOST), plus peer review by social science colleagues from the GASP group within Massey University (Geography, Anthropology, Sociology and Politics). Feedback will inform further development of a stand-alone version that will be made publically available under a creative commons licence.

Responding to diversification: Preparing naïve learners for university study using Time Budgets

Diana Quinn
ITEE Teaching and Learning Projects
University of South Australia

Bruce Wedding
School of Electrical and Information Engineering
University of South Australia

Government reforms have resulted in an increasing number of pathways and options for a broader cohort of students to undertake university-level study. These diverse learners need support to develop successful study orchestrations, balancing available time for learning with competing interests, such as family, leisure and employment. The Time Budget is a useful tool for naïve students to perceive course workload, understand expectations and balance their commitments. The Time Budget, in a single page, captures what students need to do, and when, to be successful in their studies. Time Budgets have proved to be a sustainable good practice initiative for undergraduate students – a tool that has made the transition from supporting face-to-face learners, to blended and fully-online learners; and from being a feature of individual courses, to whole programs and multi-university collaborations.

Keywords: study approaches, expectations, workload, online, learner diversity, university.

Introduction

Prompted by Reviews of Higher Education, such as the Bradley Review, governmental policy changes have promised to transform higher education, to 'drive improvements in productivity and create a smarter, cleaner and more competitive economic future for Australia' (DEEWR, 2009). Strategies aim to increase the diversity of learners undertaking tertiary studies, with increased representation of students from low socioeconomic status groups, students who are first in their family to university, rural and remotely-located students and students from Indigenous backgrounds (Budge, 2010). These 'new new learners' (Budge, 2010), or naïve learners, are now entering university programs of study through multiple modes, studying face to face, online, and blended courses, and are requiring formal and informal support to make this study and life transition.

Enabling naïve learners for quality learning in higher education

The quality of learning experienced by university students is influenced formally by the academic community but also, informally, by individual student contexts, or presage, such as students' prior experiences, knowledge, reasons for studying, their perceptions of the teaching and learning environment and their approaches to learning and studying (Entwhistle *et al*., 2002; Biggs & Tang, 2007). The term 'study orchestrations' was coined to describe those individual study approaches, chosen by a student, based on their perceptions of the learning context (Meyer *et al*., 1990a). Supporting students to develop successful formal and informal study orchestrations is important to student persistence and retention in university level study (Anderson *et al*., 2011) and such strategies become more pertinent when system changes promote the diversification of the learner cohort.

Shaping perceptions of workload and approaches to study

Naïve learners, although feeling digitally connected through social media, may struggle to focus on their studies without sufficient guidance (Powers, 2010). A known motivator for undergraduate students' approaches to the quality and quantity of study is their perception of course workload. Excessive workload prompts plagiarism, surface approaches to learning and results in poor quality learning outcomes (Jones, 2011; Biggs & Tang, 2007; Kember 2004; Trigwell & Prosser,1991). Techniques for tallying student workload, by evaluating the difficulty of reading materials that two thirds to three quarters of students could satisfactorily complete, have been devised (Lockwood, 2005). University Assessment policies can also regulate the amount of workload across courses - for example, at the University of South Australia, a standard 4.5 unit course, has been equated to approximately 159.5 hours of student effort and 4500 assessed words (UniSA, 2012; requirements 1.2.2 and 1.2.5c). However, it is essential that naïve learners also perceive what this standardised workload entails and that it is achievable.

Successful strategies, that assist in conveying these perceptions to naïve learners, are required (Kember, 2004).

Introducing the Time Budget

A sustainable tool to help naive learners develop positive attitudes and approaches towards studying at university is the Time Budget. Time Budgets are a visual map of all that the student needs to do, week by week, across the period of study. The Time Budget was initially employed in introductory physics courses a decade ago, and since then has been incorporated in a variety of engineering courses, shared between universities in a cross-institutional blended learning project (Blackmore and Kane, 2010; Quinn *et al.*, 2012) and more recently, has been incorporated across all units in a mostly-online Open Universities Australia (OUA) Associate Degree in Engineering (James *et al*., 2011). The main aim of using Time Budgets has been to help students to adopt successful university-level study orchestrations for a given course.

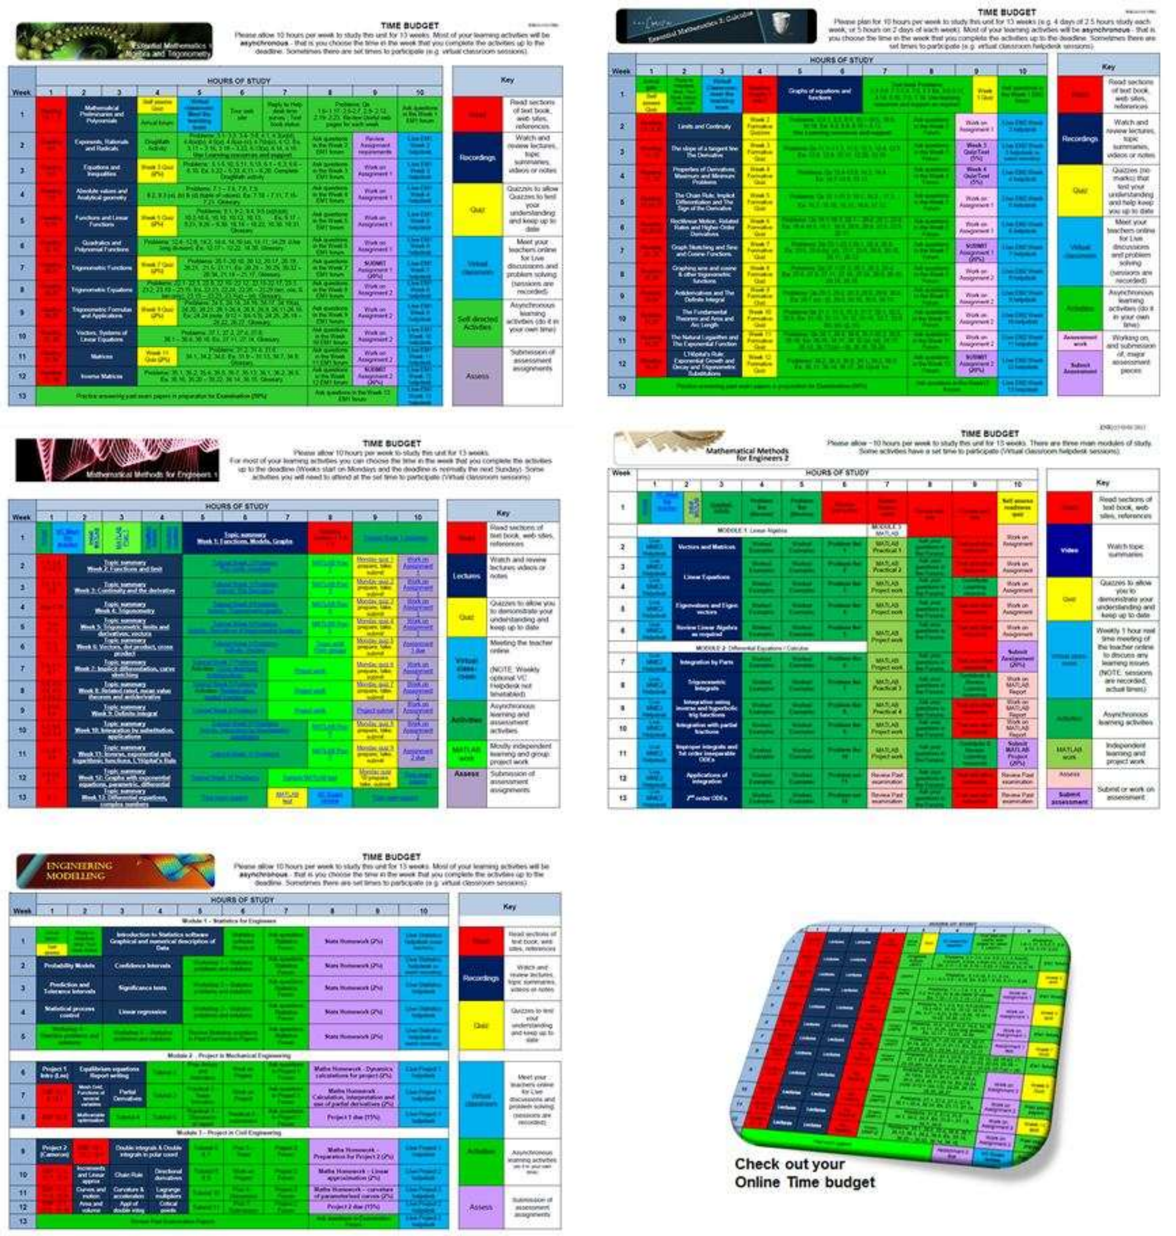

Figure 1 – Time Budgets from the 5 Mathematics courses in the Associate Degree in Engineering and the Time Budget logo used in all Units

Time Budgets emphasise time on task and task type and initiate the communication of expectations for high performance, two recognised principles of good practice in undergraduate teaching (Chickering & Gamson, 1987; LTU, 2010).

> Time plus energy equals learning. There is no substitute for time on task. Learning to use one's time well is critical for students and professionals alike. Students need help in learning effective time management. Allocating realistic amounts of time means effective learning for students and effective teaching for faculty. … Expect more and you will get it. High Expectations are important for everyone - for the poorly prepared, for those unwilling to exert themselves, and for the bright and well motivated. (Chickering & Gamson, 1987).

Case study: Time Budgets in an Associate Degree in Engineering

Time Budgets have been used in all the units prepared for a mostly online version of an Associate Degree in Engineering, delivered in partnership with OUA (James *et al*., 2011). The Time Budget documents were initially drafted by Project development staff in consultation with unit coordinators after interview and consideration of existing resources and environments. Iterative development of Time Budgets then occurred, in response to feedback from lecturers, tutoring staff, practical supervisors and, of course, students.

Paper-based versions of the final version of each unit's Time Budget were mailed to students on enrollment to be used as posters in their study space to provide a sense of the whole unit's requirements. The Time Budgets were consistently colour-coded to reflect when student learning activities are synchronous, or asynchronous, formative, or summative, instructive or interactive. In addition, online versions of the Time Budgets, with direct links to each of the activities, were included in the unit's web sites, to streamline students' navigation of the online environment to complete the required learning activities.

To support students using Time Budgets effectively, introductory quizzes, that allow students to self-assess how well they understand what is expected of them in the unit, included items that highlighted the importance of the Time Budget as an ongoing organisational tool. Students were prompted to use the document to negotiate adequate time for learning with their family and employers, who may be unfamiliar with the demands of university level study. Students were encouraged to identify early those timeslots, in their working week, that would allow them to learn for approximately 10 hours per week for each unit. Students were reminded that if they exceeded the time frames for independent problem solving allowed on the Time Budget, that it was time for them to change their approach to learning, by using Forums, virtual classroom sessions or Dialogue, to discuss their learning, rather than persist alone.

Time Budgets are not just for new learners, but are also used across programmes of study, inducting students to more advanced approaches to learning. Figure 1 shows a series of Time Budgets for the 5 mathematics units within the Associate Degree in Engineering. The first two units, *Essential Mathematics 1 & 2*, are more-structured foundational level units, with content, quizzes and problem solving activities. The second two are first year engineering level units, *Mathematical Methods for Engineers 1 & 2*, with time allowed for students to collaborate on an engineering project. The proposed Time Budget for the fifth unit, *Engineering Modelling*, contains separate modules for more independent study and two mathematical modelling projects, one addressing a civil engineering problem and one a mechanical engineering problem. Laying out the units as Time Budgets quickly conveys the macro-level learning designs of this series of units.

Aside from benefits for our students, Time Budgets have also proved to be a centre piece for the negotiation of redevelopment of units with developers and the unit's teaching team. By focusing on what students need to do, as reflected in a Time Budget, rather than what teachers need to teach, the Time Budget appears to be a more meaningful mechanism for staff to identify if the proposed learning experience of an online unit parallels that of its face to face equivalent. Also, the limitations of existing courses, such as heavy workload or an overly-didactic focus, become clearly evident, to all concerned, when mapped as hours of student work on a Time Budget. Research is currently underway to more fully investigate the role of Time Budgets in shaping successful learning approaches in our increasingly diverse student cohort as well as a parallel study on their impact in supporting staff conceptualise effective learning designs as a part of the course redevelopment process.

Conclusion

Australian Government Policy changes and flow-on higher education responses (James *et al*., 2011) have opened the door to allow a more diverse student cohort to start university. To ensure that this open door is not a revolving door, universities need to employ strategies, such as the Time Budget, to help induct naïve learners into successful study orchestrations, or the desired improvements in Australia's productivity, through the growth of a skilled work force, will be unlikely to be achieved.

This paper discusses our experiences of integrating a Multi-User Virtual Environment (MUVE) called *Quest Atlantis* into a pre-service secondary science education unit. The use of educational MUVEs as teaching tools is accelerating, so it is crucial that pre-service teachers develop some expertise with these and related technologies. We outline the processes we followed in embedding *Quest Atlantis* into the content and assessment of the unit, the results of this initiative and its implications for integrating MUVEs and other ICTs into teacher education programs. Challenges such as limited time and expertise, demands of a busy teaching program, and the need for continuous specialist support need to be overcome for sustainable integration of MUVEs and related technologies into pre-service teacher education. This is particularly important given the potential of pre-service teachers as change agents in schools, and the imperatives of the ICT-related National Professional Standards for Teachers and the Australian Curriculum.

Keywords: MUVE, Virtual World, Quest Atlantis, Pre-service teacher education, MMOG

Introduction

Recreational and educational use of Multi-User Virtual Environments (MUVEs) is accelerating in many parts of the world and teachers as future makers need to acknowledge and harness these technologies. The features defining most MUVEs include 3D graphical interfaces and chat tools that facilitate synchronous communication between multiple networked users represented by avatars (Dieterle & Clarke, 2009; Hew & Cheung, 2010). Many current MUVEs used in gaming contain highly engaging and motivating narratives that make them very appealing to users. There are more than 100 virtual worlds in existence or under development, and school leavers entering tertiary education are likely to have avatars and be using applications blending virtual worlds, games and social networking (de Freitas, 2008).

The same characteristics of MUVEs that make them so popular with adolescents also contribute to their enormous educational potential. Educational MUVEs blending online gaming and narrative with rich curriculum based content are becoming more widespread as teaching tools, and this increase is predicted to continue (Dieterle & Clarke, 2009; Hew & Cheung, 2010; Johnson, Adams, & Cummins, 2012a, 2012b). Examples include *Second Life*, *River City* and *Quest Atlantis*. In Australia, the increase in adoption of educational MUVEs at the school level is occurring in the broader context of the Digital Education Revolution (DER), a $2.4 billion federal government initiative aimed at better integrating ICTs into Australian schools (Department of Education Employment and Workplace Relations, 2012). The use of educational MUVEs is also accelerating in higher education institutions in Australia and NZ, as well as comparable countries such as the UK and USA (Dalgarno, Lee, Carlson, Gregory, & Tynan, 2011).

If our school teachers are to contribute to the DER by harnessing the teaching and learning opportunities afforded by MUVEs and related ICTs, it is vital they develop the experience and understanding to deploy them in the classroom. However, a global study concluded that a lack of knowledge on the part of school teachers was one of two major obstacles to integrating ICT in education (Pelgrum, 2001), and there is little evidence that this situation has changed markedly in the intervening decade. More specifically, reviews of the literature relating to MUVEs and related technologies in education (de Freitas, 2008; Kennedy-Clark & Reimann, 2010; Lawless & Pellegrino, 2007; Loveless, 2006; Schrader, Zheng, & Young, 2006) suggest that many school teachers may be less familiar with MUVEs than their students and are averse to using them and related technologies in the classroom. Some of the reasons for this are concerns about the effectiveness of these tools, as well as issues related to security, bandwidth and technology (Jones & Warren, 2011).

School teachers therefore require support and professional development in effectively integrating ICTs into their professional practice (e.g, review by Lawless & Pellegrino, 2007). It is therefore important that pre-service teachers (PSTs) are introduced to these technologies as an integral part of their teacher education programs, as argued by Fisher (2000). PSTs are more likely than their older in-service counterparts to be familiar with gaming and are often more open to using new technologies. Hence teacher education programs have a 'crucial role to play' in facilitating the use of multiplayer games and allied technologies in school classrooms (Fisher, 2000; Schrader, et al., 2006). It was concluded by Kennedy-Clark and Reimann (2010) that the more familiar PSTs are with virtual worlds, the more likely they are to consider using them in their subsequent teaching. However, studies indicate that PST programs often do not adequately teach PSTs how to integrate technology into their teaching, and that the ICT proficiency and confidence of PSTs is limited (Markauskaite, 2007). This is of some concern, and needs to be addressed if PST educators are to fulfill their potential role as "future makers" for the education of our next generation:

> When teacher educators provide the opportunities for pre-service teachers to practice meaningful integration of technology, while gaining the insights necessary for effective thinking and problem solving, a giant leap toward better schools for the future shall have been made (Fisher, 2000, p. 112).

In order to enhance PSTs' understandings and attitudes towards ICTs such as MUVEs, many strands of evidence argue for an integrated, authentically embedded approach. The TPACK theoretical framework of Mishra and Koehler (2006), for example, articulates the close relationship between learning how to teach with technology and the pedagogical and content knowledges of the teaching and learning context. While advocating the adoption of multiple strategies, Kay (2006; 2007) cites many studies emphasising the importance of authentic teaching tasks and an integrated approach embedding ICT into the array of units comprising PST education courses, as opposed to generic stand-alone units or add-on workshops, an approach also advocated by Lawless and Pellegrino (2007). This aligns with what we know about situated cognition (Brown, Collins, & Duguid, 1989), and assessment as the driver of the curriculum for students (Rowntree, 1987).

This paper introduces a case study in which an educational MUVE – *Quest Atlantis (QA)* – was integrated into the content and assessment of a core science education unit taken by pre-service secondary science teachers., It outlines our rationale for integrating QA, describes how we embedded the technology within the unit and discusses the enablers and barriers we encountered in this process. We hope that the lessons we learned from this exercise might encourage and inform similar initiatives in the future.

Integrating *QA* into pre-service secondary science education

Context of the study

This study emerged as one of several innovations incorporated into our teacher education programs as part of the Teaching Teachers for the Future project. This is a federally funded initiative aimed at enabling PSTs to effectively use ICT in education ("Teaching Teachers for the Future," 2012). The project was undertaken by an experienced ICT Pedagogy Officer, who had been appointed on a contract to the wider Teaching Teachers for the Future project, and two members of the secondary science education team who although reasonably technologically savvy had little direct experience with MUVEs. The intended outcomes were first, for the PSTs to learn about the science education potential of MUVEs like *QA* and second, for the learning experience to contribute to their own broader TPACK.

Choice and description of MUVE: Quest Atlantis

Of the available options, we chose to introduce the PSTs to *QA* for several reasons. First, *QA* is a free, very secure scenario-based MUVE aimed at children from 9-16 years old. It is already being used in public and independent schools in NSW, Queensland, Tasmania and Victoria. Second, *QA* embeds over 1000 curriculum-based interactive quests with integrated and customizable assessment tasks in a very engaging and motivational narrative, combined with a very strong focus on social responsibility. Third, the development of *QA* was informed by theories of transformational play, which locates learners and the content to be learned in an online game-play context (Barab et al., 2007; Barab, Thomas, Dodge, Carteaux, & Tuzun, 2005). For example, learners can be scientists doing virtual water quality testing, or they can be managers, making difficult decisions about strategies for national park management. Their actions and decisions have consequences which impact on the narrative and relate to complex socio-scientific issues that mirror some of the complexity of the real world. Unlike the real world, learners can travel into the future and see the consequences of their decisions.

Notwithstanding these real strengths, there are some inherent challenges in using *QA* as a teaching tool in Australia. One is its North American context apparent in the vegetation and choice of organisms in graphics and some quest tasks. For the most part this raises few problems, however in the case of the ecological topic used in this project, an Australian environment featuring local flora and fauna would provide a more locally relevant context and better suit the syllabus outcomes. Hence, even though *QA* tasks can be customized to some extent by teachers, some experience and a reasonable investment of time would be necessary to make particular topics applicable to Australia. In addition, as part of the quality assurance mechanisms built into *QA*, teachers must gain accreditation by undertaking an online training course. While this is a very reasonable step, participating in this course does require a reasonable investment of time by teachers.

Integration methodology

For many of the reasons outlined above, we took the decision to fully integrate *QA* into one of the core science units studied by 49 pre-service science teachers (PSTs) enrolled via distance education mode. The ‘Using ICTs in science’ topic within the unit was revised to incorporate *QA*, and a major assessment task was customised around students’ *QA* experiences. The Project Officer extended her previous accreditation to enable her to train teachers, and the two science teacher educators undertook the necessary training to become accredited *QA* teachers.

The PSTs were required to download *QA* onto their home computers, and to familiarize themselves with Adobe Connect. Adobe Connect was used in the training sessions alongside *QA* as it permits text and audio communication along with desktop sharing. This provided a means of talking to students outside the *QA* application (which is text only), as well as allowing the trainer to troubleshoot any technical problems as they arose. It also allowed training sessions to be recorded. A number of *QA* training sessions were scheduled in order to cater for the PSTs’ work and family commitments. Training was coordinated and conducted by the Project Officer. Once training was complete, the PSTs were required to undertake some preliminary quests, and then progress to an ecological sustainability topic called “Taiga”, which focuses on the importance of water quality and related ecological, social and economic issues.

Taiga was chosen because many of the concepts in the unit address outcomes in the NSW Year 7-10 science syllabus. The scenario also highlights the interplay between scientific, economic and social aspects of sustainability extremely well. This was particularly appealing given that sustainability is one of three cross-curricular perspectives of the new Australian Science Curriculum. The students were required to complete part of the Taiga quest for the assessment task, though they could complete the remainder if they so desired. As well as writing about the quest itself and its applicability to the classroom, students were also asked to discuss their experiences of using *QA*.

Lessons learned

This process had some lessons for us about dealing with the challenges in deeply integrating innovative ICTs into PST education units. Time was one challenge, as it took considerable time to redevelop the existing unit and build the associated assessment task and marking criteria. This was ameliorated by some teaching relief as part of the project. The limited experience and expertise of the science teaching staff in *QA* was another challenge that was overcome through the expertise and support of the Project Officer together with *QA* support staff.

Another category of challenges related to PST access to hardware, software and expertise. Some of these related to the fact that the unit was a distance education class distributed across Australia and abroad, rather than an on-campus group in a computer laboratory. Even though all the students were familiar with the hardware and network requirements associated with studying at a distance, one student could only access a computer sporadically, and technical problems occurred trying to load the application onto the computer lab that he could access. Some experienced *QA* “hanging” and had to log out and in again. This was difficult during the training process but greatly ameliorated by having Adobe Connect running in parallel, although this seemed to cause bandwidth limitations for some users. Some difficulties were encountered with real-time access to IT support as the platform is hosted in the US. Some students with less experience than others in ICTs and/or MUVEs found the learning curve particularly steep. The training workshop series had to be repeated several times to accommodate the timetables of the PSTs, including evening sessions. None of these problems were major, but trouble shooting them required considerable time and the combined expertise of the Project Officer, science teaching staff and support staff.

In terms of the consequences of this project, it is pertinent to note that students’ experiences of *QA* and reflections on what they had learned were very positive. All students explored and gained some familiarity with *QA*, and 25 students completed all steps required to gain formal accreditation to be *QA* teachers in their own classrooms. Overall findings from analysis of in-depth interviews are described elsewhere by Doyle and Reading (2012). In summary, many of these students moved from initial resistance to appreciating the possibilities of MUVEs such as *QA*. They also recognised that they developed a range of associated ICT skills along the way. Many saw the value of the training they had received and saw a place for educational MUVEs in PST education. Standard centrally administered student evaluations of the unit were as good as they usually are, indicating that students remained well satisfied with their learning experiences in the unit.

Just as important were the impacts on two of us: the science teaching staff who were involved in this process, some of which are summarised by Reading and Doyle (2012). We learned about the difficulties that our students experienced during their training by being in-world with them, and shared many of their difficulties ourselves. We developed our ICT skills and saw the enormous potential of MUVEs such as *QA* in science teaching and learning, particularly in dealing with the thorny issue of cross-curricular perspectives in secondary education where teachers still work predominantly in their own subject silos.

In the longer term, notwithstanding the successful implementation of the project, the decision was made not to include *QA* and the associated assessment in the unit in the following year. This was in large part because the Project Officer’s project-funded contract was due to expire before the next iteration of the teaching unit. Despite the gains in understanding and experience of the science teaching staff, we could not justify taking the time from other teaching, research and administrative responsibilities to repeat the process without the vital support and expertise of the Project Officer. In addition, this left more opportunity to address some of the many other science-specific and generic ICTs that could have been covered in the unit. However, the process has undoubtedly and significantly deepened the knowledge and understanding of MUVEs for the science teaching staff, and puts us in a much better position to connect PSTs to these and other related ICTs in different learning and teaching contexts.

Discussion and Implications

The case study outlined above illustrates some of the real challenges to some of the emerging directions of teaching and learning in PST education, as foreshadowed in this conference theme. Although the project deeply embedded a high quality MUVE into a disciplinary unit, in a way that satisfied many of the characteristics of good practice suggested by the literature reviewed above, this was not sustainable in the longer term. This outcome relates to four interconnected challenges that we were not able to overcome: time demands on academic staff, limited relevant ICT expertise of academic teaching staff, tensions between breadth and depth of ICT integration in a busy PST education program, and the need for continued high quality support and professional development from ICT specialists.

Previous studies (e.g., Kay, 2006) have also indicated that time demands have posed a barrier to effectively implementing ICTs in PST education programs. A recent report addressing the challenges faced by tertiary educators in Australia emphasises the problem of time constraints, suggesting that academic staff are ‘struggling to manage existing workloads’ (Bexley, James, & Arkoudis, 2011, p. xi). Strongly related to juggling overstretched time budgets is the issue of limited relevant ICT expertise of the curriculum area specialists, which was also raised as an issue by Kay (2006). Embarking on any new learning curve is time consuming, and integrating “innovations” almost by definition stretches the time commitments and expertise of faculty staff who may not be ICT specialists. These problems in tandem relate to a consequent fear of technological problems, which are very demanding of both time and expertise, and this is another known barrier to integrating ICTs in PST education (Kay 2006).

In relation to program constraints to ICT integration, it must be noted that this initiative focused primarily on MUVEs, with ancillary use of Adobe Connect. However these are only two of a huge palette of ICTs with which PSTs should be familiar. There is a limited number of ICTs that can be covered in any depth within a disciplinary unit with several other graduate attributes to integrate, and although this project facilitated deep integration of one promising and innovative ICT, it also narrowed the ICT palette to which the PSTs were exposed. To meet the future challenges of teachers requires ongoing selective evaluation and integration of some of the rapidly expanding ICT options into teacher education. To manage this in a sustainable and representative way requires serious consideration of course structures by mapping gaps, overlaps and opportunities across programs; and maximizing complementary links between curriculum subject areas, ICT-focussed units and any central or generic ICT workshop programs. The TPACK conceptualization (Mishra & Koehler, 2006) provides a useful framework for strategic mapping and planning, and its application has been shown to have contributed to PST TPACK (Galstaun, Kennedy-Clark, & Hu, 2011; Hu & Fyfe, 2010). There is good evidence that collaborative partnerships between universities, schools and education authorities (Kay, 2007; Pegg, Reading, & Williams, 2007) are particularly promising approaches, though implementing this kind of professional development has also been shown to be constrained by time and workload constraints for PST educators, as well as the PSTs and teachers (Pegg, et al., 2007).

One of the solutions to the limited time and limited expertise of PST educators that initially facilitated this project was appropriate support and professional development. As noted by Kay (2006), there are many ways that ICTs in general can be introduced into PST education programs, but ultimately good support of the PSTs is a key access consideration, without which many other strategies would have little effect. The commitment and expertise of the Project Officer was essential in driving the project, conducting the training and troubleshooting technical problems. Without this support, the PSTs enrolled in that unit (and the PST educators running it) would not have had such a good opportunity to experience the learning possibilities afforded by an educational virtual world in science education. However, as is becoming more common in the increasingly casualised Australian higher education sector (Bexley, et al., 2011), the Project Officer was employed on short term contract, which was not able to be renewed once the project funding ceased. One-off injections of funds and short-term strategic projects can impact on the institutional ICT-related culture and knowledge base, but as we found, sustaining the impact requires sustaining the support.

Many of the challenges that are outlined above to integrating MUVEs in particular, and ICTs more generally into PST education are equally relevant across the higher education sector. However, several features of PST education programs mark them as particularly important in this regard. Preservice Teachers are indeed ‘future-makers’. They occupy a pivotal position as potential change agents in the ICT literacy of our society (Pegg, et al., 2007), with the capacity to influence the preceding generation of older in-service teachers, and future generations of school children. The importance of this role is underscored by the recently endorsed National Professional Standards for Teachers, three of which relate directly to knowledge and practice of ICTs (AITSL, 2011). Similarly, ICT is one of three cross-curricular perspectives mandated by the new Australian Curriculum. It is the responsibility of PST educators to help PSTs meet these standards and meet the curriculum requirements. It has been predicted that MUVE-like technologies will form a component of “the updating of teacher education” (Schrader, et al., 2006). This is already happening via applications of virtual worlds such as VirtualPrex project (Gregory et al., 2011). Systemic considerations of the time, expertise, curriculum and support requirements of academic staff in non ICT teaching areas would greatly facilitate the more widespread adoption of MUVEs and other technologies in PST programs.

Acknowledgements

This research was funded by the Teaching Teachers for the Future project, an initiative of the Australian Government through the Information Communication Technology Innovation Fund. We are very grateful to Chris Reading for steering the broader project at our institution and facilitating our involvement. We would particularly like to extend our thanks to the students who participated in this study and to Bron Stuckey for so generously sharing her time and expertise to facilitate this project.

Designing to close the gap

Alison Reedy

Charles Darwin University

This paper reports on the initial phase of the development of a large scale online design and implementation project, known as the ACIKE Online Unit Development Project, for the Australian Centre of Indigenous Knowledges and Education (ACIKE). The project is underpinned by a design-based research framework and encompasses the design, development and staged delivery of 81 units across seven higher education undergraduate and post-graduate courses. The rationale underpinning the project is to promote Indigenous learners' participation and success in higher education, with a particular focus on the online environment, whilst providing opportunities for all students to develop the skills and knowledge to work cross-culturally in a learning environment focused on building Indigenous cultural competence.

Keywords: design-based research, educational design, Indigenous, higher education, templates

Introduction

The higher education environment in Australia is being reshaped by funding, policy and regulatory changes in line with a vision to create 'an outstanding, internationally competitive tertiary education system to meet Australia's future needs' (Bradley et al., 2008, p. x). This vision of a sustainable future entails a broadening of the participation base in higher education, particularly from groups of people currently under represented, including 'Indigenous people, people with low socio-economic status, and those from regional and remote areas' (Bradley et al., 2008: xi).

The Australian Centre for Indigenous Knowledges and Education (ACIKE) is one institution taking up the challenge to increase the participation of Indigenous learners in higher education. ACIKE is a joint initiative of Charles Darwin University (CDU) and Batchelor Institute of Indigenous Tertiary Education (BIITE) which commenced delivery of courses in 2012. ACIKE offers a learning environment that aims to 'provide pathways to build the social, human, economic and identity capital of Indigenous peoples across Australia' (Charles Darwin University, 2011a).

The ACIKE model represents a significant shift in the way in which higher education is being offered to Indigenous people in the Northern Territory and across Australia. ACIKE offerings incorporate digital technologies into the learning mix. Units of study offered in internal, external and intensive workshop modes all utilise learning materials and activities developed in Learnline, CDU's version of the Blackboard Learning Management System (LMS). The inclusion of online learning as a component of all delivery modes in ACIKE has the potential to engage Indigenous and non-Indigenous learners with each other and with content in new ways; however, this approach is not without challenges and setbacks.

Access to computers remains a stumbling block for Australian Indigenous learners accessing higher education. This reality suggests that assumptions about the benefits of the integration of technology across ACIKE courses require careful review and evaluation. Indigenous Australians experience reduced access to computers and the internet as compared to the wider community (ABS, 2008) as well as facing issues which compound access such as low levels of English literacy, the user-friendliness of the location of public access computers, and restrictions to computer usage as a result of avoidance relationships and connections to the land where public access computers are located (Daly, 2005; Nicholls, 2009; Reedy, 2010; Vodic et al., 2012). CDU's rollout of a mobile learning environment in the second half of 2012 provides opportunities for leaners to access and engage with Learnline content using smart phones, iPads and other mobile devices even when they do not have discretionary access to an internet enabled computer. The potential of the mobile augmented learning environment to enhance Indigenous student participation is highly exciting but it is too early yet to measure its impact.

The ACIKE Online Unit Development Project

This paper reports on the first twelve months of the ACIKE Online Unit Development Project which involves the design and staged development and delivery of 81 Learnline units. The first, though necessarily brief, part of the ACIKE project was spent conceptualising the design of the ACIKE online learning environment. The initial design period was informed by research and review of literature in educational design, with a particular focus on Indigenous pedagogies, as well as by the context of the project. This period was somewhat constrained by the pragmatic realities of the eighteen month timeframe for the project deliverables to be achieved and the competing agendas and power dynamics that played out in the relationship between the project partners.

The early design work led to the first iteration of the ACIKE Learnline template, which provides a framework for the development of online units, providing consistency in design, navigation and approach. The template assists academic staff in the development of units and enhances the usability of Learnline sites for students. The template provides a practical guide for academics moving into developing and teaching in the online space for the first time. The template also embodies best-practice design principles (Akarasriworn et al., 2011), a student-centred approach to learning, and is underpinned by social justice principles which are in alignment with ACIKE's goals and the broader CDU strategic aim to position the university as a first choice destination for Indigenous Australians seeking higher education and as 'a leader in the teaching and understanding of Indigenous knowledge systems' (CDU, 2010, p. 6).

The design process is underpinned by an understanding that online learning spaces reflect and reinforce 'values, ideologies, and images that are motivated inclusions and exclusions which act in the interests of particular cultural, class and gendered groups' (Luke, 1988 in Henderson, 1994, p.10). The ACIKE Learnline template is intended to provide a framework for online learning which reflects the ACIKE context and which promotes the success, retention and completion of Indigenous people in higher education courses and which provides all students with 'the knowledge, skills and understandings which form the foundations of Indigenous cultural competency' (Universities Australia, 2011, p. 181).

Rationale

Recent data show that Australian Indigenous students are completing year 12 education at higher rates than ever before (ABS, 2011; Karvelas, 2012). There are, however, significant challenges and changes required in order to ensure that school completion rates for Indigenous students match that of the wider Australian population and that year 12 completion translates to increased and equitable representation of Indigenous students in higher education. In Australia, Indigenous access, participation, success and retention in tertiary education are significantly lower than that of the general population. Australia wide, the Indigenous participation rate in higher education sits at 1.25% and would need to more than double to 3% to achieve parity compared with the total number of domestic students participating in higher education. (DEEWR, 2011a; DEEWR, 2011b)

The Northern Territory (NT) has an Indigenous population comprising 32% (ABS, 2010), and is the state or territory in Australia with the highest Indigenous population as a proportion of total population. The Indigenous participation rate in higher education in the NT of 15.63% represents students enrolled in both BIITE and CDU in 2006, prior to the ACIKE partnership, and while this is higher than other states, it is lower than the rate which would represent parity with the Indigenous population of the NT (DEEWR, 2011a). The ACIKE partnership faces the challenge of capitalising on the strengths of both organisations to design the conditions that optimise Indigenous students' access, participation, success and retention in higher education, arguably at a rate that matches or exceeds the pre-ACIKE Indigenous combined participation rate in higher education.

Design-based research

Design–based research is increasingly used in the field of technology-focused educational research. The characteristics of design-based research include situating research within an educational context and the design of an educational intervention and testing of it over many iterations and refinements. Design-based research results in reflection, theorizing and the development of practical design principles which may have wide application.

In many respects design-based research is similar to action research in that it 'seeks to increase the impact, transfer and translation of education research into improved practice' (Anderson & Shattuck, 2012 p.16) although design-based research has the potential to be wider reaching than action research as it moves beyond a practitioner researcher approach to one that involves a design team which includes partnerships between practitioners and researchers. Despite this potential, most design-based research literature reflects small-scale educational innovations and interventions (Anderson & Shattuck, 2012; Barab & Squire, 2004) rather than larger-scale interventions with widely applicable outcomes. The scope of the ACIKE Online Unit Development Project, with a focus on the design and delivery of 81 units, has implications for online unit design and delivery within ACIKE and potentially more broadly across CDU and BIITE. The scale of the research in testing a ‘disrupting innovation’ (Anderson & Shattuck, 2012, p. 24) pushes the boundaries of design-based research and will potentially lead to new understandings of what works for Indigenous learners in the online environment in the ACIKE context as well as developing theoretically grounded design principles which address broad systemic issues to do with inclusion and exclusion of Indigenous knowledge and issues in a wide range of university courses.

Methods

The development of design-based research is characteristically informed by a mixed method approach to data collection, including the use of qualitative and quantitative methods. Design-based research is a process with the focus of data collection methods changing as the research progresses through iterative phases of development, with qualitative methods used primarily in the early phases of design, implementation and preliminary evaluation, and quantitative methods introduced ‘as the design is re-evaluated, refined [and] scaled up’ (Bowler & Large, 2008, p. 41).

In the early phases of the ACIKE project a review of literature and semi-structured interviews with Indigenous students already using Learnline at CDU provided focus for the initial design of the ACIKE Learnline model and the subsequent template which was designed to guide unit development in the LMS. Feedback from a focus group comprising of BIITE and CDU staff was used to refine the initial template design prior to implementation by the ACIKE Online Unit Development Team in partnership with academic staff from BIITE and CDU. The development of the first 38 ACIKE Learnline units, based on the initial template, occurred in preparation for delivery in Semester 1 2012.

Evaluation of the first phase of the project is planned but has not yet commenced. Evaluation will encompass review of the design process, the ACIKE Learnline model and template, and evaluation of individual ACIKE Learnline units. An instrument to evaluate exemplary Learnline units at CDU, currently under development, will be used to review individual ACIKE Learnline units and as a tool for providing feedback to academic staff to guide iterative development of online units. Subsequent cycles of evaluation will include interviews with academic staff, tutors, students, members of the ACIKE Online Unit Development Team and others involved in the project. The range of data collection methods and sources of data will assist in providing triangulation of research findings and thus support the validity of the design principles that emerge from the project.

Reflections

As the first phase of the ACIKE Online Unit Development Project nears completion, and formal evaluation has not yet commenced, it is too early to reflect on the research findings or to divine the final design principles that may emerge. The following section, however, presents some reflections on key elements of the project to this point.

Alignment of priorities and focus of project partners

A major innovation such as the ACIKE Online Unit Development Project requires alignment of direction and focus from the leadership and staff of the project partners from the beginning of the project. As with other recent design-based projects the issues of ‘project structure and power relations and negotiations aimed at realising conditions for real partnership’ (Leeman & Wardekker, 2011, p. 313) were possibly not given sufficient consideration prior to the commencement of the project. In the ACIKE project a shared understanding of the project goals, and processes to achieve these, were negotiated and articulated through a project plan. In addition, a communications strategy was put in place to ensure formal communication and reporting processes were in place at all levels of the project. Despite this, the articulated vision for the project has been impacted by the partners’ differing political agendas and assumptions of entitlement and ownership. In addition, differing priorities on issues such as staffing and workload management have impacted on the timely achievement of the project milestones.

Co-operative diversity

The ACIKE project has benefitted from a rich array of formal and informal collaborative partnerships, including those within the ACIKE Online Unit Development Team itself. These have provided opportunities for creativity and innovation in the project design and implementation. A defining characteristic of design-based research is that it involves collaborative partnerships between researchers and practitioners (Anderson & Shattuck, 2012).

This recognizes that any individual will not have all the knowledge to negotiate the complexities of research, design and implementation nor the diverse range of knowledge and skills needed for successful innovation and change implementation. The progress made in the ACIKE project is characterized by a high-performing team which has leveraged diversity of experience and background between practitioners and the project team and channeled this into the project.

Teacher preparation

Findings from a recent design-based research study advise that 'for any major innovation to succeed, the teachers involved need to be adequately prepared and to be in a position to make a difference' (Leeman & Wardekker, 2011, p.324). In the ACIKE project, training of teachers to use Learnline, the ACIKE template and in teaching and learning in an online environment was conducted concurrently with the initial design phase of the project. There was little time for ACIKE staff to prepare for the new learning environment, and unit development for the online environment has been, in most cases in addition to teaching and administrative responsibilities. This had an impact on the opportunity for systematic and consistent development of quality online units and on the timeliness of unit development.

Conclusion

The ACIKE Online Unit Development Project is an example of a large scale educational innovation underpinned by design-based research. The scale of the project and its application across courses and disciplines provides the opportunity for the emergence of theoretically grounded design principles, refined in the context of ACIKE, which will potentially impact on online course design across CDU and more widely to broaden participation in higher education by Indigenous students. The project aligns with the Australian Government and CDU's vision of broadening educational participation to groups currently under-represented in higher education. The vision of increased participation by Indigenous students in ACIKE is yet to be realised. Indeed, the project has been characterised by the messy reality of research conducted in the 'buzzing, blooming confusion of real-life settings' (Barab & Squire, 2004, p. 4) where it has suffered set-backs linked to the competing agendas of the project partners and seemingly impossible time constraints. Against this backdrop the design, development and delivery of the first phase of ACIKE Learnline units has been achieved, with ongoing development, trialling, evaluation and iterative development of the ACIKE Learnline template continuing. The contribution of this project to ACIKE's vision of providing pathways and building sustainable futures for Indigenous Australians is anticipated to be significant, however, the claims about the potential of new models of delivery and approaches to learning and teaching in the online environment in the ACIKE context are yet to be fully implemented and evaluated.

Digital communities – contexts for leading learning into the future?

Shirley Reushle, Jacquie McDonald
University of Southern Queensland

In 2011, a robust, on-campus, three-element Community of Practice model consisting of growing community, sharing of practice and building domain knowledge was piloted in a digital learning environment. An interim evaluation of the pilot study revealed that the three-element framework, when used in a digital environment, required a fourth element. This element, which appears to happen incidentally in the face-to-face context, is that of reflecting, reporting and revising. This paper outlines the extension of the pilot study to the national tertiary education context in order to explore the implications for the design, leadership roles, and selection of appropriate technologies to support and sustain digital communities using the four-element model.

Keywords: digital, interaction, collaboration, leadership, community of practice

Introduction

McLuhan's (1968) claim that we live in a "global village" has certainly proved correct. Digital communities can provide opportunities to engage with a national and international community of learners or colleagues around a particular domain of practice. However, research and experience reveal that many of these digital communities are not sustained, and the authors propose that effective leadership and a sound design framework may be the key elements for success.

This work-in-progress builds on research conducted with an established three-element model that has proved robust to guide campus-based, face-to-face Communities of Practice (CoP). This initiative has been successfully operating at the University of Southern Queensland (USQ) since the pilot project in 2006 and the number of successful CoPs has grown to twenty (McDonald, 2010; Star & McDonald, in press). The three-element model structures interactions according to Wenger's (1998) combination of three fundamental Community of Practice elements:

1. A domain of knowledge that creates a common ground and a sense of common identity (builds member capacity);
2. A community of people who care about the domain and create the social fabric of learning (grow a learning community);
3. A shared practice developed to become effective in the domain (innovations are noted by the participants and this saves reinventing the wheel).

In 2011, the three-element CoP model was trialled in a digital environment with the ascilite Community Mentoring Program (Reushle, 2011). Outcomes of that trial suggest that appropriate leadership in a digital community can create the conditions of motivation (inspiring members to be involved), attachment and identity (keeping members involved). The authors are extending the trial to include national digital communities, researching both the design and leadership aspects of digital communities. To effectively support the digital communities, appropriate technologies will also be identified.

Moving from local to digital communities

Participation in communities of practice builds on the premise of social learning theory that we are social beings, who learn best in social contexts (Vygotsky, 1978; Wenger, 2010). CoPs can foster peer interaction, changes in practice and build learning communities. At USQ, the three-element model of growing community, sharing of practice and building domain knowledge has been used as a unique organising framework for CoP gatherings and has provided an effective working model for professional development to support academics in the reshaping of higher education theory and practice (McDonald & Star, 2008). Communities of Practice do not have formal institutional structures or hierarchical leadership and reject meeting-style activity, preferring to refer to any synchronous activity as gatherings. The focus for any activity generally emerges from member negotiation and there is continual potential for new direction. Active participation and collaborative decision-making is encouraged and members may assume different roles with hierarchical, authoritarian management replaced by self-management and ownership of work (McDonald & Star, 2008). The community focuses on authentic tasks and activities and members are able to share ideas and resource, debate and build expertise within a safe and supportive community. Six years' of experience and research in the Australian context by a co-author of this paper has identified that leadership (as opposed to "management") is a crucial element for CoP success and sustainability (McDonald & Star, in press).

Learning and teaching in higher education is changing rapidly to address the imperatives of digital futures. Developing knowledge and experience of how to effectively lead and support digital communities is critical to enhance skills and practice that can be applied across diverse learning and teaching contexts. However, in an ever-increasing digital environment (influenced by events such as the roll out of the National Broadband Network, increasingly diverse cohorts of students, collaboration with colleagues across the world), it is imperative that educators have the confidence, skills and motivation to effectively employ digital communities in their daily work. It is also critical that they model the effective use of digital communities for their students and address the disconnect highlighted by Ohler (2010) who notes that many educational systems still force learners to have "two lives", their "traditional educational (lives) within school" and outside of school, their "digital lives".

In 2011, the USQ three-element model was trialled in a digital environment with the pilot ascilite Collaborative Community Mentoring Program. A preliminary evaluation of the pilot revealed that the digital CoP enabled peer support and collaboration by providing access, convenience, flexibility, utility, speed, and cost-effectiveness. On the other hand, some participants indicated a lack of sustained engagement with the community. One participant noted the difficulty in "making the program a high priority. It kept slipping down the list of 'things to do'. I often felt distracted from my project goals and, due to conflicting demands on my time, this made me feel frustrated that I could not progress my project outcomes. Although I felt fully supported, I was not fully committed" (Reushle, 2012, p. 5). Further informal investigation of these issues suggests that the effective operation of digital communities also appears to be highly dependent on visible, consistent and astute leadership. CoPs have emerged as a non-hierarchical structure that attempts to re-engage academics in learning and collegiality and yet, there is little research about leadership and role definition within such structures.

The evaluation also revealed that the three-element framework, when used in a digital environment, required a fourth element, that of reflecting, reporting and revising, something which appeared to happen incidentally in the face-to-face context. This four-element model (Figure 1) provides the basis for the design of a digital community and will now be tested for application to support productive connections in other Australian tertiary contexts.

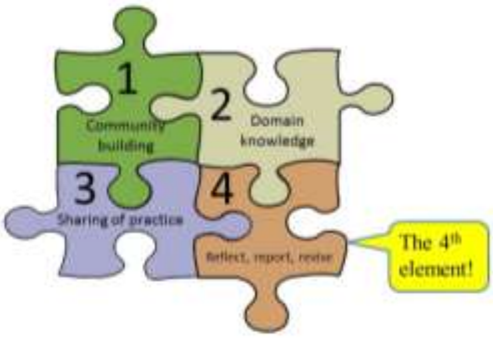

Figure 1: 4-element Community of Practice model

The digital community design and research plan

The authors will proceed through an iterative, reflective, action learning approach. The four-element model - community building, sharing practice, building domain knowledge, and reflecting, reporting and revising - will provide the design framework for the next stage of the digital communities' trial. Collegiate structures, including CoPs, seem ideally suited to the style of leadership espoused by Kotter (1990, cited in Anderson & Johnson, 2006, p. 3) who suggests that "leadership is about influencing and engaging others to effect change". Thus, the role of leadership in community building, orchestrating the sharing of practice and the building of domain knowledge and expertise are important for CoPs to lead change and transform practice.

Leadership of digital communities must also recognise the special conditions of this social, community-based form of engagement. Facilitating community is not a static, one-time event related to switching on an electronic platform or suite of technologies. There also seem to be a number of significant questions to be answered relating to the digital literacy skills of the community members and what is regarded as productive engagement within a digital community, particularly the affective level of that digital literacy. Do people feel attached to online collaboration sufficiently? If so, which people and why? At some level, leadership may fail if those who are to be part of that digital community are not in tune with the modality of interaction, even while agreeing to its importance. Do digital communities bring members closer or, for those less experienced in the digital environment, can the very tools being used lead to a greater sense of separation? What is the fit between engaging in a digital community and the learning to be a member of that community (where learning may be the sense of becoming adept at its modes of operation)?

While technologies can assist in providing a platform for communication and collaboration, even more important is the social construction of the community. The technical architecture supports the community, while the social architecture enlivens it. The roles, processes, and approaches that engage people - whether face-to-face or online - are essential in relationship building, collaborative learning, knowledge sharing, and action. Together, technical and social architectures create the container for the community (EDUCAUSE, 2012). Through mediated interaction, distributed in time and space, with many less formal markers of community, the environment tends to involve more numerous, but weaker ties between participants and ensuing bouts of passive engagement or occasional bursts of activity. This apparent weakness, compared with more traditional communities can also be a strength, where leadership focuses specifically on promoting the ties between people, based on common interests and affiliations at the individual level.

The authors propose that the tenets of distributed leadership (Scott, Coates, & Anderson, 2008) may be more appropriate for digital communities and investigation of participant expectations and appropriate leadership activities will be a focus of this research. A crucial feature of distributed leadership is a focus on empowering colleagues that leads to capacity building. Through the practice of distributed leadership, people at all levels engage in action and demonstrate leadership in their own areas of expertise.

The authors will review the current literature and conduct surveys to identify key leadership issues and needs of members of digital communities, and identify key informants for follow up focus groups and interviews, if required. Qualitative data will be collected through these interviews to identify key themes regarding the leadership requirements of digital communities. A number of trial digital communities are being established which will use the four-element model and be facilitated through the application of the leadership skills identified in the literature, and through the data from the surveys, focus groups and interviews.

Identification, evaluation and implementation of technologies to support the four element design will operate concurrently. Further surveys and interviews will be conducted post-pilot, with the findings used to develop a model for digital communities' leadership capacity building and the refining of the design elements for digital communities of practice.

Conclusion

The authors contend that leadership in the digital context must promote links between individuals within the community (enabling community to emerge), rather than focusing only on linking all individuals to a single collective entity, "the community". This implies that digital communities need to have mechanisms for members to share resources, ideas and expertise, thus building the capacity of its participants as well as building strategic collaborations within the community. Laycock (2012, para. 6) has noted that "many well-meaning leaders in fact strangle their communities through their zeal to direct all communication between participants through its platform" and believes that this is "unnecessary and denies the multiple ways in which we as human beings naturally interact". The aim is to foster a culture of shared ownership and commitment noting that there is strong evidence of the close relationship between shared leadership, responsibility and capacity building (Crowther, 2011). This enhances the capacity not just of one or two people but of many and enables a broad distribution of leadership functions, talents and responsibilities.

The authors will investigate the application of a four-element model, a number of identified leadership skills and range of technologies to determine which is most effective in providing a framework and platform for communication and collaboration to support the social architecture of the digital community. The project will address leadership questions and build leadership capacity for digital communities and has the potential to generate sectoral wide benefits by providing validated, generalisable examples and opportunities to influence practice.

NPC: an online model to improve prescribing skills of health care professional students in Australia

Jorge Reyna
Educational Designer
NPS MedicineWise

Santosh Khanal
Evaluation Officer
NPS Medicine Wise

The National Prescribing Curriculum (NPC) is a series of case-based modules that mirror the decision-making process outlined in the World Health Organisation's Guide to Good Prescribing. The emphasis is on learners building their own formulary of preferred drugs for specific conditions thereby enabling them to prescribe confidently and rationally. The modules were developed to overcome shortfalls in basic pharmacological knowledge and prescribing skills as identified by junior hospital doctors. Problem Base Learning (PBL) has been used as pedagogical approach for the modules and includes real life case scenarios, authentic tasks and expert peer feedbacks. Learners can access the modules at their own pace and also can revisit them upon completion. We report for the first time students' perceptions of the NPC as learning resource and usability issues, and how academics are embedding the NPC modules into their units. We also discuss limitations and possible areas of improvement.

Keywords: prescribing skills, national prescribing curriculum, online healthcare education.

Introduction

The development of the National Prescribing Curriculum (NPC) was a response to the need expressed by junior doctors in Australia in 2001 (Smith et al., 2006), and prescribing errors and adverse drug reactions that remain the most common cause of injury to hospitalised patients (Nichols et al., 2008, Bobb et al., 2004, Roughhead & Semple, 2008). This percentage of error appears to be increasing and has significant consequences for patient safety (Heaton et al., 2008, Maxwell et al., 2006). This could show dissociation between lectures and clinical reality that health care professionals face when they finish their studies. This gap has been also described in other disciplines like education (Buckingham 2005; Schon 1987; Stigler and Hiebert 1999; Smith 2000). One of the possible reasons of this dissociation can be the fact that some real life situations may not be explained adequately in traditional face-to-face teaching contexts and requires a technological intervention (Reyna, 2011). On the other hand, prescribers are facing progressive demands due to more licensed medicines available, increasing indications for drug treatment, greater complexity of treatment (polypharmacy) and more elderly and vulnerable patients (Maxwell & Mucklow, 2012).

In this regard, online learning as an alternative approach could showcase effective prescribing practices, promote dialog on critical issues in the field, help students to apply theory to practice, and create enthusiasm and confidence in the learner to implement safe practices. There are other factors that could influence prescribing such the environment, team, individual, patient and task (Basket, 2010). Prescribing is an important part of medical practice but may not necessarily be a strong focus in the training of medical students or other health professionals. Safe-prescribing skills and awareness of medication errors is required by all members of the health care team, and should be a core component of undergraduate and postgraduate training programs (Coombes et al., 2008).

In order to overcome these issues, the National Prescribing Services (NPS) decided to develop the NPC as a web-based course founded on the World Health Organization's Guide to Good Prescribing (de Vries, 1994). The resource currently comprises 28 modules covering common therapeutic topics from COPD to Diabetes, polypharmacy, hypertension, lipid management, etc. The modules have been designed for individual, self-paced learning or can be used as part of small group work. Module content is written by subject matter experts and undergoes a rigorous peer-review process, similar to that followed by peer-reviewed journals, during their development. Educational designers review the content to ensure that it is appropriate for online delivery and that the tasks are meaningful and meet the learning outcomes. Evaluators at NPS design formative and summative research to gather the impact of the modules on students' knowledge construction and to find areas of improvement.

Problem Base Learning (PBL) was identified as pedagogical approach for the NPC modules. This approach was considered to be the most suitable to overcome the gap between traditional didactic lecturing and the clinical reality that their students would eventually face, so we decided to base their instruction on real-case scenarios. Students will need relevant medical knowledge to solve a clinical problem presented on the module. Since the instructors at McMaster University's Faculty of Medicine developed Problem-Based Learning in 1969 (Albanese and Mitchell, 1993; Vernon and Blake, 1993), this pedagogical approach proved to be a successful in the area of medical education. Currently, 70% of medical faculties in the US use PBL in pre-clinical years (Kinkade, 2005). PBL has been successfully implemented in various disciplines, such as architecture (Maitland, 1997), business (Stinson and Milter, 1996), education (Duffy, 1994), law (Driessen and Van der Vleuten, 2000), social work (Boud and Feletti, 1991), engineering (Fink, 1999; Woods, 1994) and physics (Wiliams, 2001).

The NPC modules have been designed as a logical progression where learners can engage in their own way with their patients, discuss therapeutic goals with their peers, choose the optimal non-drug and drug therapy, prescribe medicines and get expert feedback. Additionally, learners can advise the patient how best to use the chosen therapy and finally, test their knowledge gained using review questions built in with expert's feedback at the end of the module. After completion, the learners can revisit the modules and can print My Formulary that contains the drug classes and prescribed medicine used across the different modules.

Recently, the focus of the NPC has diversified to include other health professionals, and minor adjustments have been made to accommodate this change (e.g. replacing the specific term 'doctor' with a more generic term of 'prescriber'), but the overall structure of the course has been kept the same. It has been shown that short prescribing courses run locally by universities and hospitals enable new prescribers to develop their own personal formulary of preferred drugs for specific conditions and to improve prescribing (Bennett-Levy et al., 2009). The NPC differs from these courses with the fact that is more flexible due to the online nature and it is the only nationally available course for students and health professionals from multiple healthcare disciplines.

Research questions

(1) Is the NPC a valuable learning resource for the students?
(2) Are there any usability issues with the module design?
(3) What are academics perceptions of the NPC?

Materials and Methods

Learning Design

A typical NPC module has the following logical progression: (1) Introduction to the condition and learning outcomes; (2) context/case study that defines who and where the learner is for the purpose of the module; (3) a list of short term therapeutic goals where learner can nominate, vote and see their peers' votes; (4) expert's feedback on therapeutic goals as guidance; (5) consider a non-drug treatment and submit their answers following by expert's feedback; (6) choose the appropriate drug treatment for the condition; (7) verify the suitability of the treatment; (8) select drugs and prescribe online followed by feedback written by the expert; (9) feedback on the prescribed incorrect drugs that may cause adverse reactions; (10) monitor patient progress via multiple choice question and instant feedback from expert; (11) provide information to the patient and followed by the expert's ideas, and; (12) multiple choice quiz to give a quick review of the module. Every time learners submit their answers they will get an instant expert feedback.

The NPC follows the 3 essential characteristics of a good learning design according to Britain (2004): (1) learning is active; (2) activities are presented in a logical progression; and (3) the template is reusable. The delivery method is for self-paced learning but flexible enough to be use in face-to-face tutorials. In fact many academics introduce the modules on tutorials at the beginning of the semester and provide the login details for the students.

As the NPC content is written by content experts with vast clinical experience, the case study presented in each module is authentic. The tasks and the level of interaction that learners get involved promote a conceptualisation of the patient, development of critical thinking and problem-solving skills, considering different ideas of treatment, and meaning of feedback.

Technical specifications

We have developed our modules using Flash professional and they are hosted on a commercial Flash-based e-learning platform. Each module takes learners approximately one hour to complete. Learners access the modules through a self sign-in process, organised through their universities. The main features of the NPC website where the modules are contained can be summarised as: (1) self-registration for students; (2) drugs tool; (3) my formulary tool; (4) writing prescription tool; (5) authoring tool; and (6) monitoring tool.

(1) Self-registration for students
The educational designer at NPS creates a group for each university or organisation on the database. Inside these groups, cohorts are created upon academic request at the beginning of each semester. When a cohort is created and modules are included, the educational designers assign a course key and email sign-up instructions for students to relevant academics. Students for each of these organisations have to self-register into their university and course. The self registration page can be found at www.nps.org.au/npc.

(2) Drug tool
The drug tool is a database that is organised by condition and it is classified in drug classes. A drug class might have lots of brands of products under it. Each product comes with information such efficacy issues, safety issues, commentary and resources. Inside the drug class there are different types of products available and contain details such drug name, form, strength, directions, quantity, repeat, cost, other issues and commentary. Links with additional information are placed inside the drug tool. Most of the links comes from the Australian Medicine Handbook (AMH), Therapeutic Guideliness (eTG) and NPS website. This is an example to visualise the structure of the drug tool; *Drug Class> Anti-infectives > antibacterials > aminoglycosides > drug name: Gentamicin.* Each module has a drug tool that allows learners to choose a medicine at the time of prescription.

(3) My formulary tool
This is a centralised application that takes input from the drug tool. It stores the drug choices from students as well as their notes and in which modules they have chosen them. It also implements a My Formulary page that will display the drugs that the students have added to it (when and by which module they have added them). Additionally, the Formulary tool provides data for the Write Prescription tool so the student can choose which drugs they need to write a prescription.

(4) Writing prescription tool
This is a tool that allows students to complete and submit an online prescription with the drugs they selected for their patient in a previous step. When they submit this prescription they will get expert feedback. Learners are able to search for drugs in their formulary, select drugs for the prescription, enter doctor, patient and drug details into the prescription, preview and print the prescription (if desired) and get feedback from an expert on the correct prescription. The prescription tools have the same fields as those used in Australian public hospitals and general practice and look similar.

(5) Authoring tool
This area is exclusively for the educational designer and contains the sequence of activities covered in the learning design part. This section allows the designer to build the series of interactions the module will follow.

(6) *Monitoring tools*
This section is for academics who want to see their student progress. The grade book is a functionality that allows gathering information of the whole cohort and reports on a spreadsheet the activities of all the students inside the cohort, particularly currently visited and completed modules. This is a useful feature for academics.

Methodology

Online surveys and forms were used to gather quantitative and qualitative data. All NPC registered students at the time of the study (n=4,339) were invited to participate on a voluntary base. A link to a cross-sectional questionnaire containing 18 questions was e-mailed to students. The questionnaire captured demographics of participants, completion of modules, student's attitude and perception of usefulness. Quantitative data was analysed using SPSS v.19. Descriptive statistics were calculated for all variables. Analysis was undertaken for all questions of all applicable respondents. Qualitative responses were analysed using a structured process in which key phrases and concepts were identified, the data categorised, and recurring themes and issues recorded. NPC usage data was gathered from the server for year 2011. Due to system setup and limitations, data on usage implied a tedious manual process, which is the reason why it was done only for last year. Additional qualitative data from academics was gathered at the time they were requesting a new NPC cohort via online form early in January 2012.

Results and discussion

Demographics of participants
A total of 442 (10%) valid surveys were received and almost all respondents had completed at least one module (94%, n=417). Among the entire sample almost two thirds were female (66%, n=292). The highest proportion of respondents were from New South Wales (NSW) (28%, n=125). The next highest proportion of respondents were from Victoria (VIC) (21%, n=94) and Queensland (QLD) (16%, n=71); there was also considerable response from Tasmania (TAS) (14%, n=63).

Approximately 80% of all respondents were studying medicine. The remaining respondents were made up primarily of pharmacy students (14%, n=62) and nurse practitioners and dentistry. This makes sense as the modules were primarily targeted for medical students but pharmacist and nurse practitioners are finding the NPC modules relevant and useful for their disciplines.

Completion of modules
Although the greatest proportion of respondents indicated that some or all of the modules were compulsory (58%, n=257), it is also of note that almost one quarter of those who completed a module indicated that they were not compulsory (25%, n=109) (Table 1). A quarter of all respondents also indicated that the modules were linked to assessment (26%, n=113). Students most commonly completed 4 modules (15%, n=62). However, there were 52 students (13%) who completed all 25 modules.

Table 1: Use of the modules in the curriculum

	% (n)
Modules not compulsory	25 (109)
Some/all modules compulsory	58 (257)
Some/all module completion counted to course mark	13 (56)
Some/all modules linked to assessment	26 (113)
Other	4 (18)

Chronic obstructive pulmonary disease (COPD) was the module completed by the greatest proportion of students (64%, n=266). This is also the first module to be displayed in the series of modules which may influence the uptake and completion by students. Other frequently completed modules include chronic heart failure (59%, n=247), post-operative pain (56%, n=234) and acute pulmonary oedema in chronic heart failure (49%, n=205) (Table 2).

Table 2: Top 10 NPC modules completed

	% (n)
M1: COPD	64 (266)
M9: Chronic heart failure	59 (247)
M4: Post-operative pain	56 (234)
M8: Acute pulmonary oedema in chronic heart failure	49 (205)
M16: Polypharmacy in multiple system failure	49 (204)
M18: Anticoagulation in atrial fibrillation	48 (200)
M11: Acute coronary syndrome	48 (200)
M19: Prophylaxis of deep vein thrombosis	47 (196)
M6: Confusion in an elderly woman	46 (193)
M10: Urinary tract infection	44 (182)

Ranking of usage per module

In calendar year 2011, there were a total of 19,895 completions for all modules by learners across Australian universities from medicine, pharmacy, nurse practitioner and dentistry. Ranking of usage per module has been calculated taking into account the total number of modules completed vs. the specific module figures, for example in M1: COPD there were 1,044 learners that completed this module (1,044/19,895 *100= 5%). Data presented on Table 3 shows that the students used the modules evenly. For modules 26 and 27 the percentage of usage were low as they were new modules rolled out 6 months ago when the study was conducted. This data was crucial to decide whether we decommission modules with low usage. Our concern was that students can be overwhelmed by having to complete 28 modules as each module takes 1 hour. Although the data on Table 1 shows that only in 13% of the cases modules are counted towards course mark, so students can decide whether or not to complete the whole set of modules. It will be required in the future to ask the students what they think about having 28 modules, what the optimum number of modules would be to improve prescribing skills? For example, it could be that NPC modules need to cover more modules or fewer modules will be required for students to understand the prescribing process and to feel confident with their skills. To elucidate these questions further research need to be conducted.

Modules names are: (M1) COPD; (M2) Peptic ulceration with H. pylori; (M3) Peptic ulceration with NSAID use; (M4) Postoperative pain and vomiting; (M5) Opioid dependency; (M6) Confusion in geriatric patient; (M7) Confusion associated with alcohol withdrawal; (M8) Acute pulmonary oedema; (M9) Chronic heart failure; (M10) Urinary tract infection; (M11) Acute coronary syndrome; (M12) Chronic angina; (M13) Hypertension; (M14) Respiratory tract infection in a child; (M15) Seizure; (M16) Polypharmacy; (M17) Anaemia; (M18) Anticoagulation for atrial fibrillation; (M19) Prophylaxis in deep venous thrombosis; (M20) Adolescent depression; (M21) Analgesics in persistent pain; (M22) Glycaemic control in long-established diabetes; (M23) Long term management of type 2 diabetes P1; (M24) Long term management of type 2 diabetes P2; (M25) Insomnia; (M26) Opioid analgesics in chronic non-cancer pain; (M27) Lipid management and CVD risk; (M28) Acute mania in bipolar disorder; (D1) Facial pain; (D2) Sore mouth; (D3) Bone problems.

Table 3: Ranking of usage per NPC module in 2011

Module	No. Students completed	%	Module	No. Students completed	%
M1	1044	5	M16	1145	6
M2	852	4	M17	606	3
M3	817	4	M18	795	4
M4	881	4	M19	749	4
M5	584	3	M20	520	3
M6	799	4	M21	681	3
M7	557	3	M22	665	3
M8	964	5	M23	683	3
M9	999	5	M24	651	3
M10	746	4	M25	613	3
M11	781	4	M26	473	2
M12	663	3	M27	363	2
M13	870	4	D3	21	0
M14	531	3	D1	27	0
M15	712	4	D2	103	1

Students' attitude

The general attitude among the student responses towards the module tasks, content, relevance and navigation was overwhelmingly positive (Table 4). There was a high level of agreement (approximately 95%) that the module tasks were engaging, that the instructions easy to follow, the content clearly presented and that the modules were relevant to (anticipated) clinical experience. There was also encouraging results in regards to the module learning objectives which were found to be clear. The tasks in the modules were also found to adequately address the objectives (approximately 95% agreement). Interestingly, more than 40% of students indicated that they would not be more motivated to complete the modules if they were formally assessed. Approximately 30% indicated that the modules did not increase awareness of other NPS products, suggesting improvement could be made in the promotion in the modules of other NPS resources. There was some disagreement (approximately 20%) in the ease of navigation of the modules.

Table 4: Attitudes toward content, navigation, learning objectives and other aspects of the modules

	SA	A	D	SD
	% (n)			
Module tasks were engaging (N=415)	22 (92)	74 (307)	4 (15)	0 (1)
Instructions easy to follow (N=414)	29 (120)	66 (271)	5 (22)	0 (1)
Content clearly presented (N=414)	30 (122)	67 (276)	4 (15)	0 (1)
Relevant to (anticipated) clinical experience (N=414)	38 (156)	59 (244)	3 (14)	0
More motivated if formally assessed (N=414)	21 (87)	39 (161)	37 (154)	3 (12)
Links to other resources useful (N=415)	23 (97)	61 (255)	15 (61)	1 (2)
Increased awareness of other NPS resources (N=415)	18 (75)	51 (213)	28 (117)	2 (10)
Learning objectives clear (N=415)	21 (88)	73 (303)	5 (22)	1 (2)
Tasks addressed the learning objectives (N=417)	23 (95)	74 (302)	3 (12)	0 (1)
Easy to navigate (N=413)	22 (92)	57 (234)	18 (74)	3 (13)

(SA) Strongly agree; (A) Agree; (D) Disagree; (SD) Strongly disagree.

Perception of usefulness of NPC

Approximately 90% of learners positively responded when asked about the impact of the modules on developing critical appraisal skills and, and whether the modules were effective in testing understanding of the content rather than just memory. More than 90% of learners agreed or strongly agreed that the feedback was adequate to guide decision making. Almost all students considered the feedback from experts to be useful (52% strongly agreed and 46% agreed). The usefulness of access to peers' answers and ideas was less but at 80% agreement, the result is still very positive (Table 5). There were also 20% of students who indicated that they were not encouraged to complete the modules and may indicate room for further promotion among academic staff.

Table 5: Attitude towards module feedback, developing skills and encouragement to complete

	SA	A	D	SD
	% (n)			
Effective for developing critical thinking skills (N=412)	23 (96)	65 (266)	11 (46)	1 (4)
Tests tested my understanding – not just memory (N=414)	28 (117)	65 (267)	6 (26)	1 (4)
Expert feedback was useful (N=413)	52 (214)	46 (188)	3 (11)	0
Adequate feedback to guide decision making (N=412)	24 (99)	66 (270)	10 (40)	1 (3)
I was encouraged to complete NPC modules (N=414)	22 (92)	58 (239)	17 (71)	3 (12)
Access to peers' answers/ideas useful (N=414)	23 (95)	57 (235)	18 (74)	2 (10)

It will be necessary to gather students' perspective of what they learn as it has been proved to be effective when evaluating the effect of curriculum innovation on students' learning. This data will identify variations between groups of learners, and will allow conclusions to be drawn about the quality of students'learning. This systematic analysis is known as phenomenography and has been described in educational psychology (Ellis et al., 2007; Matthew *et al*., 2007; Marton and Booth, 1997; Prosser & Millar, 1989).

Academic perception of NPC modules
When we asked academics (n=38) at the time of sign up for 2012, 64% reported that they use the NPC in both 1st and 2nd semester while only 11% in 1st semester and 6% in 2nd semester. Fifty-two percentages of academics informed that they use the modules for year 4 and 5 students. Only 14% of academics were willing to help NPS with the following tasks: (1) Identifying students to give a testimonial about their experience with the NPC modules for promotional purposes (written or filmed); (2) Research and/or evaluation activities and studies involving the NPC modules; (3) Reviewing/updating the content of the NPC modules. This was not a surprise as we know academics have competing schedules. Additionally, 75% of academics who signed up for NPC in January 2012 had positive comments about NPC as learning resource, as example:

> I think NPC modules are relevant, I like the stepwise progression ... they're very thorough ... I really like the emphasis on non-pharmacological treatment to start with, they sort of encourage the student to think about the whole case and the whole patient ... they're also used by the majority of schools and universities in Australia and it's sort of good to know it's a consistent approach being used across the country.
>
> I think that the standard of prescribing both in doctors and medical students needs overall to be improved and I think that the NPC modules are doing an excellent job.
>
> The NPC is a very good resource; it presents a logical progression for students to follow when making clinical decisions. I believe it has a lot of interaction that allow students to engage with it in their own way.

Limitations of NPC modules
There are several limitations of the NPC modules related to functionality, cross device compatibility, and social presence. We are currently working on a strategy to overcome these issues.

The NPC modules have a functionality called grade book that allow academics to export an Excel spreadsheet with the list of their students and stage of completion of the modules. The main limitation of the NPC modules is for assessment purposes, not all of the interactions are captured on the database. List of short term therapeutic goals (Step 3 in sequence) and also providing information to the patient (Step 11) are recorded on a database but this is not accessible to academics on the report. Data on multiple choice questions in: considering a non-drug treatment (Step 5), monitoring patient progress (Step 10) and multiple choice quizzes designed to give a quick review of the module (Step 12) cannot be captured. Medications used by learners in different modules can be exported as PDF but academics will not have direct access to this information. All of these are technical limitations that need to be addressed in order to promote NPC modules into the curriculum as assessment tool for academics.

The NPC interface is design in Adobe Flash which is not compatible with portable devices running iOS platform (Apple devices). Adobe also announced that will not support Flash for mobile devices. These portable devices are changing the way we organise our everyday life, learning resources and tasks;

allowing us to increase productivity. Because of their portability, large display, and touch screen, tablets are ideal devices for one-to-one learning, as well as fieldwork. According to the NMC Horizon Report in Higher Education (2012), tablets have come to be viewed as not just a new category of mobile devices, but indeed a new technology in its own right. They blend features of laptops, smart phones, and earlier tablet computers with always-connected Internet, and thousands of apps with which to personalise the experience. The NMC report mentioned that the time to adoption is 1 year or less. We are currently studying the possibility of migrating our modules from Flash to HTML5, CSS3 and JavaScript in the near future. The aim is to extend cross device compatibility which will help us reach more learners and also improving their learning experiences.

It has been described before that one of the major components of student satisfaction in online learning is the levels of interaction. High levels of interaction result from highly cooperative learning environments (Simonson et al., 2012). Educators are challenged to seek and implement tools and strategies that recreate face-to-face human elements of cooperation, immediacy, intimacy that model physical classroom experiences (Gunawardena & Zittle, 1997). Social presence is the awareness of interaction partners over a communication medium (Short, Williams & Christie, 1976). The NPC modules have a weak social presence and students can only see how their peers replied on the therapeutic goals section (Stage 3) and also in considering a non-drug treatment (Stage 5). A better way to connect learners may be developing an online learning community promoted by instant messages where students can create a profile for online discussion and sharing of resources, etc. In this space learners can discuss and consider ideas and learn from each other in a constructive manner. An online learning community of users will help to create social presence, build cohesion and elevate student's attitudes, performance, satisfaction and student engagement (Ring, 2012).

Additionally, it has been reported the use of video cases in PBL scenarios to be a valuable stimulus for group discussions in medical students. Students thought the video cases enabled them to create realistic mental pictures of conditions, provided integrated pictures of patients as people, which challenged them to elaborate the cases seriously and were more memorable than text-based cases (De Leng et al., 2007). We are considering including digital video in future NPC modules to describe the case scenarios and possible patients concerning. Digital video provides a natural medium for enhancing the sense of context and realism in case studies. It can capture the complexity of real life scenarios and allow students to replay events as many times as they need and absorb important features that escaped them on first viewing (Reyna, 2010).

Limitations of the study

The study has been focused primarily with an evaluation rather than a research approach to estimate how valuable to the students the NPC is as a learning resource. Although the NPC modules follow a Problem-Based Learning approach commonly used in medical education, does not use a conceptual framework to be tested. We are planning in the future to strength our relationship within the universities involving academics in the design process of the NPC modules taking into account a conceptual framework for learning based on a constructive alignment. This will give us opportunities for future research and improving students learning experience.

Conclusions

From the data presented, it is clear that the NPC modules are valuable learning resource for students. This leads to accept the first research question we formulated. We need to promote the NPC modules within pharmacist and nurse practitioners to increase the uptake in these disciplines. It will also be necessary to further evaluate student's perception of learning. A good model could be phenomenography as has been shown to be effective when evaluating technological intervention in the curriculum.

In regards to the second research question about usability of the modules, only 20% of students indicated to have some issues navigating the modules. This could be due to technical issues like Flash player and Java platform. However, when students move to tablet computing, this may become an issue for the drawbacks that Flash has for touch screen interfaces and no compatibility for iOS devices such iPads, iPhones and iPod touch.

Overall academic perceptions about NPC modules were positive and they are up taking the NPC modules within their units, especially for year 4 and 5 students. Limitations in terms of functionality may prevent them from using the NPC modules as assessment tools. Issues with cross device compatibility, social presence and inclusion of digital video, if addressed, could have a positive impact on student's engagement and enhance the learning experience. We are looking forward to implementing these in the near future.

The advance of educational technology coupled with competitive forces, ever-increasing digitisation, and new entrants into the Higher Education sector, has created an environment of constant change for those working within it. This paper discusses how seven people, in five institutions across three countries joined forces to develop their knowledge, skill and ability in conducting and reporting on educational technology research for institutional impact. Reviewed in this paper are a range of approaches adopted across the different institutions, considerations of which of these have been effective and examination of whether targeted communication strategies have helped overcome inherent barriers.

Keywords: educational technology research; institutional impact; reporting; higher education.

Introduction

The advance of educational technology coupled with competitive forces, ever increasing digitisation and new entrants into the Higher Education sector has created an environment of constant change for those working within it. As both educators specialising in technology and as academics utilising the technology, we have a responsibility to lead, and support those in leadership, in these times of change. We can accomplish this through our dual roles of encouraging users and assisting educational change whilst at the same time supporting academics to embrace a new educational environment. The challenges include developing our knowledge and skill as well as conducting and reporting on educational technology research for institutional impact. The authors review the approaches taken across the different institutions, consider the challenges of those approaches, reflect on the lessons learnt along the way and evaluate the effectiveness of the resultant strategies adopted.

The problem in context

With technology developing at an ever-increasing pace, the information and research on how it can be applied in education is overwhelming. Institutions are relying on technology to solve many of the current and emerging challenges in higher education. In spite of this constant change, academics are slow to adopt new technology

(Laurillard, 2010). The role of the educators who specialise in technology to evaluate the information and report to stakeholders is becoming more important. Leaders who make strategic decisions in this climate of change rely on the information we provide about resourcing and costs. Fellow educationalists are looking for information about features and functionality. Academic staff who need to buy-in as the users of new technology need information on how to apply the technology to the best advantage pedagogically as well as the potential barriers to be overcome. Clearly, there is no single approach that will secure buy-in on all those fronts. In the light of those challenges, we are exploring ways of communicating successfully, drawing on our collective experience in the field.

Multi-national collaboration – what we did

Seven people across five institutions from Australia, New Zealand and South Africa joined the ascilite Community Mentoring Program in 2012 as mentors/mentees to work collaboratively to achieve similar goals. Communication has been through *Skype*, Adobe Connect, emails, a group wiki and other online means. Since 2003, the ascilite Community Mentoring Program has been bringing people together to share experiences and develop their knowledge through dialogue, action and reflection (Reushle, 2012). The benefits of the ascilite Community Mentoring Program are to expand skills, knowledge and experience, develop communication and leadership skills, network and enhance confidence (Reushle, 2012).

The team consists of mentors from the University of New England, Armidale, and Charles Sturt University, Orange, (both Australia), who are mentoring educationalists from North-West University, Potchefstroom Campus, South Africa, University of Pretoria, South Africa, University of Canterbury, New Zealand and two from Charles Sturt University, Wagga Wagga, Australia. The two mentors are academics in ICT Education and Strategic Learning and Teaching Innovation respectively. The mentees are instructional and educational designers, an academic for research methodology programs, a flexible learning advisor and an innovation technology officer, hence defining us collectively as 'educators specialising in technology'. These seven represent a plethora of experience and knowledge.

The group meets via *Skype* and Adobe Connect because it accommodates the diverse locations, technical skills and is cost effective. A Dropbox folder enables us to share files and a secure wiki facilitated the collaborative writing of this paper. Cut-off dates helped coordinate all contributions into a seamless paper. The research question we posed as an overall theme was:

"How can we, in our different capacities, conduct our own research or keep up to date with the current research, to evaluate and report to different stakeholders on new education technologies for maximum institutional impact?"

Methodology and literature review

As a framework for organising an overview of our institutions' strategies for communicating educational technology research we drew on strategies developed by Surry and Land (2000) from Keller's (1987) ARCS model. Keller describes his original model of Attention, Relevance, Confidence and Satisfaction as "a method for improving the motivational appeal of instructional materials" (Keller, 1987, p. 2). Surrey and Land (2000) developed a framework of strategies, and it is within this framework that we consider the levels of motivation at which we reach out to our stakeholders to achieve our goals. A meta-analysis of the cases (see Table 1) was carried out to determine if there is any pattern in what works and in which type of environment. In this way we can pinpoint where each institution can learn from other institutions.

The ARCS framework, when used to motivate staff to use teaching technology, identifies reporting to grab the 'attention' of the intended audience in order to raise awareness of new technologies and arouse the curiosity. Providing 'relevance' to the particular context of staff members can be accomplished by highlighting the ways in which a technology can fulfil their present needs. To engender 'confidence' in the use of the technology an extended approach is needed in the form of training and support. Rewarding staff through awards and reporting success stories and innovations creates an environment where staff can set attainable goals, share experiences with like-minded colleagues and experience 'satisfaction' which is the highest order of motivation. Surrey (2000) writes of using Keller's (1987) ARCS model to develop strategies to increase faculty motivation to use technology. Attention gaining strategies include demonstrations and showcases, Relevant strategies; include access to equipment and mini grants for research opportunities, Confidence building strategies such as workshops and peer support, and satisfaction strategies such as awards, release time and improve teaching and research.

Reporting research to gain attention is relevant for bottom-up, top-down and sideways dissemination and can utilise technology-assisted gimmicks (bells and whistles). The message can be non-personalised to speak to a wide audience and personal involvement is negligible. The direction we report to will dictate the relevance we add to the communication, as we need different kinds of buy-in from each audience. Knowledge of the different audiences is needed and used to adapt the messages so that the intended audience can recognise themselves in the communication. Connecting people is very important (Laurillard, 2010), as is creating and supporting professional learning communities (Maor & McLoughlin, 2005; Nicolle & Lou, 2008).

To communicate for confidence becomes more specific, as messages need to be tailored to the individual. Personal involvement increases as we often have to spend time with individuals in a mentoring capacity to ensure fluency and confidence. "Instrumentalist theories of change, therefore, are based on the premise that adoption and utilisation of technology are highly individualised and contextualised processes" (Surry & Land, 2000, p. 146). The audience should also be encouraged to reflect on the new information and consider its use in constructing solutions. Satisfaction may be assured by encouraging staff to become innovative and apply their knowledge in new ways, in teaching or another sphere of their academic life.

Much of the literature considers the dissemination of educational technology research, not in isolation, but as an element of a wider program of educating higher education faculty for a particular purpose. This purpose has been to encourage academics in implementing the use of technology for teaching, much of it in a blended learning or online context. A wide variety of methods of dissemination have been used with varying success. The traditional lecture/seminar has been a part of each set of tools used in communication educational technology research, but by no means the most successful. Maor explains that, "a common problem with traditional staff development activities is that they tend to attract the best teachers, or the early adopters or innovators, who have already espoused technology innovation in their teaching" (2005, p. 914). An approach involving authentic contexts and situated learning experiences that lead to reflective practice is likely to be more transformative and sustainable.

Another successful method of disseminating educational technology research is that of peer-to-peer communication. Roberts points out that "early adopters may also assist in raising awareness and acceptance of the new technology by "spreading the word," providing demonstrations, sharing best practices, and possibly even serving as mentors or consultants to their peers, engaging in real time problem solving as difficulties or questions inevitably arise." (Roberts, 2008, p. 8).

Academics are overloaded by email, in their own silos – often unaware of external drivers - and are notoriously resistant to change (Bromage, 2006) as well as being entrenched in the traditional transmissive, individualistic, summative type of education. How can we effectively lead them through the array of possibilities to successfully change to teaching and learning for the future? How can we therefore make our communications processes timely, sustainable and at the same time get across the need for changing their learning and teaching approach not just doing what they've always done electronically and/or seeing technology as purely for administrative purposes? Sustainability, as Uys (2007) argues, "advocates true partnership between academic and support staff" (p. 15). Without this, as well as policy decision, it is hard to move traditionally conservative higher educational organisations to embrace technological change for learning and teaching rather than for operational effectiveness (Uys, 2007). There is also the need to make sure that "any initiatives designed to facilitate wider use of technologies for learning and teaching need to cater effectively for teaching staff at different stages of technology adoption (Uys, Dalgarno, Carlson, Crampton, Tinkler, 2011, p. 1267).

Background of the institutions

The University of New England (UNE), Australia

UNE is situated in NSW, Australia and was formed in 1938, becoming independent in 1954 (Bennett, 2009; Chick, 1992). There are approximately 18,000 students enrolled at UNE with more than 80% enrolled as off-campus students (Corporate Intelligence Unit, 2011). UNE, although a traditional university, has been a distance education provider since 1955 (Bennett, 2008). In the past, on-campus students experienced their learning through face-to-face lectures, tutorials, workshops and excursions, whilst off-campus students received their study materials in the mail through paper-based resources. In the 1980s this expanded to audio cassettes and, in the 1990s, multimedia CDs. Since 2000, UNE has been providing study resources through their Learning Management System (LMS) and is now providing almost all student learning resources fully online. The university has changed LMS several times in the past few years attempting to find the one that best suits the needs of their students and academics. Resources are provided through downloadable Portable Document Format (PDF), but they also utilise the affordances of the Internet provided through resources such as chat rooms, discussion boards, wikis, blogs social networking tools and virtual worlds.

The University of Canterbury (UC), New Zealand

UC, New Zealand's second university, was established in Christchurch city in 1873, and moved to its present site in Ilam in 1975. Approximately 12,000 students (UC, 2011) are enrolled across the six colleges/schools of the university. In 2007 New Zealand's second oldest teachers' training college, the Christchurch College of Education, which was established in 1877, merged with the university. The College of Education brought with it the Distance and Flexible Learning Options (FLO) which it had been offering students since 1995 as well as students in satellite campuses in Nelson, Tauranga, Rotorua and New Plymouth. Close to 60% of the College's 3,500 (UC, 2011) students are involved in the FLO program and all College of Education courses have an online presence through the LMS with the majority of courses being actively taught online, as well as on campus. The major earthquakes which began in September 2010 have encouraged an increase in the number of on-campus courses, throughout the university's other colleges, which also make use of the LMS. In February 2011 this increased significantly following the earthquake which closed the campus on the second day of semester one.

The University of Pretoria (UP), South Africa

While social and economic inequalities persist in post-colonial Africa, this country is the door to economic and other opportunities in Africa. Over the past 104 years, UP has become one of the largest residential universities in the country, with about 45,000 on-campus and 14,000 distance students (UP Strategic plan, 2011) spread over seven campuses. UP takes a leading academic institutional role, attracting students from the continent and further, particularly at post-graduate level. The diversity of programs continues into a diverse student and staff population, with focus on accommodating and developing human capital as much as increasing the post-graduate and international research footprint. The faculty of education offers post-graduate courses via paper-based distance education to mostly under-provisioned and under-qualified rural teachers. The rest of the university embraces a blended learning and teaching strategy combining lectures with LMS-delivered resources, activities, assessment, communication and more (Picciano, 2009). Currently about 2,000 subjects[1] have a presence on the LMS. More than 80% of students ((UP, 2011) as found in a recent unpublished survey) have web-enabled cell phones, and the use of other mobile devices is increasing. In response, the university recently launched the roll-out of wireless hotspots over the campus, being the first university in Africa to do this. One of the motivations to 'leapfrog' to mobile learning (m-learning) as an enhancement to contact teaching is to accommodate the students who do not have personal computers or Internet, and depend solely on on-campus computer facilities, to access the LMS. Unlike the other universities, new learning technology is mostly used to supplement lectures in a blended learning approach.

North-West University (NWU), South Africa

The NWU is a multi-campus university with the three campuses situated in two provinces. The Potchefstroom and Mafikeng Campuses are situated in the North-West Province and the Vaal Triangle Campus is in Gauteng. The university was established in 2004 with the merger of the Potchefstroom University for Christian Higher Education and the North-West University. The NWU's slogan "Innovation through diversity" describes the university precisely as the university is accepted as one of the best-managed and most innovative universities in South Africa. The university celebrates and encourages multiculturalism, multilingualism and multinationalism (NWU, 2011). As a multi-campus university, the students are offered a variety of choices, both academically and geographically. The three campuses collectively offer 15 faculties, which in turn offer more than 50 schools with currently 62,557 students enrolled (NWU, 2012). At the School of Continuing Teacher Education, the Interactive Whiteboard (IWB) sessions are used by the lecturers as a synchronous approach of contact with the students and facilitators. Learning materials are mainly paper-based, consisting of study guides, textbooks and a DVD containing additional information such as presentations and video footage. In line with current trends in the field of open distance learning, SCTE has started to implement the use of a LMS, IWB and m-learning to supplement paper-based learning materials.

Charles Sturt University (CSU), Australia

CSU is a multi-campus university with a large proportion of its students studying at a distance rather than on

[1] Many subjects (also known as units, modules or courses in various locations worldwide) contribute credits which make up a student's individual programme of study towards a degree or other qualification, (also known as their course).

campus. Specifically, in 2011 (CSU, 2011) 24,265 students were enrolled in distance mode, 9139 in on-campus mode and 5,003 in a mixture of on-campus and distance modes. In 2011 the University employed 784 full-time equivalent academic staff, in four faculties, as well as adjunct staff in a number of partner institutions within Australia and offshore. The University has required all subjects to have an online presence containing at least the subject outline and a discussion forum since the late 1990s, with online assignment submission available in all distance subjects since the early 2000s. An LMS was introduced in 2009, to increase student engagement and interaction via the provision of an announcements tool and a resource sharing tool in all subjects. Tools such as blogs, wikis and chat rooms were incorporated at the discretion of the academic. Since 2009 additional online educational technologies have been introduced increasing the move towards harnessing the social media, open and participative nature of Web 2.0 technologies.

Conducting and reporting on technology research

There are a variety of ways in which each institution has been conducting and reporting on technology research, which mostly centre on the availability of ICT and the LMS to students, and functionalities which add value to learning and teaching, and learning for the future. Collaborative research with academics consists of technology adoption case studies. Numerous departments provide small-scale ‘distance’ education programmes while flying under the banner of blended learning. These programmes provide excellent research material, acting as ‘laboratories’ to explore innovative teaching and learning approaches that respond well to an unique multicultural context.

Results of internal surveys are disseminated upwards to the stakeholders. For example, a task team that investigated a new computer-based testing system for high stakes assessment reported their findings in depth to a steering committee that had to make the final decision on which system to spend their resources on. Another example is an investigation into lecturing capture systems that was requested by the faculty which was reported back to that faculty’s deans and management structures.

Completed research comprised of Masters, PhD studies and research grants report their findings as dissertations, journal articles and contributions to conferences. Communication consists of reports and contributions at local and faculty research forums. After this level, a glass ceiling is reached where little information filters through to top management for policy making implementation.

Educational Designers (EDs) and Flexible Learning Advisors (FLAs), though not given research time, carry out ‘scholarly activity’ to keep up with their subject/domains of interest. Time allocation to concentrate on a particular educational technology or pedagogy allows them to lead knowledge and capability, that is then shared with others via professional development sessions. This way, an increase in knowledge about relevant learning, teaching topics, educational technologies and benefits from the collective and social constructivist advantages of being part of teams, is created and maintained. Such situations are opportunities to put forward relevant and appropriate aspects related to educational technologies and learning and teaching ’philosophy’ so that they can provide context, support and enthusiasm for academics around the ever changing world of educational technology. In some universities each school within a faculty has access to a dedicated ED/FLA who is physically located in that school. In other universities the number of EDs/FLAs is limited to a small number in a central location. A variety of ways of reporting on technology research occurs which can be loosely categorised into formal and informal style. Methods of communicating educational technology research have often been chosen to reach a particular audience.

Traditional formal reporting includes presenting at conferences bringing research to the attention of the institution. This approach tends to be generic and not discipline specific or applicable at an institutional level (Uys, et al., 2011). Likewise the usual reporting back through university committees is also conducted to a greater or lesser extent. The impact of this formal approach tends to be quite small, limited and lacks the ability for broader penetration.

A range of structured and organic communication processes has been implemented to augment the formal approach. Structured process can include: daily ‘What’s New’ university wide announcement; book club sharing of practice with prior reading of current research papers applied in practice; learning and teaching symposiums and an internal conference on Learning and Teaching; areas of professional focus where EDs/FLAs are specifically responsible for developing expertise around particular educational technologies; pilots of new technologies with champions and early adopters and road shows when university wide presentations are made around a specific topic or range of topics to raise them to the forefront of conversation. This structured communication is supported through a range of organic communication that centres on inclusive sharing and creating a collegiate environment. These organic groups include *Yammer*, an online social networking site and an ICT Community of Practice for sharing educational technology related practice. Further organic sharing of practice amongst EDs, FLAs and academic staff encourages continuous collaboration and collegiality.

Written forms of communication have been used. Reports are requested from management on new technologies, but information communicated in a report, is often too wordy for time poor academics to assimilate. Papers and posters published for conferences are seldom viewed by academics. Newsletters and emails containing information may be delivered to everyone, but they are not necessarily read. Courses have been created within the LMS to provide information on new technologies and educational design ideas. Staff have found this helpful, and tend to access the space when they are looking at making changes or thinking about trying something new (Tull & Brooker, 2009).

Planned events such as a university wide ‘Showcase’ or college level ‘Show and Tell’ have taken place, where academics share their use of educational technology alongside the ED/FLA who communicates pedagogical uses for new technology developments. Some universities hold a ‘Teaching Week’ to provide an opportunity to present to a wider audience. These events, more often than not, attract those academics that are already interested in, and looking for, innovation.

Attendance at department meetings and Learning and Teaching committee meetings has met with more success, partly because of a captive audience, but also because there is often more of an opportunity to ask questions in a less formal environment. Sometimes it has been possible for academics to see the technology in action to clarify their understanding of it. Group training sessions and workshops offer similar opportunities, but with the added advantage of being more ‘hands on’. Word of mouth, particularly from a colleague, appears to have the most impact across all institutions. Champions are supported and encouraged to work with others in their area. By far the most frequent method of communicating information on new technologies is through one-on-one sessions with academics. The informal session, which is most often focused around course design, provides the opportunity to discuss new methods and technologies.

The use of informal and formal communication methods stimulates conversations about educational technology challenges and opportunities within schools, faculties and the wider institutional context. EDs/FLAs are integral to this conversation and are able to participate in a wide variety of areas that includes school boards, learning and teaching committees, meetings, forums, professional development planning and delivery, morning tea, corridor exchanges and other groups/forums, on demand. These constitute a wide variety of opportunities to provide both leadership and support of leaders in implementing change.

Table 1 shows an aggregation of the known communication methods used by the authors’ institutions. These methods have been categorised according to Keller’s ARCS framework for motivation (1987). The wide variety of methods is spread across all levels of motivation and the majority of methods are common to all institutions.

Table 1: Comparison of reporting approaches from our institutions

Challenge	Intended Audience	Approach	Institution
Drawing Attention	Leaders	Reports	UC, CSU, UP, UNE, NWU
	EDFLAs[2] Academics	Papers	UC, CSU, UNE, NWU
	ED/FLAs, Academics	Posters	UC, CSU, UNE, NWU
	ED/FLAs, Academics	Community of Practice	CSU, UP, UNE, NWU
	ED/FLAs, Academics	Book Club/Writer's Groups	CSU, UNE
	ED/FLAs, Academics	Daily Announcements	CSU, UNE
	ED/FLAs, Academics	Showcase & Road shows	UC, CSU, UP, UNE, NWU
	ED/FLAs, Academics	Show & Tell	UC, CSU, UP, UNE, NWU
	ED/FLAs, Academics	Teaching Week	UC, UP
	ED/FLAs, Academics	Emails	UC, CSU, UP, UNE, NWU
Demonstrating Relevance	ED/FLAs, Academics	Learning & Teaching Committee Meetings	UC, CSU, UP, UNE, NWU
	Academics	Department Meetings	UC, CSU, UP, UNE, NWU
	Academics	Online examples e-learning space	UC, CSU, UP, UNE, NWU
	Academics	Champions in department	UC, CSU, UP, UNE, NWU
	Academics	Group training sessions	UC, CSU, UP, UNE, NWU
Developing Confidence	Academics	Workshops	UC, CSU, UP, UNE, NWU
	Academics	Drop-in sessions	UC, CSU, UNE
	Academics	Online documentation	UC, CSU, UP, UNE, NWU
	Academics	One-to-one consultations	UC, CSU, UP, UNE, NWU
	Academics	Formal Qualifications (Grad Cert)	UC, CSU, UNE
Developing Satisfaction	Academics	Mini grants	UC, CSU, UNE, NWU
	Academics	Improved teaching	UC, CSU, UP, UNE, NWU
	Academics	Education Innovation Awards	UC, CSU, UP, UNE, NWU
	Academics	Professional development portfolio for promotion	UP, UNE, NWU

Defining our audience, issues and constraints faced

As context is critical for communication, which is rarely carried out in a neutral environment, we need to target audiences in different ways for maximum effect when reporting on educational technology to support or lead change. For comparison purposes, therefore, we divided our audience into three categories; leaders, EDs/FLAs and academics (see Table 1). We further decomposed these headings to include the type of information our audience might need (see Figure 1), including; leaders who make strategic decisions and must focus on implementation relying on information we provide about resourcing and costs, EDs/FLAs, focusing on support are looking for information about features and functionality and academic staff that need to buy-in unequivocally as the users of new technology need information on how to apply the technology, as well as the potential barriers to overcome.

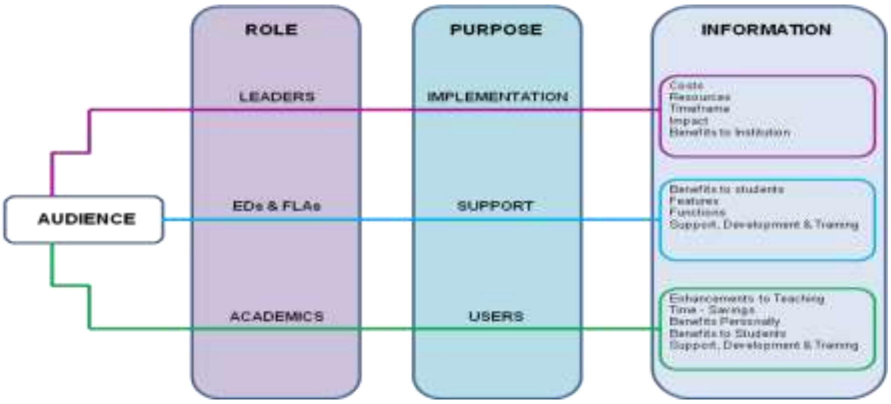

Figure 1: Who is our audience?

Leaders

One of the major barriers to communicating the latest educational technologies can be senior management within faculties and schools as well as within the senior management of the university as a whole. Their potential lack of buy-in or the low priority given to new tools or ways of doing things can have a seriously detrimental effect on the implementation of change around technology. Additionally without careful timing of messages and new

[2] As different names are used for similar roles across worldwide locations for the purposes of this table we have used Educational Designer (ED), and Flexible Learning Advisors (FLAs)

information, EDs/FLAs can be seen as creating a problem with academics rather than providing a solution. In this climate of constant change, if leaders are shown the features and benefits of technology before they are ready, regardless of the advantages of that specific tool or pedagogy, it is unlikely they will buy in to it.

Educational Designers or Flexible Learning Advisors

As a still relatively new and emerging profession EDs and FLAs come from a range of backgrounds that are either more or less focused on education or technology. ED/FLAs were traditionally paper focused and often seen as proofreaders and editors with high journalistic skills. Working directly with academics on specific subjects they were often involved in the presentation of content above all else. Now, more commonly, EDs/FLAs have a range of higher level curriculum review process and project management abilities along with educational and information systems backgrounds. These combined abilities, coupled with their ability to work collaboratively, (a must in the information age) situate them as change agents for introducing, supporting and implementing new educational technologies. A key requirement is to enable academics to build capability and sustainability whilst at the same time putting in place the strategies that senior management want across the institution. Over and above all the EDs/FLAs must be change agents and culture shifters.

Academic Staff

The rate of educational change is fast moving and constantly changing. Whilst EDs/FLAs are accepting that 'the only constant is change', this is not necessarily the case for academics. The academic propensity to work alone, to need time and space to formulate ideas (Bromage, 2006), coupled with research being high on the agenda, related to performance management are perceived by academics as critical to their career means that (often as a survival strategy), learning and teaching is pushed down the agenda. The perception (real or otherwise) of lack of provision of time to embrace new educational technologies for subject design and development adds weight to this. What is vital then is to concentrate on communicating the 'benefits' of technologies, in a timely way, in this educational revolution, to teaching staff whilst at the same time making explicit the support mechanisms and very real help and support that can be provided.

What are the issues and constraints?

In developing communications reporting technologies to others in our institutions, there are a number of issues or constraints to be considered so that appropriate changes can be suggested.

Internet Connections

Insufficient Internet access can be seen as one of the major reasons contributing to the failure of the realisation of the potential of e-learning in open distance education in many contexts (Ololube, Ubogu, & Egbezor, 2007). Insufficient Internet speed limits the technologies that can be utilised, particularly those which deliver multimedia content, while excessive taxation of ICT goods and services keep these inequalities entrenched.

Student Diversity

Teaching and learning with technology is often hampered by technological and social inequalities. Many students are multicultural, multilingual, with diverse levels of skills and knowledge, like insufficient reading and writing skills. Other challenges such as the diversity of students in terms of age, gender, language use, culture and living in deep rural areas are at the root of learning inequalities. In order to overcome these challenges a palette of learning technologies to address learning inequalities in an open distance learning environment is used.

Access

M-learning may provide a solution to the challenge of access to the Internet, as the scale and ubiquity of mobile networks often provide the only infrastructure in rural areas (GSMA, 2010). M-learning using these networks offers exciting opportunities to optimise communication between lecturers, facilitators and learners as it offers learning opportunities to rural or remote learners without the necessary infrastructure for conventional access to the Internet (Evans, 2008). As communication and interaction are of pivotal importance in the learning process, m-learning can contribute towards the quality of education. M-learning has all the advantages of e-learning, with the added benefit of portability in the form of devices such as iPods, iPads, tablet PCs and smart phones (Evans, 2008). The challenge for lecturers lies in embracing the strengths of mobile devices and design learning materials that utilise the convenience, connectivity and personalisation that such a platform offer (Griffen, Mitchell, & Thompson, 2009). The 2012 Horizon report states that tablet computing presents affordable learning opportunities (Johnson & Brown, 2012). The advances of tablet computing with a growing number of features are ideal for one-to-one learning. It also reports that the Zimbabwean government, in partnership with Apple, are planning to bring solar-powered iPad devices to rural institutions without electricity (Johnson & Brown, 2012). South-African institutions should learn from this example and invest in the use of m-learning to address the connection challenges of students. This implies that, with the increased use of mobile and wireless technologies, "the time and place for learning, working, and socialising will blur even more" (Bonk, Kim, & Zeng, 2006 (p. 561). An important implication is that mobile and wireless technologies may create greater opportunities for lifelong learning as learning will be more accessible to a wider range of individuals (Bonk, et al., 2006).

Strategic Alignment

Barriers to incorporation of technology are on all levels, from government policy that limits distance learning to certain institutions, the University's strategic plan, infrastructure, the profile of the student's entrenched social and other inequalities. When the primary focus of a University is to increase its international ranking as a research institution, it can affect innovative teaching with technology. Further barriers to improved teaching are promotions and government subsidies for research outputs.

None of the top down approaches has been found to be very successful. Important information regarding retraining and redesigning for the upgrade of a LMS are often poorly disseminated through the official faculty structures because the people in charge are not the people on the ground and, they have different priorities. From the bottom up, EDs/FLAs communicate and advise in workshops and on a one-on-one base with lecturers who seek out their services. Emails are also sent from the LMS to lecturers and other staff who have a presence there. A middle-out approach is used to get all the EDs/FLAs on the same page, for instance in preparing to implement a new technology institution-wide.

Financial

Across the sector there are restricted funds for implementing new technologies or giving existing staff time off from regular activities to pursue new avenues. The particular difficulty for EDs is that they are not given time to explore new developments nor are their performance management targets related to research in any way to motivate such exploration. In addition, the research life cycle can often be slow in relation to the emergence of a new educational technology lifecycle.

Change management and institutional impact

The pervasive use of educational technology in higher education has made it imperative to understand what the critical issues are when implementing enterprise wide learning strategies to support a digitally enhanced learning environment. Managing change for enterprise-wide impact in higher education in particular is problematic since people are central to the process, and it is therefore necessary. Fullan (1991, p. 350) suggests, "… we explicitly think and worry about the change process" in educational reform.

To ensure institutional impact, when creating sustainability, the situation turns to the challenge of maintaining interest and motivation towards embracing new ideas and technologies. The problem then is how to keep on an academic's radar, how to gain their attention and take interest in what you are reporting to them. Kotter (1996) states that to lead change and gain buy in from necessary stakeholders senior leaders must create 'a sense of urgency'. This does not happen naturally, it comes from people who have the motivation to get things done. He further states that for change to be successful, 75% of an organisation needs to change. His view is that, when there is a disconnect between the internal organisation and external environment, or where there has been 'success' complacency occurs, which leads to inaction.

How do we communicate, to connect?

Having explored the issues and constraints when conducting and reporting on educational technology research for institutional impact, we now examine communication strategies to help connect with our different audiences in leading or supporting change.

Communicating with Leaders

Experience with specific project proposals shows that it is useful to create multiple documents that drill down into the detail. With complex papers and proposals there is a need to simplify the detail and the message. Detailed documents may not be the best way to present the information. What works better is to create the detailed document and then distil it into one containing one sentence answers addressing: who, what, where, when, why and how much. This is critical for senior management, who prefer knowing that you have addressed the relevant aspects, to having all the details. Speak directly to the leaders. Committees can sometimes interpret and misinterpret your information so going directly can save time and hassle. Offer to present. It is quicker and can have more impact than reading a paper.

Communicating with Academic Staff

Timeliness and workload is the critical factor when communicating to academic staff. They will ask “What is the relevance of this ‘new’ educational technology right now to me as I work through the academic year? Do I have the time to adopt it and will it save me time if I do?” Affordances and pedagogical considerations are often deferred until the end of semester and/or additional resources in terms of time with EDs/FLAs. Often it requires one-to-one support and sharing of practice with another academic to truly buy in to the technology.

Communicating with Educational Designers

Communication at this level tends to be much less formal. Physical proximity may make face to face discussions and impromptu demonstrations of newly discovered technologies possible. Social media sites such as Yammer or Google+ can be used to share information found on the Internet with those who are more distant, or who prefer written communication. Email is often used to pass on information received in this same format. In communicating with this group too though, there are opportunities to share within a more formal presentation, information that has been gathered from conferences or workshops, as well as research undertaken. Affordances, features, benefits and pedagogical relevance are crucial issue to engage EDs/FLAs. Once these are established they are able to ‘transfer technology’ and disseminate both the ‘why’ and ‘how to’ to other audiences.

From reflections on experiences in presenting to different audiences some general communication recommendations emerge regardless of the technology being presented or the mode of presentation. For the purposes of clarity the principles are identified in brief with a fuller explanation (see Table 1) for which the communication channel is most apt.

Table 2: Recommended Communication Channels for our Different Audiences

Principle	Explanation
Be clear	Technology can be complicated so clarity is key. If you cannot sum your main points up in a few sentences your audience will not grasp it.
Illustrate your point	‘A picture speaks a thousand words’ and can often explain complex concepts quickly and easily. Use diagrams, visualisations, mock-ups, personas and analogies to help convey key ideas and contexts.
Simplify complexity into something tangible	Do not get bogged down in detail. Most people do not want to read it but they do want to know you have researched it. Technicalities get in the way of the message. Use appendices, attachments or links to more information.
Create a conversation	Connect with your audience and create a space for questions, answers and contextualisation through a conversation. Creating a dialogue allows the information to flow and allows you to clarify your points or relate it to a specific audience.
Get to the point	Shape your information to be like a pyramid with focused findings at the top and the details at the bottom. This shows the construction of your work with a stable foundation is key
Present your information	With our audience becoming increasingly time poor it is useful to note that it is quicker to listen than to read especially for a large audience. Think mathematically - (time to read paper) x (number of audience) – 1 hour to read x 100 people = 100 hours on your paper.

Conclusion and summary

From the literature reviewed, and examination of the approaches employed within our different organisations, when conducting and reporting on educational technology for institutional impact it is essential to adopt appropriate styles of communication and reporting mechanisms for our different target audiences. In an environment of constant change, specifically targeting our identified audiences with the right media of the message, as well as choosing the right type of messenger is crucial to drawing attention, demonstrating relevance, developing confidence and developing satisfaction. Additionally, we must take into consideration what particular stage of technology adoption our audience is at. If we can get these things right, we can at last lead a change from technology in education being traditionally driven by efficiency and administrative purposes towards truly embracing technology for effective enhancement of the student experience and genuine learning activities and opportunities.

What we can see from reviewing the literature and examining how we approach conducting and reporting on educational research to our target audiences is that across each of the institutions we have all adopted a range of methods to reach the different audiences we serve that follows current thinking in this area. Are we making it explicit to our audiences that the different approaches we adopt are for different reasons (attention, relevance, confidence, satisfaction)? However, whilst there is clear formal research and focused research, an area that could be developed is examination of just how successful those different audiences found those different approaches presented by EDs/FLAs in particular. To gain feedback from those different voices would add a new dimension to our understanding of how to disseminate educational technology research with impact, in this climate of change.

Implementation of the eLearning Lifecycle Model to Develop Reflection in Pre-Service Teachers

Pauline Roberts
School of Education
Murdoch University

Dorit Maor
School of Education
Murdoch University

This paper outlines the planned research into the use of an ePortfolio Environment to support the development of reflection in pre-service teachers. Reflection is a key skill for teachers to possess as they continue to learn into the future. It is a doctoral research project that involves the implementation of sections of the eLearning Lifecycle model (Phillips, Kennedy, & McNaught, 2011) within a PebblePad platform. The proposed environment will include examples, activities and interactions as part of an Enculturation Teaching Model (Tishman, Jay, & Perkins, 1993). The impetus for the activities will be the sections of the Framework for Teacher Reflection (Colton & Sparks-Langer, 1993). The implementation aims to develop a teaching environment that can be used in a variety of platforms to develop reflective abilities in pre-service teachers that will be used for continued professional development.
Keywords: ePortfolio, Reflection, eLearning Teaching Models, Pre-Service Teachers.

Introduction

This doctoral research project developed from experience in working with pre-service teachers and the difficulty faced in developing reflection with these students. The study aims to identify a framework using an electronic learning platform that will assist in the development of reflection in pre-service teachers. The research proposes to utilize the PebblePad ePorfolio to scaffold the students' development of reflection. PebblePad was selected because it had been used in the action-learning project unit previously. The eLearning Lifecycle model developed by Phillips, McNaught and Kennedy (2011) was chosen as it follows a cyclic implementation with a structured framework for review and ongoing improvement tailored to an eLearning environment. The structure of the PebblePad ePortfolio and the experience of the researcher within the teaching unit meant an adapted implementation of the lifecycle could be planned.

Within the eLearning environment, an enculturation teaching model (Tishman, Jay & Perkins, 1993) is used to provide (1) examples of good practice (2) activity prompts to teach reflection and (3) a platform within which the students can interact with one another. This teaching model was originally developed to increase higher level thinking skills or the dispositions of thinkers and can be transferred to reflection, which also requires the use of metacognitive strategies.

As part of this teaching model, the planned activity prompts were taken from the areas of the Framework for Teacher Reflection (Colton & Sparks-Langer, 1993) that encompasses many components of reflective practice. It is anticipated that this model will provide the foundation for the activities and ensure there is a strong theoretical base for the prompts.

The overall goal of the research is to develop an outline of an effective electronic teaching environment that concentrates on the development of reflection in pre-service teachers. The outline may be transferrable to other ePortfolio teaching platforms and perhaps even other content or skill areas beyond reflection.

Literature Review

The literature for this project comes from two key areas that are very briefly outlined here. The first is reflection, its importance in education, and the methods trialled to develop it. The second is the area of ePortfolio in terms of providing a teaching environment within which to develop these reflective abilities.

Reflection

Reflection has been identified as being important in education because in the future, "schools will be restructured communities of learning requiring empowered, [and] reflective decision makers" (Colton & Sparks-Langer, 1993, p. 45). With the rapidly changing global climate, there is a need for lifelong learners who are able to reflect on their abilities and make changes with these times (Yost, Sentner, & Forlenza-Bailey, 2000) and continue to learn into the future based on these experiences.

In a conceptual review of reflection in higher education, Rogers (2001) identified a number of key common theoretical factors that emerged from the authors of reflection. These included a clear understanding of the terms being used in relation to the general definition, the timing and the context; the outline of the antecedents; the contextual factors; the definitional component; the process; the methods and the desired outcomes of the process (Rogers, 2001). These factors need to be clearly outlined to all stakeholders involved in the development of reflection in any given context to ensure a shared understanding of the concept and the process.

The Framework for Teacher Reflection (Colton & Sparks-Langer, 1993) provides a model from which all of these theoretical factors can be identified. The model is divided into three sections that focus on (1) action in terms of an action research style of approach to developing reflection; (2) constructing knowledge and meaning in relation to choosing an area of focus and discussing this with others and; (3) the professional knowledge base that consists of the background of the reflection and the context in which it occurs. The model also identifies attributes of reflective thinkers, which lead to the identification of the proposed enculturation teaching model.

For this planned research, the reflection by the students is completed as part of an action-learning project. The aim of the project is to encourage reflection that Dewey (1933, p. 9) defines as "active, persistent, and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and further conclusions which it tends". The goal is to move beyond the recording of events *after* the incident (reflection that Schon describes as *on-action*) to taking action at the time of the 'surprise' to make a positive change to practice (reflection *in-action*) (Schön, 1995, p. 30). The students' projects are implemented in a practical situation with the issue of focus being chosen by the students based on previous experience within the classroom and should follow cycles of action research (Grundy, 1995).

The overall aim of the action-learning project is to not only improve the students' abilities within their chosen area of practice but to also provide experience with the process of action research and reflection as a catalyst for ongoing professional development. The recent development in electronic portfolios provides the option to use them in teaching environments and includes another component of the standards required by the Accreditation of Initial Teacher Education, being the use of technology.

ePortfolio

The use of electronic portfolios or ePortfolios has increased recently, due largely to government policies (particularly in the United Kingdom) requiring their use (Clark & Eynon, 2009; Joyes, Gray, & Hartnell-Young, 2009; McAllister, Hallam, & Harper, 2008). An ePortfolio is "a collection of authentic and diverse evidence, drawn from a larger archive representing what a person or organization has learned over time on which the person or organization has reflected, and designed for presentation to one or more audiences for a particular rhetorical purpose" (Barrett, 2005, p. 5). This definition immediately identifies that a person may have several levels of an ePortfolio from a working document to a presentation portfolio (Pellicione, Dixon, & Giddings, 2005) that is adapted to meet different purposes (Clark & Eynon, 2009).

Joyes et al. (2009, p. 487) provide a useful extension to this description by adding that "behind any product, or presentation, lie rich and complex processes of planning, synthesising, sharing, discussing, reflecting, giving, receiving and responding to feedback." The authors go on to discuss that these processes make up ePortfolio-based learning which is receiving increased attention from the Joint Information Systems Committee (JISC) that works with colleges throughout the UK in digital technologies (Joyes et al., 2009). It is this learning process that is the feature of the ePortfolio that led to it's use in this planned research.

Dr Helen Barrett, who has been labelled the "grandmother of ePortfolios" (Barrett, 2010), advocates that ePortfolios be utilized as learning tools. In her 2005 white paper, Barrett highlights the processes of learning and assessment involved in an ePortfolio and proposes that the technology is now available to "engage students in active participation" and reflection through "assessing and managing their own learning" (Barrett, 2005, p. 23). There are a number of commercial platforms available for ePortfolios and many have self-directed help packages within them that guide the learner through the process (Pinney & Edwards, 2007). This structured support is important in the development of reflection (Lamont, 2007). The platform of PebblePad has been shown to be user friendly and to allow for communication with others (Pinney & Edwards, 2007). It has also been demonstrated to play a significant role in the development of reflection when implemented with ongoing support (Bloxham, Boyle, & Thanaraj, 2009). This then provides a strong base for further research.

The Research Outline

The planned research will involve the implementation of sections of the eLearning Lifecycle Model developed by (Phillips et al., 2011). The cycles of this model are designed to develop and evaluate electronic learning environments based on the principles of action (McNiff & Whitehead, 2006) and design-based research (Hoadley, 2004). The process involves the implementation and review of the environment to make improvements with each iteration. This project proposes to use the model from Cycle 3, the trialling of the environment through one review at Cycle 4, followed by recommendations being made for practice as part of Cycle 5 (Phillips et al., 2011).

Within the eLearning environment the execution is based on the enculturation teaching model (Tishman et al., 1993) and the framework for reflective teachers (Colton & Sparks-Langer, 1993). Figure 1 shows the relationship of these components within the research. The overall implementation of the case study is planned within the cycles of the eLearning lifecycle (Phillips et al., 2011). The PebblePad platform has a "Gateway Resources" facility that provides a platform within which the teaching model can be realised. Within the resources, the students can be provided with access to (1) examples of good practice (2) prompts or activities aimed at the components of reflective thinking and writing and (3) a space where comments and interactions about this process can be shared (Tishman et al., 1993). The planned prompts and examples are based on research into the development of reflection that can be placed within the components of the Colton and Sparks-Langer (1993) framework for teacher reflection.

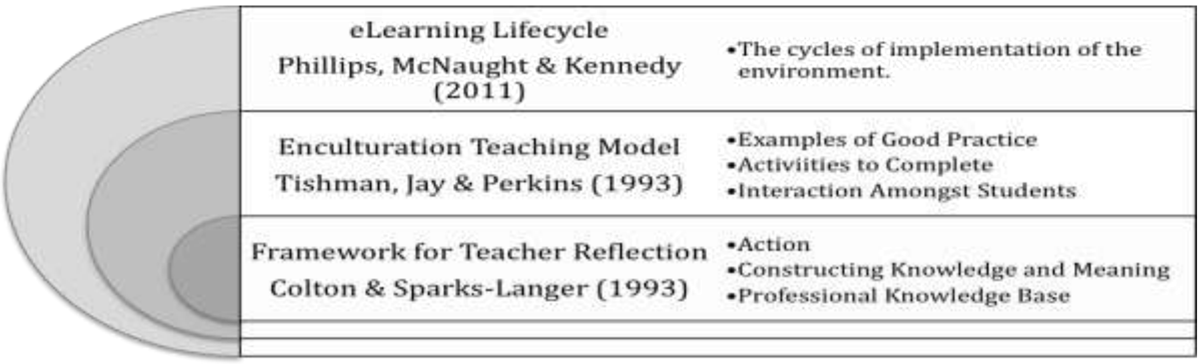

Figure 1: Relationship of Research Components

The choice of these models and frameworks came from experience with the teaching platform with previous groups of students and the understanding that a strong theoretical base was required in the planning of the prompts. In the past, the students remained very focused on the use of the platform as an assessment tool rather than a vehicle for the development of reflection (Roberts & Maor, 2012).

Data will be collected using a mixed methods approach including feedback questions on each of the prompts, interviews and learning analytics as detailed below:

- a set of questions will accompany each activity prompt to identify whether the task was useful and if so why. The students will be asked to answer these as a blog reply.
- interviews will ask the students about their experiences with the environment. The focus group interview environment is planned to allow students to encourage each other and provide a range of viewpoints on the PebblePad environment. The individual interviews will be more focused and use examples of each students writing as the basis for questions as well as allowing comparison of student's responses to log data generated within the PebblePad platform that identifies the students' usage patterns.
- learning analytics will be used to evaluate possible links between levels of reflective writing and engagement determined by usage log data from within PebblePad. This numerical data may add to the details from the interviews about the use of the prompts within the environment.

The implementation and data collection for this research will occur within 2012 with final reporting planned for early 2013.

Proposed Outcomes

The outcomes of this research for practitioners will be a better understanding of how to scaffold pre-service teachers to reflect through an ePortfolio environment. This will include methodologies of action research, strategies to engage the students in reflective discussions, and formats to demonstrate reflective abilities.

The principles of the ePortfolio environment identified in the research may also be transferable to other platforms to expand the use of ePortfolio as a teaching and learning tool. In terms of theory, the research will add the layer of the learning environment to existing framework for reflection developed by Colton and Sparks-Langer (1993); provide the context identified as required by Rogers (2001) and add to the knowledge of ePortfolio-based learning environments as discussed by Joyes, Gray and Hartnell-Young (2009).

Reflections on staff development in eLearning via a community of practice model

Tabitha Roder
Te Puna Ako – eLearning academic development
Unitec Institute of Technology

Nicoletta Rata-Skudder
Faculty of Social and Health Sciences
Unitec Institute of Technology

This narrative seeks to identify practices which have enabled staff in eLearning roles to support their peers to increase the use of eLearning within a New Zealand tertiary education context. Specifically, it examines those factors which have contributed to the development of institutional capability in eLearning over a two-year funded period. Unitec New Zealand has recently implemented a transformative eLearning Development Strategy with the aim of developing the capability and capacity of Unitec academic staff in integrating learning technologies. The funding of a number of temporary roles aided development of staff capability and capacity in eLearning through a Community of Practice model. We consider factors that contribute to the development of a sustainable learning culture, and identify how a community approach has enabled this. We further explore and reflect upon the enablers and barriers experienced in the eLearning roles, and the implications of using this model and its efficacy in meeting institutional goals. An extended version of this paper was presented at the Moodle Research Conference held in Heraklion, Crete on 14-15 September 2012.

Keywords: eLearning, capacity building, staff development, Community of Practice, tertiary, New Zealand

Background

Unitec provides vocational and applied professional education from Certificate to Doctoral level at it's four Auckland campuses, with mostly face to face courses, however there is an increasing demand for more flexible delivery of courses. Oram's (2009) Auckland 2060 report forecasts a climate of change requiring teaching practice to be reconsidered to reflect the societal demands of the future. In 2010 Unitec began implementation of a transformative initiative described as the Living Curriculum. This entails a number of key principles including complex conversations, curiosity, focus on practice, social constructivism, blended learning experiences, research-informed, interdisciplinary, literacies for lifelong learning and embedded assessment. Underlying this, an additional 'eLearning Development Strategy' was launched with the aim of developing the capability and capacity of Unitec academic staff in integrating learning technologies to enhance the learning experience offered to Unitec students. It was recognised that in order to fully integrate eLearning into the Living Curricula, institutional capability had to be developed and support structures provided to facilitate development activities. As a vehicle for realising these objectives, the Community of Practice (CoP) model was selected as a potentially empowering approach to building social capital.

Communities of Practice

Wenger (2006) defines communities of practice as "groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly". The Community of Practice model was selected with the aim to facilitate staff capacity building partly because it presented the opportunity for the practitioner to adopt the role of both expert and learner within the Community. This is of particular significance given the nature of the Living Curricula, and in questioning the traditional role and identity of academic staff as experts rather than life-long learners and collaborative constructors within the domain (Keesing-Styles & Ayres, 2011). This approach is also more fitting with ‘Ako’, the Māori concept of teaching and learning as a reciprocal, connected and interrelated process “where the educator is also learning from the student and where educators’ practices are informed by the latest research and are both deliberate and reflective. Ako recognises that the learner and whānau [family community] cannot be separated”. (Ka Hikitia, 2008, p.20)

Additionally, the Community of Practice model is one which is said to offer a “demanding and productive perspective” (Wenger, 2009) from which to view the relationship between community and technology. In understanding how technologies can influence, challenge, foster and be adapted by communities, participants are afforded the opportunity also to experience and reflect on the implications of eLearning as framed within the Living Curriculum.

Funded Roles to support eLearning Strategy rollout

Unitec leadership recognised that the implementation of the eLearning Strategy, Living Curricula and transition from Blackboard to Moodle, would present staff with some confronting change. It was acknowledged that staff would need time and support to enable an optimal response to the new demands being posed. The success of the eLearning Strategy therefore was dependent on strong support within departments and central support teams, to ensure staff had adequate scaffolding for the change process. “Teacher’s capacity for change is frequently compromised by issues of workload, and a significant ongoing challenge was enabling processes whereby workloads could be managed effectively to allow the time and space for conversation and reflection.” (Keesing-Styles & Ayres, 2011 p. 50).

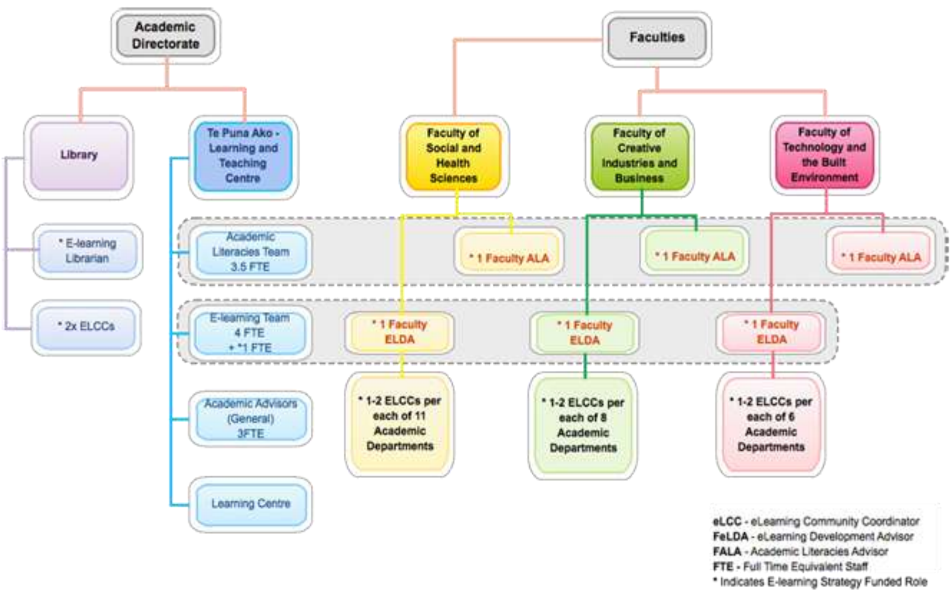

Figure 1: Roles supporting staff development in eLearning during the eLearning Strategy Implementation

Unitec leadership recognised the key value of providing well-resourced support services in enabling the pedagogical shift and technical skills acquisition required to successfully implement the eLearning Strategy, as “support allows those engaged in the difficult process of implementation to tolerate the anxiety of occasional failures” (Guskey, 2002, p. 388). Provision of support under the eLearning Strategy involved both centralised and faculty-based resourcing. The eLearning Strategy was driven through Te Puna Ako, the learning and teaching development centre. The Centre provided dedicated expert support for staff in eLearning (including technical support in partnership with IT services), general academic support, and support in the integration of literacies. The Te Puna Ako Learning Centre provided academic support to students. A number of additional, temporary roles were funded to support and foster increased staff capability and capacity in eLearning and associated academic and information literacies. A supplementary eLearning team member was employed in Te Puna Ako for the duration of the eLearning Strategy roll-out. Additionally, one full time eLearning Librarian role, three full time Faculty eLearning Development Advisors (FeLDAs) and three Faculty Academic Literacy Advisors (FALAs) were recruited to complement the department-based eLearning Community Coordinators (eLCCs) and to work closely with Te Puna Ako.

These additional roles were initially deployed for 18 months. The department-based eLearning Community Coordinator (eLCC) roles were a part-time appointment filled by existing Unitec teaching staff, who were each given (up to 0.2) time release to provide staff development opportunities within their department.

> "The CoP model has been a key vehicle for facilitating collaboration within and across departments, as has the funding of specific 'technology stewards' (eLCCs) within the departments. These eLCCs are vital shaping voices in helping keep the focus and purpose of eLearning developments on core pedagogic issues." Keesing-Styles and Ayres (2011)

The FeLDA's and FALA's assisted in liaising with and supporting the various departments in Unitec, and supporting the Communities of Practice. The initiatives driven by the Library impacted on institution-wide adoption of eLearning, assisting in embedding information literacy through technology, building capacity, and providing access to resources and equipment.

Community of Practice Implementation

In 2010 official implementation of the CoP approach was launched with a five day workshop facilitated by Etienne Wenger & Beverly Trayner. The workshop set the stage for the eLearning community in establishing an identity, defining roles and initiating the eLearning Strategy at Unitec.

> "The first organised event most of the eLCCs attended was the week-long Community of Practice workshop with Etienne Wenger and Bev Trayner. I cannot emphasise enough how important and meaningful this event was for me. Wenger and Trayner provided the eLCC group with an important introduction into community of practice theory and practice, and eLCCs spent the week conversing, bonding and learning. We entered as individuals and exited as a community. As far as I'm concerned, the organisation of that workshop was a stroke of genius." (eLCC quoted in Benseman, 2011, p. 8)

The eLCCs had regular informal and formal events together, workshops, regular mini symposiums where they shared what they were doing, shared knowledge, and talked together about the challenges they were facing. These opportunities were utilised more by the active eLCCs and those who had time available. Some eLCCs also ran a similar CoP within their department, but tailored to their departmental needs. The eLearning team modelled the role of "technology stewards" (Wenger, White & Smith, 2009), encouraging interdepartmental interactions and sharing of best practice. This coaching from the eLearning team assisted eLCCs to support their CoP's as they were established and shaped to meet each department's needs. The use of Moodle Docs, Moodle tracker, and forums supplemented the internal support. Participants of the eLearning CoP also contributed in wider Moodle community activities.

Identified Issues

A mid-point survey and end point interviews of eLCCs were conducted in the eLearning Strategy implementation period. Several themes emerged from this data, which are useful in informing an evaluation of the efficacy of the approach taken, and in reflecting on those factors which had impacted on the eLCCs ability to foster staff development. Evidence is also drawn from the Strategy evaluation and evaluation moderation documentation.

Time and Workload

Time and workload were highlighted as the most significant barriers to participation in the eLCC community, and in fostering community and staff development within the Departments. "Many staff are keen to learn more and get involved - but the opportunity to do so is limited by staff and eLCC's time, free meeting "slots" and similar resourcing issues" (eLCC).

Allocated time to participate in Community activities was seen as a crucial enabler. "Having an official role and time release within my department allowed me to greatly expand the eLearning support I had previously been unofficially providing to staff in my department. It enabled me to have individual discussions with each of my colleagues and provide them customised support to achieve their eLearning goals." (eLCC)

Digital Literacy

Digital literacy levels of staff impacted on the uptake of eLearning technologies and their ability to recognise the pedagogical affordances of these technologies. There were many staff requesting Moodle basic tools workshops who were simply not ready to discuss Living Curriculum characteristics or the eLearning Strategy as they did not feel confident using online technologies. The Natural Sciences department found the collaborative design and use of a Moodle course template alleviated some of the barriers related to literacy issues for their staff.

Support

Midpoint and endpoint feedback accorded with the Unitec leadership's acknowledgement that support systems would be crucial to the implementation of the eLearning Strategy. From the eLCC perspective particularly, the value of local (within Departments) and central support services, and conversely, the detrimental impact of a lack of support were perceived as crucial determiners in enabling both community and staff development to flourish.

Central Support

The integral role Te Puna Ako played in staff development was frequently recognised, both for the provision of practical training and advice, and for the interpersonal support and connections. The support activities offered by Te Puna Ako were highly valued, with one on one training and mentoring rated by eLCCs as the most useful support received. The value of face-to-face communication with Te Puna Ako was also highlighted. "TPA staff are our hub to go to. It is excellent to be able to drop in anytime and have face to face contact" (eLCC). eLCCs ranked the Te Puna Ako mini symposiums in particular as being 'highly useful' in supporting the eLCC role. "I learnt a lot, met so many people, very friendly and approachable lot at TPA, exchange of experiences, friendly atmosphere, love the homemade cakes" (eLCC). Activities facilitated through the central support teams provided important opportunities for sharing knowledge and keeping momentum.

> "The eLearning communities' mini symposiums were great as you got to see how web 2.0 tools could be utilised in teaching in a way that I could understand and hear staff talking about successes they were having, so I could then see scope for being innovative and creative in teaching, and TPA provided a great space for that to happen with an inclusive open flow through feeling about it". (eLCC)

Many of the eLCCs requested more opportunities to share best practice in the existing format of TPA sponsored mini symposiums, though equally there was a desire for tools based workshops, highlighting the need to consider digital literacy levels for these key staff. "I have found that when I need to do a specific thing in eLearning that specific consultation is very helpful." (eLCC)

Local Support

It was concerning that one quarter of the eLCCs felt they received 'little or no support' from within their department. The majority met with their Head of Department monthly or less and were more likely to met with Te Puna Ako staff. One eLCC wrote that "without active support and championing within a Department's management and leadership structure it is difficult to get traction."

Strong local support greatly enhances the chances of successful staff development. In the Department of Languages there was strong leadership support, evident in the provision of additional, department funded e-learning leadership roles to support the work of the eLCCs. This department had very active eLCCs who took were proactive in enhancing their own capability and sharing their learning and experiences, in the Department CoP and National Moodle Moot for example. There was recognition of successes within the department and ongoing dissemination of the learned expertise across the department. Many staff development activities were initiated in this department, including well patronised forum conversations, 'social' eLearning events and a variety of workshops. This department integrated a number of additional web 2.0 technologies and worked with the eLearning team to identify discipline specific Moodle modules and plugins that supported their students to meet learning outcomes.

Role Ambiguity

A lack of clarity of the eLearning roles may have impacted on their efficacy and on the way in which the roles were received and perceived by other staff. This ambiguity appears to have resulted in part from the tension between the organic and dynamic nature of roles within a CoP, and the management and peer expectations of a paid role in achieving specific outcomes in a given timeframe. Roles within a Community of Practice are by necessity fluid, allowing for participants to in turn offer their unique perspectives, experiences and expertise. Scope exists within the CoP model to appreciate the unique contributions made by different practitioners within the domain. The expected outputs required of the eLCCs, FeLDAs and eLearning staff under the Strategy however, may have been at odds with their roles as CoP participants and stewards.

Reflections on Community

The actualisation of a true Community of Practice may not have been realised in the eLearning implementation period. However, a community approach to adapting to the LMS migration and eLearning Strategy was certainly a defining characteristic of the process, and a catalyst for 'shift' in pedagogy, and staff development initiatives. "Sharing practice is more useful than sharing/ discussing academic position" (eLCC). While feedback on the efficacy of the Community of Practice model was mixed, there is evidence that the approach taken by Unitec had very positive outcomes in empowering staff initiatives, and providing the basis for a collaborative approach to staff development. One eLCC said:

> "My involvement in the Unitec eLearning Community of Practice was hugely beneficial to me, impacting my role both within my own department and across the institution as a whole.... Being part of a wider community exposed me to a range of other Unitec staff with an interest in eLearning. I was able to share my ideas with others from different disciplines and to adopt ideas used elsewhere to good effect. I have certainly learned a lot from the experience and continue to benefit from a number of ongoing professional relationships formed through this community." (eLCC)

Over the Strategy period, there was a visible shift in focus from Moodle tools to discussions around pedagogy. This was evidenced in eLCCs presentations at community workshops and mini symposiums for example. The scope of interest broadened to the integration of other tools with the Moodle platform as staff, delved into eportfolios, use of twitter for collaboration and introducing RSS feeds to encourage currency within the discipline in Moodle learning spaces for example. The exploration of iPads as a teaching and learning tool grew as did educational gaming and digital storytelling. There were more Web 2.0 technologies integrated with Moodle and more complex use of core Moodle tools and investigations into their application to learning. This experimentation improved the support the eLCCs could offer staff across all levels of digital literacy. The Community approach as a vehicle for staff development, and a means of facing institutional change enabled participants to own part of the vision of the eLearning Strategy, and development of eLearning use in the institution, as well as providing a forum for challenging some of the Strategy's goals. Recognition needs to be awarded to the departments who have - with the support of their eLCCs and FeLDAs - developed successful communities where sharing of best practice and continuing focus on staff development was becoming a norm.

Learning institutes considering a community of practice approach to staff development would benefit from adapting the model to meet specific institutional goals and the pedagogical changes sought. The selection process for new eLCCs requires careful consideration to achieve the best outcomes. There is the potential to exploit the early adopters' willingness to understand and apply eLearning in their teaching practice. These devoted individuals often step forward and act in this capacity for their peers regardless of time release, and as such, time release is an appropriate recognition of their contributions and addresses the workload inequalities this can raise. Existing peer-relationships allow eLCCs opportunities to model and disseminate best practice among their teaching team, in an informal and non-threatening manner, but the importance of dedicated support from management in optimising the impact afforded by these opportunities should be recognised. While the roles of the community participants require flexibility to be responsive to their community's needs, clear guidelines and shared understandings of the role between eLCC, peers and managers will reduce role ambiguity, and improve outcomes.

Where to from here?

The Faculty eLearning Development Advisor positions have been extended to maintain momentum in embedding eLearning into teaching practice. A number of Departments have self-funded time release for key staff to continue developing their peers. Additional departmental positions have been created out of a deeper understanding of the value in supporting staff to embrace eLearning. Since the conclusion of the initial eLearning Strategy implementation phase, tailored communities of practice have been emerging in response to staff interests and skills, knowledge and experiences acquired over the past two years. These communities are evidence of an institutional shift in approaches to staff development, and have empowered teaching staff to initiate their own fora for exploring interest topics. It appears that true Communities of Practice are now developing in the wake of the eLearning Strategy, and that the emergence of these communities has been facilitated by the opportunities afforded by funded time release for staff development and community participation.

Moodle and the Living Curriculum

Tabitha Roder
Te Puna Ako – eLearning academic development
Unitec Institute of Technology

Nicoletta Rata-Skudder
Faculty of Social and Health Sciences
Unitec Institute of Technology

This paper discusses how Moodle can act as a catalyst in transforming teaching practice. During Unitec's implementation of a new eLearning Development Strategy, framed within a broader teaching and learning initiative referred to as the Living Curriculum, the institute migrated from Blackboard to Moodle. Reflecting on this transition period, the authors identify how the social constructivist approach underpinning Moodle complements and can be employed to facilitate and incorporate the characteristics of Living Curricula. An overview of Unitec's characteristics of Living Curricula is given, with four themes providing a framework for their application. An investigation of the Moodle tools through the lens of these themes enables us to relook, rethink, and redesign our learning spaces. Examples illustrate some of the affordances of Moodle in enabling a Living Curriculum, and lead to a reflection on the support required to encourage teachers as learners to recognise these affordances for their pedagogical potential. Discussion around the design and intent of Moodle leads to a consideration of how teachers dispositions ultimately impact on the tool's employment.

Keywords: Moodle, Living Curriculum, tertiary, teaching practice, affordances, dispositions

Background

Unitec is New Zealand's largest Institute of Technology providing vocational and applied professional education from Certificate to Doctoral level, with four campuses in Auckland offering mostly face to face delivery courses but with an increasing demand for more flexible delivery options.

The institution purchased a Blackboard license in 1998 and for the majority of courses was a repository for core documents and a means for announcement broadcasting. In 2009 an evaluation resulted in the decision to adopt Moodle as the institutional learning management system (LMS). The migration to Moodle was launched within the context of two significant institutional strategies; the Living Curriculum and eLearning Strategy.

The Living Curriculum

In 2010 Unitec began implementation of a transformative initiative described as the Living Curriculum. Development of the Living Curriculum was closely informed by discourse around transition pedagogy and social constructivism. It is defined by a number of key characteristics including complex conversations, curiosity, focus on practice, social constructivism, blended learning experiences, research-informed, interdisciplinary, literacies for lifelong learning and embedded assessment.

Using the key characteristics, Unitec developed a set of principles of learning and teaching (conversation, curiosity/enquiry, collaboration, self-efficacy, problem solving, creativity, and reflection). In analysing these, four key themes emerge; enquiry, discipline, autonomy and conversations as shown in Table 1. Embedded in each theme is the concept of Ako - the Māori concept of teaching and learning as a reciprocal, connected and interrelated process "where the educator is also learning from the student and where educators' practices are informed by the latest research and are both deliberate and reflective. Ako recognises that the learner and whānau [familial community] cannot be separated". (Ka Hikitia 2008, p. 20)

Table 1: Ako: learning together, Unitec pocket guide to the Living Curriculum (Unitec, n.d.)

Conversations *how learners engage with self and others to develop understandings*	**Ako as puawaitanga**. Ako acknowledges that curriculum development derives from diverse forms of intercultural communication.	Conversations about enquiry, knowledge, practice, learning and teaching are significant for engagement between and among learners, teachers, practitioners, communities, scholars, and with self and texts. Conversation develops beyond chat or discussion and becomes true dialogue that involves analysis, synthesis, critical thinking and reflection. Effective conversations help to build inclusive relationships, involve questions as well as answer, and facilitate the expression of different points of view. Conversations are contextually situated, and both technology and relationships mediate and facilitate conversations.
Enquiry *how learners go about asking and answering questions*	**Ako as wānanga.** Wānanga informs the curriculum through critical enquiry. The relationship of the learner and the teacher is interdependent, and reciprocal for personal and communal good. In this context, the teacher is prepared to learn from the learner.	The process of enquiry is at the heart of the tertiary learning experience. It necessitates reflecting on the world within the perspective of a domain, formulating a question, locating information in response to the question, interpreting and testing ideas and information, generating and synthesising ideas, and presenting and reflecting on the process. Synthesis, reflection and evaluation will in turn generate questions for further exploration.
Autonomy *how learners increasingly develop their capability and confidence*	**Ako as mana**. Mana binds the authority of learner and teacher with matauranga (knowledge). Integrity is developed through a process of poutama (scaffold learning).	Individuals taking increasing charge of their own learning, which may be best achieved through a scaffolded and staged process of learning how to learn, planning, managing and reflecting on the process and products of learning.
Discipline *how learners engage with the knowledge that underpins the discipline*	**Ako as kaupapa**. Kaupapa is a process by which intellect internalises, distinguishes and creates new knowledge.	Defined as a community of practice which has a (contested and evolving) body of knowledge and theory, based on particular ways of knowing and practising, which is taught and applied and researched. A discipline has its own literacies and language. Members of the discipline (faculty, learners, practitioners, scholars, etc) identify with this community of practice and help to induct new members.

Underlying the Living Curriculum, an additional 'eLearning Development Strategy' was launched with the aim of developing the capability and capacity of Unitec academic staff in integrating learning technologies to enhance the learning experience offered to students.

How does Moodle fit with the Living Curriculum?

Are the eLearning Development Strategy and the Living Curriculum about Moodle? Not directly, but the affordances offered by Moodle have influenced the eLearning Strategy, and have enabled teachers to reconsider their practice and learning design, in light of the foundational philosophy of the Living Curriculum, which is closely allied with social-constructivism. (Pachler, Bachmair & Cook, 2010 p. 47, as cited in Keesing-Styles & Ayres, 2011). Barajas and Owen suggest that implementation of an LMS will only improve educational outcomes if "teaching (pedagogic effectiveness) and institutional sphere" are considered (2000).

Moodle development was informed by social constructionism which, as with social constructivism generally, regards learning as a social activity. It has a particular focus on the learning that can occur while learners are actively involved with the process of constructing artefacts for use by others ("Background", 2012). With this view in mind, Moodle aims to offer students control of shared content in many of its core activities, enabling and encouraging learners to construct and co-construct learning artefacts, and contribute towards the provision of learning experiences in the online sphere.

It warrants strong mention that the driver for adopting Moodle as the institutional LMS was pedagogical - "The eLearning Strategy was predicated on the need for pedagogic change and for teachers to reflect on their own teacher identity, views of knowledge, and the place technology has to play in facilitating these beliefs." (Keesing-Styles & Ayres 2011, p. 50). Siemens encourages institutes to define learning as their starting point for selecting a technology platform. "A clear definition of learning vision and desired future states, created through input from stakeholders (administrators, faculty, students, and information services) should provide the foundation for decision making, and the boundaries of platform selection" (Siemens, 2006). The social constructionist foundations of Moodle complemented the transformative practices proposed in the Living Curricula and eLearning strategies more completely than other LMS options.

It can be argued that the use of an LMS provides structure and a safe starting point for academic staff embarking on their eLearning journey. Had Unitec endeavoured to implement an eLearning Strategy utilising only Web 2.0 technologies without a supporting LMS, some pioneering teachers may have been successful in navigating the new territory of teaching with technology but others may have struggled without the structure accommodated by an LMS. Had Unitec implemented the Strategy whilst still using Blackboard, it would have been without the benefit of the Trojan horse effect that the Moodle transition enabled and which provided the impetus for people to realise that change was needed and inevitable. As recognised by the Manager of Te Puna Ako at Unitec "The shift to Moodle facilitates changes in learning and teaching through our eLearning Strategy framed within the living curricula" (Ayres, Pers. Comm. 2009).

Moodle's Affordances in Realising a Living Curriculum

Moodle used at its best aligns well with the Living Curriculum, and offers affordances which can facilitate learning experiences consistent with the underlying principles, characteristics and themes of Living Curricula. The design and future direction of the Moodle LMS development are driven by an intention to support social constructivist and social constructionist pedagogy.

> Moodle doesn't FORCE this style of behaviour, but this is what the designers believe that it is best at supporting. In future, as the technical infrastructure of Moodle stabilises, further improvements in pedagogical support will be a major direction for Moodle development. ("Philosophy", 2012)

James Gibson's perceptual theory of affordances (Withagen et al., 2012, Gibson, 1982) originates within the domain of cognitive psychology and has been foundational in discourse around technologies. Putnam (2006) for example, identifies four key "affordances of technology" - providing access to information; automating, simplifying and transforming tasks; representing knowledge and thinking; and communicating and collaborating with peers and experts.

The work of theorists such as John and Sutherland (2005) has led to viewing affordances in terms of potentiality, and has introduced the argument that user perceptions, rather than the tools' innate features, are more influential in determining the affordances of the tool. Fisher, Higgins and Loveless (2006, as cited in Roder & Hunt, 2009, p. 220) describe digital technologies as "tools which afford learners the potential to engage with activities", with the ability to change the way users approach tasks, thus altering and influencing the nature of the activity. Withagen et al. (2012) also suggest that affordances can encourage certain behaviours, making them more likely to occur.

A considerable body of literature explores the affordances of technologies in terms of education, with a view to the relevance of learning technologies to meeting societal needs and social approaches to learning. McLoughlin and Lee (2007) explore pedagogical choices available given Web 2.0 technology affordances and recognise the social constructivist principles of Pedagogy 2.0 afforded in social software tools. Roder and Hunt (2009) note "The kind of technology which has driven many of the changing needs of society are also providing some of the tools, now beginning to appear in Web 2.0 which can, perhaps, assist in providing educational programmes to satisfy them" (p. 220).

The following sections consider the affordances of Moodle framed within the four key themes of the Living Curriculum as described in Table 1.

Conversation

Moodle can act as an enabler for complex conversations through "tailored opportunities to share ideas, ask questions and express their knowledge" in "an environment which is flexible, both in time and space" ("Pedagogy", 2012). When discussing complex conversations we refer not to chat, but contextual dialogue that "involves analysis, synthesis, critical thinking and reflection" (Ako: Learning together, n.d.). Complex conversations explore different points of view, posing questions as well as answers. When complex conversations become part of the learning process, learners are scaffolded through the practice of collaboration and participation, towards taking responsibility for facilitating complex conversations independently. Complex conversations need to occur between learner and teachers, peers, practitioners, other stakeholders, texts and self.

Using Moodle, teachers share resources with their students in a range of format types, or by linking to websites, ebooks and library links to research databanks. Where courses have multiple teachers, the range of texts can be extensive as contributors bring with them their own experiences and interests. This can offer students a wider variety of texts to engage with, but also the opportunity to critically evaluate a range of texts. There are many Moodle tools that allow students to also share readings they come across in their own learning journey. Teachers can deliberately design activities that promote this sharing where students upload or link to relevant material and explain its relevance to the course. Resources can be discussed in forums or chat activities to provide opportunities for learners to have critical conversations with peers, teachers and invited participants.

The chat activity is used in Unitec's Captive Wild Animals course for students and teachers to discuss the texts and interpretation of upcoming assignment requirements. Students are also raising and discussing current industry news in their informal chats, offering opportunities to tailor the curriculum pathway to their needs.

The flexibility afforded by the asynchronous nature of forums allows participants to post anytime, relieving the instant response pressure in the classroom, giving students the opportunity to think about their contributions before sharing them. Forums also allow more time to discuss a topic than designated class time affords. Enabling students further opportunity to explore diverse interdisciplinary, complex and specialised interests provides customised and transformational learning experiences, capitalising on student engagement with high interest topics.

At higher study levels learners are expected to "engage in complex conversations demonstrating intellectual independence" and to "generate content and utilise it as the basis for critically reflective conversations within the discipline" (Mapping the Living Curriculum, 2010). At Unitec the online text assignment activity is often used to engage students in reflective dialogue, usually in response to selected texts, identified learning opportunities, industry or community-based practice. The online text assignment tool enables facilitators to provide feedback and provocative questions inline with the students' own reflections, encouraging learners to further evaluate, challenge, develop and critique their ideas. This is an iterative process which guides and scaffolds students towards developing independent arguments, and high level critical thinking skills.

Complex conversations in the Living Curriculum involve industry and community participation. Forums can be used to interview practitioners, employers, and industry partners. Unitec have many instances of projects conducted in partnership with industry in educating students 'for work, in work, through work'. When completing industry projects a method for communicating between students, teachers and industry project supervisors is integral to the project's success. Industry project supervisors enrolled in the course can participate in collaborative activities and communications throughout the project. These provide a vehicle for communities of practice to develop amongst participants, and relationships to develop between students and key industry stakeholders.

Enquiry

Enquiry considers how learners go about asking and answering questions. Using an enquiry approach involves thinking about the world, formulating a question, finding and organising information about the question, critically evaluating, interpreting and testing ideas and information, generating and synthesising ideas, presenting and reflecting on the process (Willison & O'Regan, 2006).

Learners entering the tertiary environment are expected to engage with questions typically determined by the teacher, but as they progress their studies they negotiate the question and eventually establish specialised questions, guided by the teacher. To facilitate this, the learner needs an environment where they can engage in and be part of decision making. Complex conversations encourage learners to formulate and refine their questions, and reflect throughout the enquiry process.

A student's first experience might consist of answering the set question using one of Moodle's assignment activities. The Online assignment tool means assessment can be iterative with feedback along the way, providing the space necessary for negotiating the question and shared decision making between the teacher and the student. Forums provide a venue for students to share their question and receive feedback from their peers on how they might clarify the question further before investing time in research. Their peers can share relevant resources, providing invaluable discussions in learning how to critically evaluate information. A well facilitated forum discussion assists in learning to take “primary responsibility for generating critically reflective conversations, sometimes in unpredictable contexts” (Mapping the Living Curriculum, 2010).

Following the enquiry process, after formulating a question the students are ready to find information. At early levels of study, students may be choosing from a prescribed range of resources, however in later study a learner needs to source information independently from a range of resources using advanced research procedures. Moodle courses at Unitec support students in being research informed by incorporating tailored links to library resources within an html block. Each is customised to assist students with discipline related research. In courses where students are required to source information independently, a teacher may setup a collaborative database activity for students to share information they have found relevant to the question. Comments and rating options in the database activity provide a channel for peer review of these student sourced resources, identifying the most valuable for their assessment purposes.

Learners initially experience a high degree of prescription, scaffolding and guidance from their teacher. The Moodle course structure allows teachers the flexibility “to construct a shared and active representation of the learning journey” (Pedagogy, 2006). Learners demonstrate intellectual independence at higher levels of study by taking responsibility for determining the direction of enquiry. Some Unitec students use Moodle courses as their research portfolio, indicating the processes they followed. Their courses have provided the means to share their question, gather information in one place, collect data, presenting their findings and reflect on the learning process. These are examples of how Moodle can facilitate an increasing level of independence and self-directed enquiry. There is a close synergy between the Moodle affordances and the gradual scaffolding towards independence.

Autonomy

To enable graduates to take charge of their own learning, a staged process of learning how to learn, plan, manage and reflect on the process and products of learning is necessary (Ako: Learning Together, n.d.). Use of Moodle can help teachers to scaffold learners’ capability and confidence in becoming autonomous learners.

Initially learners develop independence by engaging within a defined range of contexts in largely teacher-directed activities in which constructive feedback by the teacher is given. A quiz incorporating well designed feedback enables students to quickly check their own understanding of a topic and identify focus areas for further independent study. A quiz also provides teachers valuable feedback on their own teaching practice and how well a topic material and associated activities is meeting a group of students needs. Moodle 2.0 conditional activities further allow teachers to develop more individually responsive learning pathways for learners according to their prior experience, and identified needs.

The students’ independence can be built by starting with familiar contexts then including theoretical and unfamiliar contexts. They gain a deeper knowledge of their discipline in a range of contexts as they progress, and learn to operate with some autonomy and responsibility for achieving outcomes of the learning process. The conversations between students in the forums and blogs helps the teacher to gauge the literacy demands of the course and the students literacy levels, enabling them to choose texts, resources and activities as appropriate to scaffold learning.

Moodle forums can be tailored for specific purposes. A single simple forum creates one discussion thread, keeping a conversation focused on one topic. However a forum in which each person posts a new discussion topic is useful for encouraging all participants to share case studies based on their personal experience and background. The other students can then respond, allowing each student the opportunity to receive personalised peer feedback. This process is helpful for students in realising and developing an understanding of their own personal ontology.

As learners progress through study they have increased responsibility for determining the nature, quality and quantity of outcomes, and then explicit and structured input on the process of reflecting and evaluating their own learning. The Moodle blog tool can be used as critical self-reflection tool. “Individual blogs allow people to express things in a public but reflective way, often providing access to thinking that might not normally expressed in, say, a forum” (“Pedagogy”, 2006).

Eventually learners are expected to manage their own learning with some supervision and structured input from teachers on learning strategies. At higher levels they should engage capably in a range of specialised familiar and sometimes unpredictable learning contexts. Helping learners participate in group settings, taking personal responsibility for individual contribution can assist in developing autonomy. Using Moodle's groups and groupings options, mini projects can be managed through Moodle's wiki and forum activities, offering students a safe place to test their ideas. Students can contribute equally to wiki pages for shared assessments, and groups can be kept separate or made visible to the rest of the class.

Students need to be able to evaluate their own work and capably evaluate the outputs of others. This requires self and peer assessment guidelines and skills to be introduced and supported. The workshop module provides a method for peer assessment of students work but is often neglected as a difficult to use Moodle tool. This impression is confirmed in the Moodle Documentation ("Workshop module", 2012) which recommends giving both the teacher and the learner experience with different assignment activity types first. Students can submit work online and via attachments, and receive grades for their own work and their peer assessments of other students work.

To help learners participate in relevant communities of practice within their discipline, the notion of Community of Practice must be introduced and developed, opportunities to operate as a community with direction on roles and responsibilities needs to be given, and guidance provided on cooperatively managing the dynamics of the group.

Discipline

This theme addresses how learners engage with the knowledge that underpins the discipline or domain. A discipline is defined as a "community of practice which has a (contested and evolving) body of knowledge and theory, based on particular ways of knowing and practising, which is taught and applied and researched" (Ako: Learning together, n.d.). Members of the discipline may include teachers, learners, practitioners, and researchers, all of whom help to induct new members into the culture, identity, language and literacies of the domain.

In early tertiary experiences, teachers guide students to engage with knowledge from selected sources with the aim to reach shared understandings. Collaborative glossaries using comments and ratings are a simple but effective means to develop literacies and shared understanding within the discipline. Because the Moodle glossary tool allows for duplicate entries, the teacher can ask all students to define the same term using their own words, and then discuss why their definitions differ. The combination of differing literacy levels, backgrounds and experiences, and context can give rise to engaging conversations among learners about their interpretations. From this process emerges a deepening understanding for all students and the opportunity for students to evaluate and acquire an understanding of theoretical concepts situated within familiar and personalised contexts. These processes are formative to a learner's identity within the discipline because as students develop a 'command' of knowledge in specialised areas they begin to engage in knowledge creation. The learner has to understand the relationship of specific knowledge to the discipline so they can independently and creatively apply conceptual knowledge in complex, variable, specialised contexts (Mapping the Living Curriculum, 2010).

Guided conversations with peers and teachers about analysing and interpreting problems and identifying appropriate responses, lead to learners synthesising disciplinary knowledge and linking relevant disciplines to their practice. The Unitec Department of Performing and Screen Arts have a shared Moodle course which showcases each of the different disciplines within the Department, exposing all students to the news, ideas and culture of related but separate domains, and encouraging cross-hybrid innovations to occur.

Students beginning to construct and reflect on their disciplinary identity in their initial studies subsequently progress to having interdisciplinary conversations about multiple perspectives from a disciplinary base and interdisciplinary collaboration. Learners will construct and reconstruct a disciplinary identity based on their engagement with disciplinary and interdisciplinary knowledge.

To integrate discipline-relevant examples the remote RSS feeds block can be implemented. Unitec's Nursing in Community course incorporates a feed from the Health section of the national newspaper. The course also incorporates international case studies relevant to each topic. Discussions about industry case studies and current news expose students to the variety of options their study can lead to in terms of a career path.

Teachers can collaborate in Moodle courses with industry partners providing external mentors and expertise, and educating students through real-world work contexts. The Unitec Department of Education has initiated a Moodle course to facilitate an Early Childhood Education Network, inviting employers to become part of a community, sharing best practice, discussing industry legislative changes, and providing stronger connections aimed at improved outcomes for students in work experience or practicum.

The value of real world workplace assessment is not missed in Moodle; the offline assignment activity gives teachers a method of advising students on their assessment requirements and recording their grades in the central hub that the Moodle course so often becomes. Another method to facilitate assessments based on authentic scenarios is to use advanced uploading of assignments. This assessment type allows students to submit a portfolio of all the files associated with the assessment. An example might be a project to build a boat, where the student submits a time-lapse video of the building process, along with the blueprints of their design with any amendments made during the process, a spreadsheet of their costings, and a reflective summary of what they learned and how they would like to approach the next project. The student can thus demonstrate their ability to generate and analyse data, come to coherent conclusions about their topic of investigation, and present their findings in discipline-specific formats. Giving employers and industry partners access to the course and encouraging their participation assists teachers in ensuring teaching, learning and assessment are appropriate to the discipline.

Considering Teacher Dispositions

Unitec leadership recognised that in order to fully integrate eLearning into the Living Curricula, institutional capability had to be developed and support structures provided to enable an optimal response to the new demands being posed (Roder & Rata-Skudder, 2012). Whilst some academic staff embraced the opportunity to experiment and innovate independently, many highly capable teachers in the face to face environment were challenged by these changes.

Recognition of Moodle’s affordances may be dependent on the dispositions of the teacher (John and Sutherland, 2005). Despite the design and intent of a tool, it is not necessarily the technology which inherently drives its educational application but the culture, context, and the dispositions of the users which will impact how the tool is employed. Existing Unitec research validates this hypothesis, “the radical pedagogical changes … were not because of the technology itself, but rather how it was used” (Narayan, 2011, p. 899).

Thornton (2006) defines dispositions as “habits of mind ... that filter one's knowledge, skills, and beliefs and impact the action one takes in a classroom...” (p. 62). As observed by Carr et al. (2010) “learning includes knowing why, knowing when and where, and knowing how, to use knowledge and ability” (p. 16). An individual’s circumstance and experience impact their disposition, and therefore the ways in which they approach new and unfamiliar learning contexts. Dispositions therefore “are the source of the recognition (or misrecognition) of learning opportunities and provide strategy and motivation for the inevitable improvisation that is learning” (Carr et al., 2010, p. 15).

It is well known that lack of training and support impacts negatively on teacher competence, confidence and motivation in integrating the use of ICTs (Guskey, 2002, Overbaugh & Lu, 2008). Conversely, teachers who can confidently use technologies in their practice are likely to understand the benefits and pedagogical potential of ICT integration (Bingimlas, 2009). The Ministry of Education (2007, cited in Carr et al., 2010, p. 16) suggests that as learners successfully develop competencies they become more inclined to apply them and recognise the opportunities and reasons for doing so.

However, the dispositions of a teaching practitioner may not be immediately transferable when confronted with a vastly different teaching context. Resnick (1987) found that when people are encouraged to implement a particular learning strategy, they may do so successfully in the short-term or familiar contexts, but will subsequently fail to apply the same strategy to other opportunities. Zhao et al. (2002) concluded that teachers who engaged with new innovations that significantly differ from their usual practices, and the cultural norms of their teaching environments are generally ill-equipped for success. Therefore, where teachers struggle to apply existing teaching dispositions and strategies to new situations, the need for carefully constructed support is paramount. Claxton and Carr (2004) suggest “the environment may need to invite learners to participate, actively engage them and include their prior knowledge in conversations and interactions of joint attention, or provoke them to recognise opportunities that are unfamiliar and new” (cited in Carr et al., 2010, p. 18).

In studying the conditions necessary for technology innovation in classrooms to take place, Zhao et al. (2002) found three significant factors for success: technology proficiency, pedagogical compatibility, and social awareness. They found that "teachers need to know the affordances and constraints of various technologies and how specific technologies might support their own teaching practices and curricular goals" (p. 489). Their studies showed that teachers needed support from people beyond their usual sphere of interaction. Additionally, Tishman, Jay and Perkins (1993) suggest thinking dispositions are learned through a process of enculturation, and use four elements in teaching thinking dispositions: modelling, explanations, peer interactions and both formal and informal feedback. Interviews with Unitec Academic staff have revealed this approach can work in the context of this learning institute. "At the eLearning mini symposiums you see how Moodle can be utilised and hear staff talking about successes they've had, so I see scope for being innovative and creative in teaching" (Unitec academic staff member, 2012).

Summary

Moodle offers a wide range of ways in which people can create representations of their knowledge and share them, and these affordances align closely with the characteristics of Living Curricula. On the one hand, the affordances of Moodle can help encourage specific design-intended behaviours in teachers and learners, and the Unitec experience illustrates the usefulness of Moodle as a Trojan horse for covertly challenging existing technology mediated teaching practices, and introducing those practices in a way that is better aligned with the principles of social-constructivism, and Living Curricula. However the perception of the teacher influences how or whether the affordances of Moodle tools are recognised. Explicit modelling of optimal tool use is likely to encourage users to adopt those behaviours afforded by the technology. In preparing teaching staff to recognise the pedagogical affordances, further intentional strategies need to be employed to address the teachers' perceptions if they are to successfully transfer their teaching dispositions to the new context of learning technologies.

Current discourse suggests that in equipping teachers to identify the pedagogical affordances Moodle has to offer, teachers as learners need to be actively engaged in conversations which connect their prior knowledge and perceptions to new contexts, support their understandings and the pedagogical implications of the technology, and the place of technology in their social context and broader learning culture. Formal and informal interactions with other practitioners, both within and beyond the teacher's usual sphere, are important in preparing teachers to understand the usefulness of various technologies in reflecting, extending and transforming existing pedagogical approaches. Additionally, importance is placed on the provision of best practice examples, feedback, explanations and modelling of the pedagogical affordances of technologies for learning.

The dispositions required in recognising the affordances of Moodle and integrated learning technologies can be learned and transferred, but the processes which encourage application of enabling dispositions need to be iterated in order to encourage ongoing success for teachers implementing technologies in their teaching practice. Through challenging a stance, teachers will gradually change behaviours and acquire the necessary skills, modifying their dispositions as a result. Dispositions can change over time, with the right teaching and technical support, and through facilitating opportunities for teachers to experiment, evaluate and learn from their collective experiences.

Naming and measuring the elephants: sustainable change for blended learning

Carol Russell
Teaching Development Unit
University of Western Sydney

Educational development work to replace traditional campus university teaching with more innovative blended learning activities usually involves articulating and questioning assumptions about disciplinary learning. But the assumptions built into the discipline and institutional organizational systems for managing study times and staff workload planning can block innovation. Several previous projects have established that intensive team workshops over 2-3 days, involving support staff working with academics to produce real outputs, can build sustainable capacity for curriculum innovation within academic units. This paper describes current work in one university that makes use of disciplinary curriculum mapping and explicit planning of academic and student workload in the educational design activity. Two pilots in different disciplines are being used to develop a model that can be applied and contextualized as part of a broader sustainable blended learning strategy.

Keywords: blended learning; teaching workload; student workload.

Background and context

The context is an Australian multi-campus University that recognizes the need to use newer learning technologies to provide students with a more flexible and engaging learning experience. The School of Business is embarking on a major program of curriculum redesign, to address concerns about competition in the market for Business degrees – especially from providers offering more flexible study options. The School of Nursing & Midwifery is introducing two new undergraduate programs in 2013, and has decided to replace all lectures with alternative online activities. Both Schools are being given additional resources to support these initiatives, as part of the institutional blended learning strategy.

Like many campus universities, there are few established processes for substantially innovative blended and online learning design. There is central e-learning and teaching staff development support. But until now the primary mechanism for introducing new methods and technologies has relied on individual teachers as 'early adopters' (Rogers, 2003). As a result, individual teachers can often only make incremental changes within established programs.

Salmon (2005) argues that simply adding e-learning incrementally into existing practices in campus universities will neither improve quality (in terms of flexibility and efficacy for student learning) nor improve efficiency (in terms of costs). She likens the incremental approach to early attempts at human flight based on flapping wings, when a completely new principle was needed to achieve powered flight. Academic communities tend to be conservative in their approaches to teaching and learning, and individual innovators usually encounter resistance when they try to make significant changes to teaching practice. There are good reasons for this. Disciplinary teaching is a complex system relying on distributed expertise and tacit knowledge, at multiple levels of the university (Russell, 2009). Most of this tacit knowledge is about traditional classroom teaching methods. So for blended learning to fly, we need a systemic team-based approach that gives time and space for rethinking pedagogy, with collaboration between discipline academics and with specialist support.

However, staff workload assumptions, and measuring teaching effort is an 'elephant in the room'. Academic departments, and individual academics, are often reluctant to be too specific about how they spend their time. Formulae used in enterprise bargaining agreements include assumptions that may not adequately account for new types of teaching work. Student learning time can be another 'elephant' in that teachers will often struggle to quantify the time that students take to carry out learning tasks, especially in classes with diverse backgrounds and levels of study skill. Sustainable introduction of blended learning requires that these elephants are not only named, but measured up and allowed space, to avoid completely crushing the benefits of blended learning (Laurillard, 2007).

Building on previous work

Figure 1 summarises some of the previous work on blended learning design that can be built upon. The Curriculum Renewal and E-learning Workload: Embedding in Disciplines (CREWED) model piloted at UNSW (Russell, 2008) and the Course Design Initiative (CDI) at Oxford Brookes (Dempster et al., 2012) were both designed to challenge curriculum assumptions through an intensive 2-3-day team-based design and develop hands-on workshop. Both draw on Salmon's *Carpe Diem* model, which is set up to generate tangible products, in the form of an overall plan and reviewed samples of online learning activities in two days. Another model developed at the University of Hertfordshire – Change Academic for Blended Learning Enhancement (CABLE) has an organisational change focus (Anderson et al, 2008). It was preceded by institutional benchmarking on eLearning capacity, includes a two-day residential and aims to establish ongoing relationships with staff in the central Blended Learning Unit. Central to all versions is a shared planning and visualisation exercise, where the overall learning design is developed collaboratively by a team of discipline academics and educational support staff.

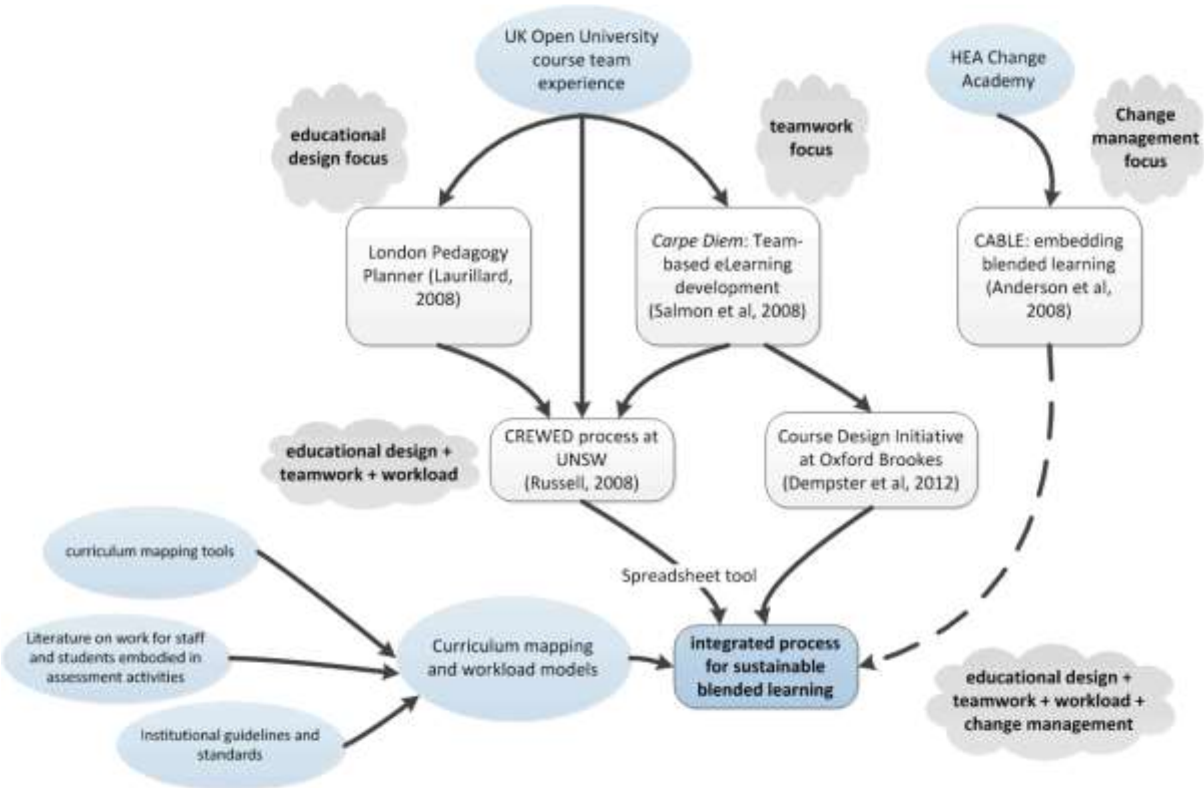

Figure 1. Learning from previous work on curriculum design for blended learning

All of these differ substantially from the more common practice of educational designers and developers working individually with academics through a series of one-on-one consultations. Instead, there is a structured and facilitated process in which a whole team, or in the CDI case sometimes multiple teams, develops a shared visualisation of the learning design. As in the original Open University (OU) course team model, peer review and testing of activities are built in rather than added afterwards. However, the intensive two-day workshop replaces the OU's extended team process, which was developed for large-scale distance education – hence Salmon's choice of the name *Carpe Diem*.

Workload planning in pedagogical design

If e-learning activities in blended learning are treated as an add-on to existing practice, the time required from students and from teachers can blow out to unmanageable proportions. Often there is little hands-on support and teachers have to learn to use the technological tools themselves. A study by Tynan et al. (2012) in four Australian universities found that academic work on online or blended learning 'requires more thorough auditing within specific contexts. Student workloads also need to be managed effectively. Laurillard's Pedagogy Planning (Laurillard, 2008) tool sought to make the types of student work involved in different types of learning design more explicit.

Mapping learning outcomes and assessment

In the original version of the *Carpe Diem* process, Salmon required that all participants had completed her e-Moderating online course. However, this has not always proved feasible (Russell, 2008; Salmon et al., 2009) The 2-day workshop starts by clarifying learning outcomes and reviewing examples of online learning activities before starting on the educational design. In some of the UNSW cases, the first part of the workshop took longer and was more problematic than time allocated had allowed for. When the academic team are both unfamiliar with online interaction with students, and have poorly defined learning outcomes (e.g. focusing on content rather than on what students can do), it is hard for the team to move beyond traditional practices. This is because many of the assumptions about classroom teaching and learning interaction remain tacit, and teachers lack experience of online facilitation. Prior work with the academic teams to articulate and map current practice helps to address this problem.

Current pilot implementation

The current pilot involved running two instances of an intensive design and build workshop process, one for the Property major in the undergraduate Business degree, and one for core units (subjects) in the undergraduate Nursing and Midwifery degrees. The Property program offers distance and campus based study options, and is keen to improve the distance student experience. Three units are being redesigned for semester 2 of 2012, and evaluations of these will be available by November. The Nursing and Midwifery work is for semester 1 of 2013, and is a more radical redesign, in that six core units will be designed to replace all lectures with online activities, while maintaining small group face-to-face tutorials and practical classes. Both disciplines have their own educational models, which can provide starting points for the design process. In both cases there are also external accreditation frameworks that shape the learning outcomes and their assessment.

There are a number of institutional resources available to support the change. We have a comprehensive set of data on the student perspective on use of IT from a survey in 2010, and from routine student feedback systems. Analysis of responses from 1st year Business students has already proved useful in challenging some teacher assumptions about what is feasible. We also have:

- A spreadsheet tool developed by the School of Business for estimating the work embedded in different types of assessment activity, for students and staff, based on published research
- Institutional e-learning quality standards, recently updated
- Curriculum mapping tools to enable each study unit or subject to be designed in a program context (two versions, based on models developed in other universities)
- A spreadsheet tool to capture educational design of each unit, including learning activities, assessment, student workload, staff workload.

The School of Business has been using their 'embedded work' tool for all assessment activities across the undergraduate degree. The School is also using curriculum mapping tools to put assessment activities within units into the context of program learning outcomes. Similarly, the School of Nursing program has had to map its curriculum and assessment for accreditation purposes. Already, some workload planning problems have surfaced, which will need to be addressed to accommodate the shift to blended learning. One is that teaching staff time is allocated only for the semester in which teaching occurs, making it hard to get teachers to commit time to the required design and development in advance.

By including explicit consideration and negotiation of student and staff workloads, we aim to address simultaneously educational design, team-building, workloads (for staff and students) and change management. Each academic unit has established processes for assigning work to academic staff, and there is an over-arching agreement at institutional level on how workloads are allocated. Some of the guidelines and processes will need to be reviewed and adjusted, or at least re-interpreted, to implement blended learning effectively.

Figure 2 summarizes the process being piloted. As with the Oxford Brookes CDI project, it will be necessary to adapt the scale of each two-day workshop to the context. Two pilot workshops were held in July 2012: one for three subjects in the School of Business Undergraduate Property Program and one for six 1st year undergraduate subjects in the School of Nursing & Midwifery.

Both Schools involved in the pilots are planning to roll out further development of blended learning across their undergraduate curricula in 2013 and 2014. Each pilot will therefore inform a School-based version of the process. In both cases there is parallel work going on to map the curriculum in relation to accreditation requirements for the degree programs. Curriculum mapping is an important preliminary step, because it clarifies

Unit learning outcomes. Agreed and well formulated learning outcomes are a prerequisite for articulating and questioning tacit assumptions about learning and teaching practices in the discipline. Once these two Schools have successfully run the process several times, it should be possible to develop a standard process that can be run and adapted as necessary for other programs.

Planning and monitoring of teaching workloads and skill development will be an important part of the pilots. One specific aim will be to identify efficiency gains that will justify investment of time spent in advance work on blended learning design and development. Another will be to identify where planning, workload models and support staff activities need to change to sustain the expansion of blended learning throughout the curriculum.

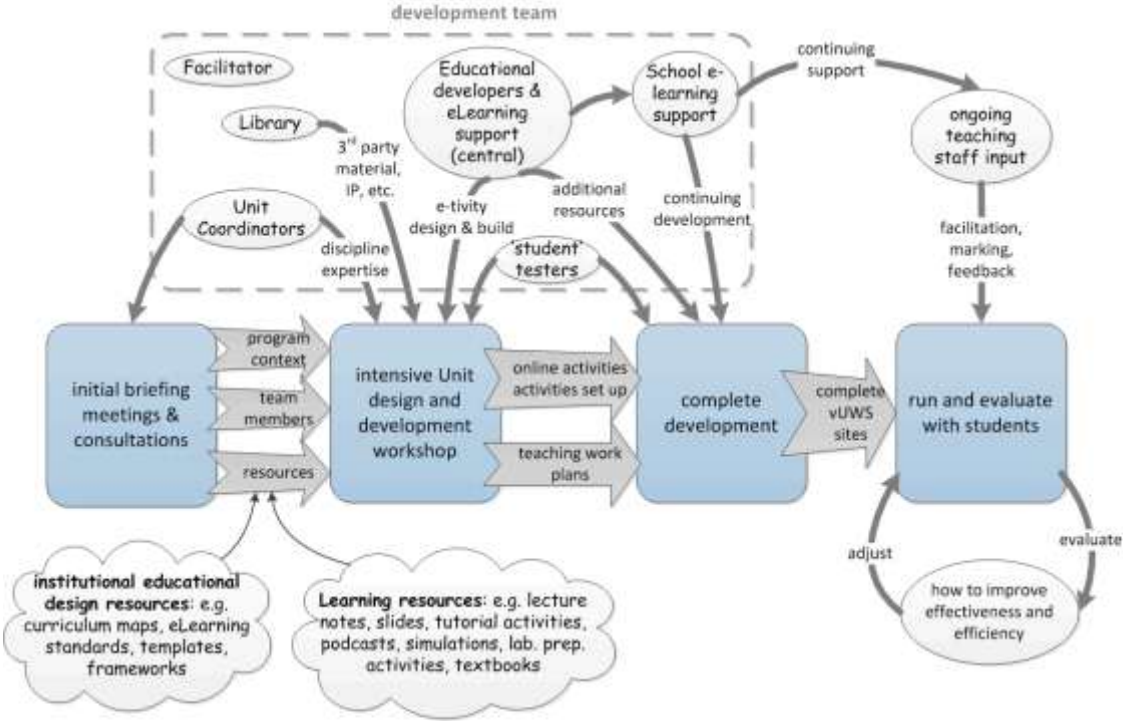

Figure 2. Blended learning design process being piloted in 2012

What we have learnt thus far

The workshop for the Property program took place over three days. The first day involved a program overview session with the whole academic team (6 academics), at which we reviewed the current educational designs and identified three basic types – each with a different assessment pattern. Then we had a two-day intensive hands on workshop with 3 academics to develop new online assessment activities for the three units running in semester 2. While there have a been a few minor glitches, overall the process succeeded in addressing the aims of the *Carpe Diem* process (Salmon et al., 2008), in that the team now has a shared approach that can be applied to other Units for next year. From the School perspective the exercise was extremely successful in that it improved the efficiency and effectiveness of assessment and feedback (for example by introducing group assessment tasks, use of formative quizzes, rubrics for marking). The fact that the School has a clear model for 'embedded work' provided a focus and a driver for the design of new online activities, as did the urgency of preparation for the upcoming semester.

The Nursing and Midwifery workshop was more ambitious – more like the multi-team workshops described by Dempster et al. (2012). We ran it for 6 separate Unit teams over two days. Attendance was patchy, with some staff unable to be there for the full two days – damaging the teambuilding process. Despite much prior discussion about the new curriculum for 2013, there may have been insufficient allowance for up-front planning and design work in the semester before the main teaching work. We were unable to fully 'seize the day' and have had to run a number of separate follow-up sessions (with each Unit team) to complete the work.

These outcomes have confirmed that team-building (Salmon et al., 2008) and workload planning for staff (Tynan et al., 2012) and for students (Laurillard, 2008) are all essential parts of the blended learning design process. We have begun to show how these complementary factors can be managed together as part of the organizational change required for effective introduction of blended learning (Russell, 2009).

RMIT University's media annotation tool (*MAT*) is a computer software program dedicated to incorporating video footage to the student learning experience in a novel manner. In addition to the usual functions associated with videos, *MAT* allows users to enter written comments at strategic and key positions to emphasise the required learning points. Innovatively introduced to creatively support learning for work-ready skills, in 2011 *MAT* was integrated into courses across nine student cohorts, over six disciplines, in the Vocational and Higher Education (undergraduate and post graduate) sectors of the university. This paper will focus on analysis of insights of teacher experiences using *MAT*, highlighting sustainable ways forward with university designed innovations. It will introduce the context of implementing *MAT* and discuss the process of evaluating the requirements for promoting *MAT* to the wider university community and, more specifically, to embed and sustain *MAT* into the long-term.

Keywords: media annotation tool, implementation, integration, embed, sustain, e-learning.

Introduction

The theory and practice of e-learning is evolving rapidly in tertiary education (for example, Haythornthwaite & Andrews, 2011; Herrington, *et al*., 2010). Teachers as early adopters have a significant role as future makers of educational technology; their experiences informing sustainable innovation. Innovations in educational technology have benefitted from project funding over the last 50 years (Gunn, 2011). Many outcomes of earlier projects will have progressively exhausted their natural life span, while others will have underpinned subsequent projects and contributed directly (e.g., through tool adaptation) or indirectly (e.g., through dissemination of findings) to currently used technology. This paper focuses on a recent in-house innovation at RMIT University in Melbourne of a media annotation tool known as *MAT*. *MAT* is an interactive and innovative tool that enables learners to engage with video. As well as basic learner-control functions (play, pause, re-play, etc.), students can anchor text entries to segments of video. Their peers (within small or large groups), and also their teachers, can add to these annotations to create structured, threaded discussions converging on key points of the footage. The video under learning analysis can be student-generated and uploaded to *MAT*, or teacher selected and uploaded such as in-house productions or third-party videos with correct permissions.

This tool was developed to facilitate deep learning through the annotation to video footage by students. The innovation has undergone various iterations and applications, most notably the recent use of *MAT* in a number of diverse programs from medical radiations to law. It is currently at a post-project funding stage. The challenge for *MAT* now is whether its use is sustainable in a wide range of programs or if difficulties with adoption by academics and students mean it may disappear over time. This paper addresses ways *MAT* can be used sustainably in the future, potentially scaling up to an embedded tool in the suite of university technology, with numerous learning cohorts benefiting across the institute.

Educational sustainability

According to the online JISC 'Sustaining and embedding innovations – A good practice guide':

> Sustainability in innovation projects can be defined as embedding change as well as maintaining and enhancing project outcomes [and] In other words, project teams might well introduce new ideas for teaching and learning but the true "innovation" is about how these ideas go beyond the pilot/test phase and are applied and adopted appropriately throughout an institution. One could therefore argue, that sustainability and embedding are an essential element of any innovation! (Chatterton, 2010).

Gunn (2010) argued that an e-learning initiative is sustainable when three conditions are met. These are related to: (i) course integration and evaluation; (ii) integration and adaption into other learning scenarios and (iii) embedding into university systems and promoting to teachers. In the time since completion of design and development of the first planned stage of *MAT*, 'Stage I' video annotation (Colasante & Fenn, 2009), integration and evaluation of the tool has essentially met the first two Gunn (2010) conditions, and is yet to embark on the third. Table 1 aligns these three conditions to the progress of *MAT*.

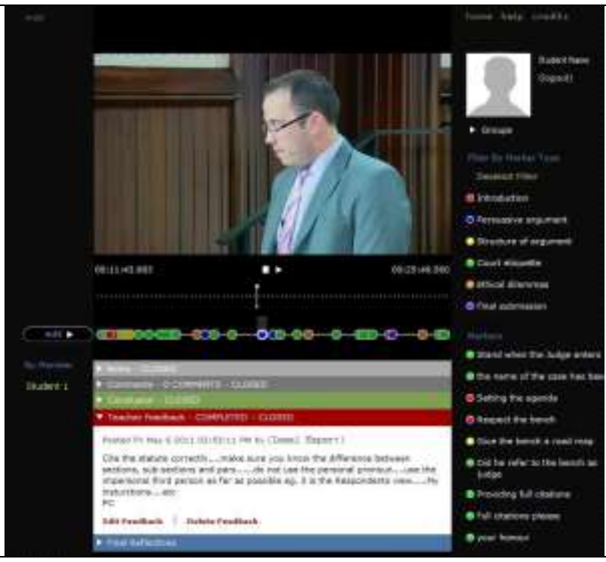
Table 1: The *MAT* initiative aligned to the Gunn (2010) three conditions of sustainability

Three conditions of e-learning initiative sustainability (Gunn, 2010, p.90)	Alignment to *MAT* progress
1. Course integration and evaluation: "A learning design involving information and communications technology has been developed and implemented within a course or courses of study. It has been through a proof-of-concept stage and has been judged, on the basis of evidence produced, to be beneficial to teaching and learning."	***Achieved.*** A pilot study in 2009 saw *MAT* integration in a physical education (PE) undergraduate course; findings were largely positive for active learner-centred engagement with video for pedagogically sound purpose (Colasante, 2011a; Colasante, 2011b). Recommendations from the pilot study included integrating and examining *MAT* in other courses, including work-preparation learning options (Colasante, 2010).
2. Integration and adaption into other learning scenarios: "The e-learning concept, design, system or resources have proven potential to be adopted, and possibly adapted, for use beyond the original development environment."	***Achieved.*** A 2011 university funded project saw *MAT* integrated across a range of disciplines and tertiary sectors of the institute. In execution, the multiple-case study approach also created an effective community of practice for sharing of ideas. Evaluation is progressing, and early data analysis indicates that the tool is more effective in engaging learners where learner-learner and learner-teacher interactions are designed into the learning, where there is clear alignment with assessment, and where video upload to *MAT* is managed by teaching or support staff rather than the students (Colasante & Lang, 2012).
3. Embedding into university systems; promoting to teachers: "Maintenance, use and further development of the e-learning concept, design, system or resources do not remain dependent on one or a few individuals who created them, to the extent that, if their involvement ceased, future prospects would not be compromised."	***Yet to be fully embarked upon.*** Maintenance of *MAT* continues (albeit relies heavily on the initial web developer) and improvements have been implemented as a result of teacher and student feedback across the multiple-case study. The innovation is still only known by a relatively few teachers across the university, although sharing through seminars (recent and planned) should improve this. In the university's educational technology landscape, *MAT* has not yet moved from 'student-facing pilot' to 'ongoing'.

The third condition—that of embedding into university systems and promoting to teachers—is a preferred way forward for *MAT*. Use beyond the university is also not unimaginable, as proven possible, for example, by the internationally deployed *VideoANT* (Hosack, 2010). The post-project stage will likely fall to others, instead of the funded project team. While the project team (primarily teachers and learning support academics/ professionals) were effective in further proving the concept and developing a community of practice, the skills required "to extend use of the product and findings beyond the development environment; that is, to address a key sustainability factor … are not the same as those for promotion or dissemination.", and so "the Principal Investigator or research team are not usually responsible for these later activities" (Gunn, 2010, p.98). Project team members are, however, keen to play a minor and/or hand-over role, to complete the project cycle towards the future success of integrating *MAT* into learning and teaching. This may include providing teacher ‘champions’ in promotional activities, and learning support professionals in teacher professional development and learning design roles, as well as sharing findings. The next section of this paper gives detail of the 2011 project that provided for the integration of *MAT* in various disciplines.

The tool and the funded project

MAT is a web-based annotation tool that currently allows textual annotations to discrete segments of video, which may be further added to by others in threaded discussion panels. The *MAT* project was funded by a 2011 university grant and titled ‘Using a media annotation tool to enhance learning that is work-relevant and enables industry collaboration (A multiple case study evaluation across disciplines and sectors to inform models to achieve this)’. It was aligned to the university strategic objective: ‘To be work-relevant and industry-partnered’, and followed a successful 2009 pilot evaluation of *MAT* integration in undergraduate physical education (PE). The 2011 project incorporated a collaborative approach by academics from varied disciplines and across academic colleges, as well as learning support professionals. Each academic had his or her own specific work-relevant learning needs for integrating *MAT* into learning and teaching, and most included industry representative participation in the learning processes (see example in Figure 1). The participating teachers, from the disciplines of medical radiations, chiropractic, and education (undergraduate); law (postgraduate); property services, and audiovisual technology (vocational); formed key project contributors, plus their student cohorts.



Industry representative participation

Industry professionals participated primarily by involvement in video production (by interview, or demonstrating or role playing practice) and/or providing feedback to students in *MAT*.
In the use of *MAT* for the Juris Doctor (JD) cohort, illustrated here, two legal industry representatives participated by co-scripting ‘moot court’ proceedings with the JD teachers, and then acting as judge and barrister in the video that the students subsequently analysed.
Further, one of the legal representatives provided direct feedback to the student groups on their moot court video analysis work in *MAT* (an example of which can be seen in the red ‘Teacher Feedback’ text panel).

Figure 1: Screen capture (de-identified): Example of the use of *MAT*, with markers and anchored text.

Examination of the project was via a multiple-case study of the varied learning cohorts’ use of *MAT* in their respective work-relevant contexts, to inform models of *MAT* use and to develop guidelines and publications to support wider application of such models. The project produced both process and product outcomes (Colasante, *et al.*, 2012). For example, the process of integrating this new educational technology into nine case cohorts over six disciplines involved *MAT* training and support mechanisms for teachers and students, learning design, and meetings and reflections on the various case applications of *MAT* in a project-wide community of practice. To inform the models (currently in development) of work-relevant learning that optimise virtual authentic learner engagement by integrating *MAT*, a range of data was collected. Surveys, observations, interviews and learning artefacts captured the student experience over two semesters (being reported in other papers). The teacher experience (plus that of industry representatives where possible) was harnessed by ‘interactive process interviews’ and cross-validated by post-subject artefact analysis of learning evidence within *MAT*. These interviews were semi-structured, lasted 30-45 minutes and were audio-recorded. The first 10-15 minutes involved the teacher demonstrating the processes of *MAT* use in their cohort, by a think-aloud walk-through of examples within the tool, followed by interactive questions using a themed protocol. In a minority of cases, the first part of the interview involved observation of active feedback processes in *MAT*. For the focus of this paper, emergent themes from the teacher interviews are discussed and analysed in regards to *MAT* sustainability.

Multiple Cases of *MAT* Curriculum Integration

Below is a summary of the various cohorts using *MAT* including the ways *MAT* was using video content and industry involvement, as well as the number of students (Table 2).

Table 2: The nine *MAT* course integrations

Tertiary sector		Discipline	Work-preparation theme	Video content	Industry involvement	Number of: students in MAT;	teachers in project
Post-graduate	'JD'	Juris Doctor (law)	Advocacy skills	Scripted and acted moot court proceedings[1]	Video co-scripters and informed actors; feedback to students in *MAT*; guest lecture	32	3
Undergraduate	'Education'	Education (literacy)	Literacy teaching skills	Students storybooks in development[2]	Guest lecture from an author of children's books	18	1
		Education (visual arts)	Visual arts teaching skills	Students own art processes and art environments[2]	Practical placement in schools including art classes	59	1
	'Health'	Chiropractic	Clinical thinking for clinical cases	Scripted and acted chiropractic consultation in two parts[1]	Video scenarios co-scripter and informed chiropractic actor	78	2
		Medical Radiation	Image evaluation skills	Senior radiographer critiquing a range of x-ray images[1]	Expert radiographer in videos	57	1
Vocational Education and Training (TAFE)	'VET'	Property Services (Cert IV, traineeship)	Customer service	Teacher interview of 3 professionals across different sized companies[1]	Experts in property services industry in videos	20	1*
		Property Services (Cert IV, owners' corp)	Conducting meetings	Student role-plays of industry-styled meetings[2]	Concurrent employment in the field	29	1*
		Property Services (Diploma)	Customer service and leadership	Teacher interview of a professional from a large company[1]	An expert in property services industry in video	22	1*
		Audiovisual Technology (Diploma)	Quality service	Two commercial videos on customer experiences[3]	N/a	39	1
TOTAL		**9 cohorts (6 disciplines)**	***Notes:*** *[1]Professionally produced videos (in-house or contracted)* *[2]Student-generated videos* *[3]Third party videos*	**Same teacher (across 3 courses)*		**354**	**10**

A major part of the 'process' outcomes of the project involved integration of *MAT* into the curriculum of varied learning cohorts. By integrating this new educational technology into nine case cohorts over six disciplines and across university sectors (see Table 2), direct outcomes included:

- 354 students having access to *MAT* in their learning
- 10 teachers exploring how to achieve various work-readiness learning objectives via an interactive multi-media approach using *MAT*
- project-wide community of practice, with sharing of teaching and learning experiences with *MAT*
- sub-communities of practice: a research group (over 50% of the project team), and a small strategic group (one member from each of the three academic colleges)
- five small group technical training sessions for participating teachers (plus five teaching assistants employed under project funding), over two campuses

- 13 in-class technical training and learning with *MAT* support sessions across the nine student cohorts (including repeat tutorial-sized sessions for the larger classes).

Teacher perspectives on the use of *MAT*

A number of issues emerged from the teacher interview data that raise issues of sustainability. These can be categorised under the themes of: recommending *MAT* to other teachers; technology ease of use; support mechanisms; future use; and professional development.

Recommending *MAT* to other teachers

All ten teachers recommended *MAT* for other teachers to use. Some added qualifiers, such as recommending a pedagogical fit for purpose, not using *MAT* in isolation of other learning strategies, and the need for support, time and cost coverage in relation to video production. For example, participants stated:

> Yes I would [recommend it], but I think it needs to be thought about exactly how it should be integrated into … their learning, their teaching … I don't think it's something that you could just use *MAT* and nothing else, I think it should be integrated as part of your package for your delivery for that particular program. ('VET' teacher-1)

> Yeah, I think it's a great innovation; I think it's a great visual tool; it's a very reflective tool; it's very active learning because you're engaging in dialogue; I love the industry element that we included, the industry representative. … [and advise other teachers] just to give themselves time to prepare; to use the instrument themselves if they can– and also I think to recognise that cost is a big part of any learning and teaching innovation and this is a pretty big innovation. It's been excellent but it's a big leap. ('JD' teacher-1)

Technology ease of use

The ease of using the *MAT* technology was not an explicit question in the teacher interviews, however, six out of ten teachers volunteered in interview that *MAT* was easy to use, and one of these teachers noted a pre-conceived view that the tool would prove difficult to use, and was relieved that it was not. Two teachers offered that the technology was quick to learn, for example,

> it's very easy to navigate through, because as I said, it only took me half an hour to figure out how most of the things work … [and] it was very easy to use, it can be flexible, everything is all there stored, I was able to log onto it ... when I was working from home. ('Health' teacher-3)

Seven teachers noted that time was a factor in their adoption of the tool, in that either *MAT* activities took up a lot of their time, or that they worried about the time commitment once the project supports were removed (e.g., project funded teaching assistant). For example,

> working with *MAT* in the future, we all know how to do it, to enrol the members, to put media in there … [etc.]. But because you have to do one group at a time, that admin aspect is actually fairly labour intensive and we had the luxury of the Teaching Assistant … it's one of those activities that you would have to realise are admin rich … with larger groups. ('Health' teacher-1)

Another factor relating to technology involved student ability. While some student cohorts coped with the technology easily, such as the Audiovisual Technology and Juris Doctor cohorts; other students had some difficulties. For example, the Property Services teacher appreciated in-class technical support for his mature-aged students, as some very basic technology ability gaps were evident and these needs required direct technical support. The Education-Visual Arts teacher felt her students were not the "tech-savvy" digital natives that she expected them to be, and noticed they needed more technological support than anticipated. Uploading student-generated video was a particular frustration for this cohort. In addition to the research interviews, the Education-Visual Arts teacher shared her student experiences in the project-wide community of practice, which helped other teachers prepare and/or arrange additional support to enable a smoother process, for example,

> at this stage, *MAT* needs to download the video overnight – and I really like it as a tool that students can use for videos that have already been downloaded by either for them or by the teacher because I think it's important that they don't get bogged down in the back end of *MAT* …

> If I had of expected my students to download their own videos … [as well as] put in their own markers I wouldn't have had the high participation … that I achieved. ('VET' teacher-2)

Support mechanisms

Technological and video production costs were factors widely raised by teachers. Another concern was the withdrawal of project supports affecting the ongoing use of *MAT*. For instance, one of the Property Services cohorts (Cert. IV, Owners' Corporation) required significant support. This cohort required filming of four student groups' simultaneously conducting role-plays of meetings, in evening classes, using 'Flip' cameras purchased with project funds. The cameras remain available after project funds are exhausted, but funding for additional staffing support is not ongoing. A snap shot of teacher comments, quoted or paraphrased, across the disciplines and related to project support include:

- "it gave me confidence that if something went wrong that I knew he [the teaching assistant] was there … Because I've never used it [*MAT*] before" ('VET' teacher-2)
- the technical support offered in the project freed the teacher to think of the pedagogy ('VET' teacher-1)
- any issues, contacted either project leader or teaching assistant employed by project ('Health' teacher-3)
- teachers within disciplines supported each other ('JD', 'Education', and 'Health')
- "clear written instructions would be helpful, [and/or] maybe one on one if someone could sit down with a teacher and show them how to use it" ('JD' teacher-2)
- support to use *MAT* was not available pre-project, then available in abundance during the project when we didn't have time to take advantage of it all ('Education' teacher-1)
- "the whole introduction to *MAT* and the practicalities of it really came from the student teachers or the teacher assistants … It was good for peer support but then I would say a lot of students were perhaps slightly lazy and took advantage of that and didn't learn how to do it themselves and relied on the two [teaching assistants]" ('Education' teacher-2).

Clearly, ongoing technical support for *MAT* is important to participants but this level of support is unlikely to continue due to the finalisation of grant monies.

Future use

One of the positives of the project was the rich reflection of project team members in relation to the future use of *MAT*. Staff reflection identified future applications such as the following:

> I see that this [*MAT*] could be used in a number of ways for effective learning … [and] could be maintained … as an electronic library but I think it's more flexible than that. The students could use this to apply that skill in a particular setting … [plus as a review tool for] revision for the exams, [and] students could use it as a refresher before next year starts so they can revise this content because next year's content extends on this. ('Health' teacher-3)
>
> it's got so much applicability in different contexts, presentations even; even in this [other] program … our students do so many presentations, because that's what they have to do when they go out there in the field. … [My other program] is Criminal Justice Administration, anything with the criminal justice sector but they do a lot of government projects and presentations and we go out, so being able to see what you can do and how, how to sell something, I'd love to use it here. ('JD' teacher-3)

Such creative applications of *MAT* were, however, qualified by the earlier resources concern. For example, one participant reflected:

> Possibly the problem is cost and resources, how will we pay for that in the future... [video and expert time costs] … there are some resources but … I'm worried about the future and … I'm wondering if we should sit with what we've done; do it again and then move next year – just because I think we need to solidify, consolidate. ('JD' teacher-1)

Professional development

Many of the issues emerging from the teacher interviews can inform professional development options for *MAT* integrations in the future. Some of these issues (paraphrased or quoted) include:

Establish purpose:
- evaluate if suitable, as even though it suited my course, *MAT* may not suit all content in all courses (‘Health’ teacher-3)
- “you have to think about exactly why you want to use it and how it’s going to be purposeful for your course and that’s really constantly articulated across to the students.” (‘Education’ teacher-2)

Learning design and student considerations:
- use *MAT* as one tool in amongst other learning strategies, as one part of a total delivery. (‘VET’ teacher-1)
- “Make it a reasonable percentage of your assessment” (‘Health’ teacher-1)
- plan your usage of *MAT*; develop good, clear instructions for the students (‘Health’ teacher-1)
- go beyond a technical focus in training, for example, structure the pedagogical framework of how the students will interact with the video (‘JD’ teacher 1)
- “if it is student’s work that is being presented, they have to really respect each other and respect each other’s work as well, because being critical of each other can be painful and hurtful.” (‘VET’ teacher-2)

Planning process:
- “play with it first, I think have a trial run, and you really need to practice and … think about every single stage … really think about, ‘Okay, what’s going to happen next; planning’, absolutely planning the life out of it so that you’ve got a contingency plan and ... just making sure the students are constantly kept in the loop about the benefits for them and why they’re doing it.” (‘JD’ teacher 3)

Recommended teacher PD approach:
- use modelling and/or champions: “it would be useful for teachers to look at what we’ve done and what has been done in similar projects, to hear some of the really good things and things that went wrong and the different ways that has been used to get ideas.” (‘JD’ teacher-2)
- “work with someone else and also to have confidence in the person or people that need to give you the technical support … it's not only technical support, because technical support without understanding of the tasks you’re doing isn’t worth a great deal. So you actually need people to engage with you and what you are doing so they understand how you are trying to make the technology work” (‘Education’ teacher-1)

Sustainability of project’s focus and outcomes

MAT has progressed through design and development (Stage I: video), pilot integration and evaluation, to multiple-case integration and evaluation across various disciplines in the most recent project. Embedding into university systems and promoting to teachers has been identified as the next step (Gunn, 2010) and options from this project for sustainability or scaling up supports—further supported by literature—include promotion, professional development in innovative teaching and technical training, as well as general ongoing support.

Promotion

Champions are a key factor in promoting and sustaining technological innovations. There is a learning curve involved with the uptake of a new educational technology and creating a culture of use in the institute is important for its acceptance (Breslin, *et al*., 2007). As a result of the 2011 project, there are now ten newly proficient teachers using *MAT* who unanimously recommended this innovation (with some qualifiers) for other teachers to use. These teachers could become champions, however, it takes more than a champion to effect success in technology integration, including “a complex environment that supports change, with engagement from a number of key players, all working together and developing and sharing a common vision or set of goals for the use of technology” (Bates & Sangrà, 2011, p.84). Positive aspects of appointing champions to promote technology also need to be weighed up with risks, such as champions leaving the institute, or evidencing excessive dedication and time to get the technology to work, which might deter others (Bates & Sangrà, 2011). Time commitment was noted as a factor of concern for the project teachers.

Development of models of *MAT* use from the various cases across the project (in-progress) is another planned step to help promote effective use of the tool, by way of offering pedagogical examples. The intention is to explicitly exhibit ways *MAT* was used to support learning in co-dependant visual and textual forms, which can be accessed via the web or during presentations and promotional activities by the ‘champion’ teachers and other training staff. A University of Reading pilot project in learning design (Papaefthimiou, 2012) found that academics needed to critically think about their learning design decisions, reflect on them, and discuss with others. The report identified that success in their pilot required “[r]epresentations and visualisations of courses or modules … to facilitate wider sharing and collaboration … beyond the localised pockets of good practice identified" (Papaefthimiou, 2012, p.28). A caution offered in the report was that stimulation and subsequent generation of innovative learning design ideas can result in more change than can realistically be implemented. In view of that, refinement stages are required within courses to decide what can realistically be achieved.

Professional development in innovative teaching and technical training

As indicated by the project teachers, teaching with *MAT* requires not just technical training, but a significant, integrated pedagogical component as well. Breslin, *et al*., (2007) noted the need for technical training and funding for embedding technological resources in learning, but emphasised the more complex requirement for pedagogical integration to be of learning value. Bates and Sangrà (2011) examined eleven cases of implementation of technology, and found the optimal position for success is where training is provided along with a focus on learning and teaching. They suggested that redesign of the curriculum is required to benefit current student cohorts, rather than simply adding technology to teaching (Bates and Sangrà, 2011).

To help facilitate *MAT* training (including self-training), technical guides have been developed as part of the project. The suite of guides was completed immediately post-project, informed by the student, teacher and support staff experiences with *MAT* across the nine cases of the project. They were peer reviewed in draft by non-project teachers, then reviewed in final version by project teachers. These include two manuals (teacher and student versions), two quick guides, and two video production technical support flyers. The manuals feature case use examples from the project (and from the preceding pilot) to contextualise *MAT* integration options. The guides have been recently uploaded to the web in a first step to meet the goal to provide "staff, students, and faculty access to information and services easily over the web" (Bates and Sangrà, 2011, p.72). To help facilitate a re-think on teaching involving *MAT*, models of *MAT* use are under development for eventual sharing across the academic community. One such model is already on offer from the 2009 pilot study (Colasante, 2011a; Colasante 2011b), with up to nine models to follow from the multiple-case study to demonstrate various possible approaches and to stimulate new application ideas.

Ongoing support

The data indicates that the success of the *MAT* project in 2011 was dependant on a number of issues, including resource and technical support. However, this level of support is unlikely to be provided by the university into the future as the grant provided a temporary injection of funding. A key positive outcome of the project was the gathering of interested and committed staff to apply *MAT* in new contexts. This group have developed an informal community of practice (Lave and Wenger 1991), and have shared ideas and identified new applications of this unique tool. Further, Owen and Davis (2010) summarised the nature of organically emerging communities of practice as self-sustaining but noted that some sort of formal leadership can add benefits, such as formalising support as needs arise. Indeed, Kran (2010) recommended communities of practice as "the best place to sustain project outputs". The *MAT* communities of practice that formed project-wide and intra-project were valuable for support while the project was active, but have been ad hoc since, although as Kran pointed out, "[s]ustainability does not mean forever; it can mean long enough."

Ongoing maintenance and cost issues are an important concern emerging from the data. According to Bates and Sangrà (2011), teaching technology should be adequately funded as a core rather than desirable activity, and that funding should include identification and budgeting "for the real cost of training faculty and instructors to use technology effectively." (p.93). They pointed out that:

> [w]here these projects operated in isolation of a more general strategy for technology integration, or were the initiative of a single senior administrator, they were more likely to fail or at least to restrict the extent of technology integration within the institution … Thus, while specific projects can be valuable, at the same time it is important to establish ongoing and permanent structures to support technology integration. (Bates and Sangrà, 2011, p.110-111)

Conclusion

The data analysed in this paper shows that *MAT* can be sustainable in the future if a number of strategies are adopted, aligned to the third Gunn (2010) condition of sustainability related to wider uptake and embedding into institutional systems. Firstly, the community of practice established through the LTIF project in 2011 needs to be nurtured and encouraged through continued meetings, with widening participation, sharing of ideas and collective writing. Participants in a continuing community of practice will benefit from reflections about what is successful and what needs fine-tuning in the use of *MAT*. Additionally, several of the project teachers have continued to use *MAT* in their courses in 2012; some have also integrated it into additional courses, and others are planning integration into alternative courses with a better understanding of how *MAT* supports various learning approaches. Importantly, some also intend to continue to evaluate *MAT*'s effectiveness, which will feed back into further understanding.

A notable concern from the data was the sustainability of *MAT* given the cessation of funding with the completion of the 2011 grant, and how the university systems might fill the void. Some of the teachers in the project required technical support in order to successfully implement *MAT*. Other teachers and students were able to quickly adopt *MAT* due to established technical ability and intuitive responses to the tool. As noted, a suite of guides has been produced, informed by the experiences of the multiple-case study and with case examples embedded in order to assist with the use of *MAT* into the future. While these should aid in the issue of reduced support to project teachers post-project, plus help those who are new to *MAT*, they will need updating as the tool matures. The various models of *MAT* use will be progressively available. In another issue of sustainability, this model formalisation process is currently reliant on post-project, spare-time commitment from project team members, with all funding and work-plan support since exhausted. Additionally, practical support for video production, in the form of technical support and/or equipment, needs to be considered on a larger scale as more teachers integrate *MAT* into their curriculum.

The full case models (in development) and the guides (completed) will be available to support further use of *MAT* in the university, and as new products, these will be open to further (post-project) evaluation. Also university IT department staff can be trained in the use of *MAT* to provide a level of ongoing support to those staff and students who require detailed support. These two approaches will assist with the sustainable future of *MAT* and ensure the ongoing experimentation and development of this innovative learning tool. The overall benefits of *MAT* in providing a tool for engagement and reflection in a variety of disciplines can be sustained with the continued good efforts of staff with various skill sets across the university and the acceptance and uptake by teachers and students.

From this research, a number of papers are in progress on specific discipline and/or sector applications, including detailing the student experiences. Future research directions beyond this will depend upon *MAT*'s sustainable growth within and beyond the university.

Mediated learning in the workplace: Students' perspective on present and future value of knowledge tools

Madeleine Shanahan
RMIT University

Work-integrated learning is an essential component of many university degrees. This study examined a range of knowledge tools that are used by students to support their learning during clinical placement. This study showed that expert others in the workplace, print and electronic information sources and to a lesser extent electronic communication tools were utilized by students during their clinical placement to support their learning. The finding support an integration of practice-base learning with learning mediated by information sources to provides further understanding of work-integrated learning

Keywords: workplace learning, mediated learning, knowledge tools, information sources

Introduction

Universities in Australia and internationally have integrated Work-integrated learning (WIL) into programs of study. WIL provides tertiary learners with real world experiences that support the integration of theory with the practice of work (Patrick et al., 2008). This repositioning of learning experiences from university settings into workplaces harnesses the benefits of practice-based models such as communities of practice (Lave & Wenger, 1991) and workplace learning (Billett, 1994, 1995). These models posit that learning occurs through enculturation into practice with a central role afforded to workplace participants who are more experienced, wiser or more knowing, such as 'old timers' and 'more experienced others', sharing their knowledge and experience with learners or 'new comers' during everyday workplace activities. What remains hidden in such models is the importance of other knowledge tools to student learning that occurs in the workplace.

Information sources have an important role in learning. According to Engeström and colleagues (1984) learning "is mediated above all by … knowledge, initially embedded as material tools" (p.140) of information sources. Brookfield (1985) concurs explaining that books and educational broadcasts were "all devised by humans for the purpose of facilitating skill development or knowledge acquisition" (p.7). Across professions seminars, journals and health and medical databases are considered essential tools for learning proving access to new discipline knowledge (Garvey, Lin, Nelson, & Tomita, 1972; Keppell et al., 2001; Shanahan, 2011, 2012). The Internet has also been recognized as an important information source offering immediate access to the most current information through web sites of professional, government, education and commercial organisations (Herrington & Herrington, 2006; Shanahan, Herrington, & Herrington, 2009). Not only local experts sharing their knowledge during workplace activities mediate student learning in the workplace but also there are multiple information sources that similarly could mediate student learning in the workplace. In addition, communication tools such as email provide learners with access to experts and other learners across the world and support knowledge construction through articulation and reflection (D. Jonassen, Howland, Marra, & Crismond, 2008; D. H. Jonassen, 2000). This research sought to examine the perceived importance of workplace experts and information and communication tools to students for their present and future learning. The term knowledge tools is utilized in this study to encompass experts in the workplace sharing their professional knowledge (Eraut, 1994; Higgs & Titchen, 2001; Lave & Wenger, 1991), information sources that disseminate discipline knowledge (Eraut, 1994; Higgs & Titchen, 2001) and communication tools that support knowledge articulation and construction (D. Jonassen et al., 2008; D. H. Jonassen, 2000).

The study

Context

Clinical work placements are an essential component of professional health-related degrees with requirements linked to Program accreditation requirements (Patrick et al., 2008). The health area of the professional degree in this study is Radiography and like other health professions, the clinical placement is an essential element to meet Program accreditation requirements (Australian Institute of Radiography, 2010). The students were in the second year of the Program of study and attended a six-week block of clinical practice.

Research questions

The research questions were:

1. What knowledge tools are utilised by students to support their learning during clinica placement
2. What importance do students' attribute to a range of knowledge tools to support their learning whilst on clinical placement.
3. What value do students' attribute to these knowledge tools for learning as a future health professionals

Methodology

An anonymous questionnaire was distributed to 62 students following completion of their clinical placement. A range of knowledge tools was examined (see Table 1). Descriptive statistics were utilised to determine use of knowledge tools during clinical placement to support learning. A five point likert scale (e.g. 1 *very important* – 5 *not important*) was utilised to collect data on present importance and perceived future value of these knowledge tools for learning in the workplace. The survey data were entered into SPSS 17.0 ® and the Friedman Test (Pett, 1997) was performed to determine student overall ranking of knowledge tools for current and future learning in the workplace. Ethics Approval for this study was granted from RMIT University.

Results and Discussion

Of the 62 surveys distributed, 53 useable surveys were returned. The majority of students (68%, n=36) attended a clinical placement in a metropolitan location. The remaining students attended workplaces in regional (n=7) or rural (n=10) locations. Sixty percent (n=32) of students attended a public sector workplace, with the remaining 21 students undertaking clinical workplaces in the private sector.

Use of knowledge tools during workplace learning

Survey respondents were asked to identify the knowledge tools that they utilised during their work placement to support their learning. Percent and number of respondents that reported using the knowledge tool to support their learning during their clinical placement is displayed in Table 1.

Table 1: Use of knowledge tools to support workplace learning

Knowledge Tool	Percent [a] (No)
Text and reference books	96 (50)
Internet	94 (49)
Workplace experts	92 (48)
University E-resources	80 (40)
Email	72 (36)
Workplace Intranet with learning resources	71 (37)
Electronic journals	50 (26)
Health and medical databases	48 (25)
Print journals	46 (24)
Social discussion forums e.g. Facebook, Twitter	42 (22)
Seminars in the workplace	39 (20)
Journal club	28 (14)

[a] Percentages are based upon number of respondents answering each question

Students utilised a range of knowledge tools to support their learning during clinical placement. Eighty percent or more students utilised textbooks, Internet, experts in their workplace and University e-resources during clinical placement. Workplace Intranets providing access to clinical guidelines and journal articles were also utilised during clinical placement to support learning. In relation to journals both print and electronic were used by students to support their learning. The students also used email and social discussion forums to support their learning whilst on clinical placement. These findings highlight the high level of use of expert others as well and digital and non-digital information sources during clinical placement.

Current importance of knowledge tools during workplace learning

Students were asked to rate on a scale from 1 (very important) to 5 (not important) a range of knowledge tools that may be used to support their learning during clinical placement. A Friedman Test was conducted on this data to obtain an overall ranking of the importance students' attribute to these tools for learning. The ordered ranking is presented in Table 2.

Table 2: Current importance of knowledge tools during workplace learning

Knowledge Tool	Mean Rank
Workplace experts	3.16
Text and reference books	3.55
Internet	3.99
Workplace Intranet with learning resources	5.71
University E-resources	5.92
Email	6.87
Seminars in the workplace	7.42
Health and medical databases	7.50
Electronic journals	7.60
Print journals	7.84
Social discussion forums e.g. Facebook, Twitter	9.10
Journal club	9.34

Difference in ranking was observed across the examined mediating knowledge tools. The observed difference in ranking was statistically significant $\left(\chi^2 = 185.643, df = 811 p \leq .001\right)$. Thus indicating that value attributed to the examined knowledge tools for mediating learning during clinical placement was not homogenous. For example, students ranked workplace experts as having the highest importance for learning during clinical placement. This finding is in agreement with practice-based models of learning that posit that learning occurs through expert others sharing their knowledge and experience with learners or 'new comers' during everyday workplace activities (Billett, 1994; Lave & Wenger, 1991). Books, the Internet and workplace Intranets that provide learning resources such as practice guidelines, journal articles and University e-resources were ranked the four next highest respectively for supporting learning in the workplace. This finding indicate that these information sources are also of high importance to students and suggests that students are as Patrick and colleagues (2008) contend integrating theory with the practice of work during their clinical placement. The findings also highlight the importance of people with expert knowledge, digital and non-digital information sources to student learning during workplace practicum. It is also apparent that students place different level of importance to communication tools with email ranked more highly as supporting learning than social discussion forums such as facebook. This may reflect students' differentiating their preferred use of these tools between learning and socialising.

Perceived future value of knowledge tools for workplace learning

Students were asked to rate on a scale from 1 (very valuable) to 5 (not valuable) the future value of the listed knowledge tools to them as future health professionals. A Friedman Test was conducted on this data to obtain an overall ranking of the value students' attribute to these tools for their future learning. The ordered ranking is presented in Table 3.

Table 3: Future value of knowledge tools for workplace learning

Knowledge Tool	**Mean Rank**
Workplace experts	3.85
Internet	3.98
Text and reference books	4.45
Workplace Intranet with learning resources	5.15
Seminars in the workplace	6.15
University E-resources	7.24
Email	7.49
Electronic journals	6.49
Health and medical databases	7.26
Print journals	7.35
Journal club	8.39
Social discussion forums e.g. Facebook, Twitter	10.20

Difference in ranking was observed across the examined mediating knowledge tools. The observed difference in ranking was statistically significant $\left(\chi^2 = 218.508, df = 11 p \leq .001\right)$. Thus indicating that perceived future value attributed to the examined knowledge tools for mediating learning as health professionals was not homogenous. Workplace experts, Internet and textbooks were again ranked the top three knowledge tools, although there was some slight reordering of ranking between current importance (Table 2) and future value of these tools. Seminars were ranked fourth highest in value as a knowledge tool for learning as a health professional. This ranking of seminars was higher than it was ranked for current importance (seventh, Table 2) suggesting that students are aware of the importance of seminars to health professionals for their continued learning (Garvey et al., 1972; Keppell et al., 2001; Shanahan, 2012). The recent study by Shanahan (2012) demonstrated that health professionals ranked seminars as the most important information source for updating their professional knowledge. A finding that was in accord with the earlier study by Keppell and colleagues (2001). As only 39% of students attended a seminar whilst on clinical placement, the majority of students may not yet appreciate the important role seminars have in professional learning. It was interesting to observe that University e-resources were still valued by students as knowledge tools for their future learning. Cole (2001) identified that university resources such as journals had become less accessible to health professionals as electronic journals required login access typically restricted to student and staff of the university, whereas print-based journals could be accessed by any health professional who could physically attend the university library. The continued relatively high ranking of university e-resources for future value for learning may reflect a naivety that these resources will still be able to be accessed and used after completing their program of study. The findings also highlight the perceived value students' attribute to people with expert knowledge, digital and non-digital information sources for their future learning as health professionals.

Implications for learning theory

This study examined knowledge tools that support learning during workplace practice. Practice-based models such as communities of practice (Lave & Wenger, 1991) and workplace learning (Billett, 1994, 1995) posit that other participants in the workplace who are more experienced, wiser or more knowing such as 'old timers' and 'more experienced others' are essential to the process of transforming learners from novice to competent practitioners in their field. The findings from this study are supportive that expert others in the workplace do have an important role in facilitating learning during clinical placement.

It is also apparent that information sources have an important role in workplace learning. When learning is theorised as an activity mediated by tools (Vygotsky, 1981), information sources become cognitive tools supporting active, intentional knowledge construction (Hill, Wiley, Nelson, & Han, 2004; D. H. Jonassen, 2000). Information changes learners' knowledge in two ways. Information adds factual knowledge (Todd, 1999, 2006; Tynjala, 1999). This type of learning with information sources was termed in-*form*-ative by Kegan (2009) to denote its role in bringing valuable new content that is essential to ensure mastery in the learners field or discipline. Information sources such as books and journals provide the principles or theories, the 'know why' as well as domain content, the 'know what' of professional knowledge (Eraut, 1994; Tynjala, 1999).

Information can also change the way the learner knows and become what Kegan (2009) calls trans-*form*-ational.. In this case, the information does not just expand an already existing knowledge framework but the framework itself is reconstructed or changed (Illeris, 2009; Kegan, 2009). The process of reconstruction can involve linking previously unconnected concepts (Illeris, 2009; Todd, 1999, 2006) deleting previously held understandings and accepting something that is new or different (Illeris, 2009; Todd, 1999) and thinking about the information such as coherency of facts and bias of authors (Kegan, 2009; Todd, 2006). Whilst informative learning is portrayed in an increase in quantity of knowledge (Kegan, 2009), transformational learning suggests an increase in the quality of knowledge (Dole & Sinatra, 1998). Research differentiating novices' and experts' knowledge has shown that experts' knowledge is more detailed and comprehensive (high quantity) with higher levels of coherence, discrimination, relationships and generalisations (high quality) than novices' knowledge (Barba & Rubba, 1992; Bryce & Blown, 2012; Chi, Feltovich, & Glaser, 1981). Thus both informative and transformative learning with information sources is necessary for developing and maintaining expert knowledge in the learner's discipline area. Learning with information sources is always more than just the individual, it is person-plus (Perkins, 1997). The person-plus may include the individual learner plus the information source and their new understanding. Learning mediated by information sources, from this perspective is conceptualised as an individual mental process, such as in cognitivism (Candy, 1991; Jarvis, Holford, & Griffin, 2003; Merriam & Cafarella, 1999). Alternately, person-plus may expand to many learners, their shared learning opportunities plus the information source. From this conception, learning expands beyond the individual's mind and may include shared learning across participants such as in constructivism (Candy, 1991; Hill et al., 2004; D. H. Jonassen, 2000). In this current research students were shown to engage with information sources both on an individual and shared learning basis. On an individual basis, students read books and journal articles, searched the Internet and health and medical databases for needed information to construct their knowledge. Students also engaged in shared learning activities through discussion with expert others, utilising communication tools and participating in journal clubs. Together these activities provided students with opportunities for accessing new information as well as opportunities for articulating and sharing their learning with others.

Conclusion

Work-integrated learning is an essential component of many university degrees. By examining the knowledge tools that are utilised during this activity, which included expert others, and information sources, this research provides valuable insight. The findings from this research support an integration of practice-base learning, where the focus is on expert others and the role they play in facilitating learning in the workplace (Billett, 1994, 1995, 1999; Lave & Wenger, 1991) with learning mediated by information sources (Hill et al., 2004; D. Jonassen et al., 2008; Shanahan, 2011, 2012). This integrative approach provides further understanding of work-integrated learning by recognising the importance of both expert others and information sources to learning that occurs during clinical placement.

Building an Institutional Reporting Framework for Consensus Moderation Practices

Nicola D. Shapland
Griffith Institute for Higher Education
Griffith University

Duncan D. Nulty
Griffith Institute for Higher Education
Griffith University

This poster presents the initial findings from a two year Griffith University research project. The project entitled "*Developing consensus moderation practices to support comprehensive Quality Assurance of Assessment Standards"* is funded through a strategic Griffith Grant for Learning and Teaching, with ethical approval granted under reference number GIH/08/11/HREC. The poster describes the development of, and reports on the initial results from, applying a five level model of consensus moderation to assessment. Each level in the model describes a key stage in the assessment process, and a range of consensus moderation practices that would support quality assurance of assessment at that level. The reporting framework is imbedded in the University's online Course Profile system and requires academics to report on their consensus moderation activities. Initial results confirmed this to be a meaningful reporting framework to gather and evaluate consensus moderation activities in use throughout the University.

Keywords: consensus moderation, reporting framework, quality assurance of assessment

Building a Consensus Moderation Reporting Framework

Qualitative in-depth interviews held with academics in the scoping phase of the project revealed that many are engaging in a range of moderation activities. The initial picture presented of a lack of consistent moderation practices was due in part to the lack of consistent language used; which in turn made identifying and reporting in a meaningful way impossible to date (Nulty 2011a). The development of a framework and common understanding throughout the academic community on the meaning of, and practices consistent with, consensus moderation of assessment was required. Building on Sadler's work on moderation and quality assurance of achievement standards (Sadler 2009, 2010), a multi level model was developed to identify and describe the stages in the assessment process at which consensus moderation should apply (Nulty 2011b).

A mapping exercise was then undertaken to map consensus moderation practices identified in the scoping interviews with the different stages of the assessment process described in the model. This approach of identifying and categorising existing consensus moderation activities created a model that was acceptable and sustainable for academics. Academics 'recognise' moderation activities they already engage in, as well as being exposed to ideas to further develop their moderation practice. A five level consensus moderation model was finally approved and adopted by the University, supported by incorporation in the University's Assessment Policy.

This consensus moderation model then provided the vehicle for constructing a meaningful reporting framework against which Schools and the University could report on the consensus moderation activities they use. The University's online Course Profile system was the platform in which the reporting framework was imbedded. Course Convenors are required to complete and submit a Course Profile (the official and public University document) for each course, each semester. From Semester 1, 2011 the Course Profile document included a section on consensus moderation practice as part of its curriculum initiatives tracking system. Convenors are required to identify the consensus moderation practices used in their courses via ticking checkboxes next to descriptions of practice. The descriptions of moderation practices are consistent with and aligned to all five levels of the University's approved Consensus Moderation Model.

Results

The reporting framework was first included in the Course Profile system for use in Semester 1, 2011. Data was able to be collected showing the % of academics that engaged in some form of moderation of assessment across each level of the University's approved Consensus Moderation Model.

Table 1: The Use of Consensus Moderation Practices across 5 Levels of the Assessment Process

Consensus Moderation Level	% of Academic Use in Sem 1, 2011
Level 1: Course Level Assessment Planning	95.41
Level 2: Marking Student Work	92.25
Level 3: Grading Student Work	91.47
Level 4: Standards Across Courses	62.77
Level 5: Standards Over Time	71.73

Conclusion

The Institutional Reporting Framework for Consensus Moderation Practices allows data on consensus moderation practices to be systematically collected for the University for the first time. Initial results revealed that academics were able to successfully record their consensus moderation activities; allowing the University to collect Institutional data to evidence support of quality assurance of assessment and academic standards.

Emerging strategies for a sustainable approach to professional development

Kuki Singh
Curtin Teaching and Learning
Curtin University

Judy Schrape
Curtin Teaching and Learning
Curtin University

Jacqui Kelly
Curtin Teaching and Learning
Curtin University

Recent elearning trends in higher education are unleashing non-traditional professional development strategies. Employing a pragmatic approach to research, an evolving evidence-based practice within an Australian university is examined to establish a set of guidelines for sustainable professional development practices. A combination of traditional and non-traditional professional development strategies are described and staff participation and strategic impacts are analysed. Whilst current initiatives demonstrate good practice in terms of approach, strategies, contexts, content, and quality indicators, incumbent challenges include a demonstrated preference among staff for traditional workshops, voluntary participation which contributes to uneven elearning development, and the absence of formal follow up on transferability of skills and impacts. The study concluded that a purpose driven, multi-dimensional professional development approach that is embedded across all layers of the organisation advances sustainability. Six design principles are proposed for the achievement of sustainability within a centralised professional development service at an Australian university.

Keywords: elearning, professional development, sustainability.

Introduction

Approaches to professional development in higher education is increasingly influenced by evolving models of teaching and learning, impacted by trends in technology. Four significant technology trends are extended access to educational resources; relationships supported by the ease of internet access; the expectation to be able to study anywhere, anytime facilitated by advancements in mobile technologies; and the capacity to learn in collaborative and engaging online spaces with rich resources using social media and cloud based technologies (Johnson, Levine, Smith, & Stone, 2010; Johnson, Smith, Willis, Levine, & Haywood, 2011). Staff development challenges associated with these trends are the expectation for staff and their students to be digitally literate; for staff to acquire the skills to work effectively within models of education that have emerged from the economic pressures of the last decade (e.g., large classes, diverse cohorts, multiple study periods, offshore partnerships, multiple delivery modes); for staff to keep pace with the proliferation of information, tools and devices integrated within learning environments; and for staff to understand and apply new metrics of evaluation in their work. These challenges are further compounded when the time pressures academics already face are factored into achievement of the common goal of effecting change in understanding, practice and beliefs in technology integrated environments (OECD, 2009; Wells, 2007). Such conditions are driving efforts to obtain new and sustainable ways of approaching staff development in higher education environments.

In this paper we examine our response to these trends to bring about sustainable change in knowledge, skills and attitudes amongst staff, with the use of non-traditional professional development strategies to complement a long standing traditional approach. Whilst 'leading in a climate of change' we analyse the sustainability of these emergent professional development strategies and extract a set of design principles to guide our future work.

Sustainability in professional development and learning

We take a broad perspective on sustainability in our work practice by examining the strategies we employ to promote staff engagement in elearning development that reaches beyond once off training and proof of concept teaching development projects to achieve change that is both strategic and embedded. To fully conceptualise our approach, we draw from three related concepts: professional development, professional learning and sustainability.

The terms professional development and professional learning, although often used interchangeably in the profession, are differentiated in the literature. Authors such as Little (1999) and McLaughlin (1994) suggest that professional development refers to something that one 'does', or that 'is provided', or is 'done to' staff. It involves both formal and informal activities that "engage teachers or administrators in new learning about their professional practice" (Knapp, 2003, p. 112), and includes "activities that develop an individual's skills, knowledge, expertise and other characteristics" (OECD, 2009, p. 49). This traditional approach is generally associated with generic workshops and in-service training, and has attracted much criticism for being fragmented and decontextualised. The use of the term professional learning signals a shift in thinking, as Knapp elaborates, "it refers to changes in thinking, knowledge, skills, and approaches to instruction that form . . . teachers' or administrators' repertoire" (pp. 112-113). This shift signals changes in one's capacity for practice or changes in one's practice itself. We are mindful of the shifts in thinking denoted by these terms and embrace the new directions within our work. To this end, Day and Sachs' (2004), Wells' (2007), Grant's (1996) and Applebee, McShane, Sheely and Ellis' (2005) explanations provide us with a cohesive conceptual understanding. We view professional development as encompassing formally planned and naturally occurring activities that staff may engage in collaboratively or independently, to acquire and develop ideas, knowledge, skills, attitudes and practices that bring about change in their work and foster inquiry-based learning within a supported environment. Therefore, our view of professional development is responsive to the shifts in thinking represented in the literature, and is articulated in our interchangeable use of the terminology within this paper. Our use of the term sustainability broadly refers to the capacity to achieve durability in practice. Our primary consideration of sustainability is from the perspective of achieving shifts in knowledge, skills and attitudes that contribute to lasting change in technology integrated teaching and learning practices. Additionally we consider sustainability in terms of our approach to addressing staff needs and institutional priorities in a timely and resource efficient manner.

We contend that our approach aims to reach beyond traditional professional development strategies that typically involve one-off workshops with limited continuity or contextualisation based on a model of expert-to-novice knowledge and skills transfer. Such an approach offers limited sustainability with its focus on 'just in time', discrete improvements in practice focused largely on individuals, making it resource intensive compounded by scheduling difficulties and low participation (see Kelly, Singh, & Schrape, 2011). In fact, the Westchester Institute for Human Services Research (2012) claims, "such conventional forms of professional development have little effect on educator practices, organizational changes, and student outcomes" (para. 9), raising concerns over strategic impacts and sustainability.

Our approach to professional development and learning aims, therefore, to strengthen links to classroom practices; create ongoing, self-directed and collaborative opportunities for staff to engage in elearning developments; to keep abreast of emergent trends in educational technologies to promote innovative pedagogies; and to enhance research led teaching. This aligns our approach to professional development and learning to some of Hawley and Valli's (1999) influential design principles. The strategies we employ incorporate contemporary approaches such as teacher networks, joint networks, collaborations, action research, mentor programs and peer coaching, as we believe these address complex and multifaceted needs, including that of strategic and sustainable practice.

Approach to the design of professional learning and development

Given the multiple layers of elearning development strategies that have evolved in our practice, we sought an approach that would allow us to derive evidence-based claims about our work. A design based approach was considered suitable as it would enable us to develop a set of principles to guide our practice in iterative cycles (Barab & Squire, 2004). Additionally, this was a preferred approach because it allowed us to address the messiness of real-world practice, recognise the influence of the local context including the multiple dependent variables, and capture the social interactions in which our work is embedded. Most importantly, it values the staff as participants who contribute to the design and evaluation of our practices (Collins, 1999).

This approach enabled us to situate our analysis and reflection in the local context, enabling us to theorise our work by focusing on contextual aspects including staff participation data and our responsiveness to elearning developments, and to uncover a set of guidelines for future work.

Professional development strategies

The complex organisational nature of universities, accompanied by evolving pedagogies, requires multiple professional development strategies to effectively address needs, respond to emerging trends in teaching and learning and facilitate improvements. We 'push' information out to staff by modelling the use of web 2.0 technologies, and we 'pull' staff in through traditional workshops. Our group and project learning strategies combine both approaches. Our use of a combination of 'push' and 'pull' strategies converge to contribute to strategic teaching and learning goals. However, it is problematic to demonstrate a direct link between the professional development opportunities we offer and teaching and learning enhancements (Ingvarson, Meiers, & Beavis, 2005; Meiers & Invarson, 2005). At best we claim a convergence across these areas, evidenced consistently through *e*VALUATE, the university's online system for gathering and reporting student feedback on teaching and learning experiences, and CASS, the Curtin Annual Student Satisfaction Survey data on students' elearning experiences.

e-Newsletters

Electronic newsletters are published monthly in a university blog as well as via a broadcast email to all staff. Topics on emerging educational technologies and their pedagogical applications are strategically selected to raise awareness and stimulate interest among staff. Typically a member of the elearning team volunteers to draft a newsletter on a topic of interest, and the document is then developed collaboratively. To date we have produced 32 e-newsletters on topics ranging from *Using Skype in Education* to *Interactive Rubrics*. Anecdotal feedback from staff suggests this is a highly valued professional learning resource, providing timely information throughout the semester. The collection of e-newsletters is located at: http://blogs.curtin.edu.au/cel/category/cel-newsletter/ and is available beyond the university. Pushing out information and teaching tips in this way, provides an ongoing source of professional learning designed to raise staff awareness, knowledge and skills about teaching with technology issues. Modelling the use of the blog tool tacitly promotes staff engagement with web 2.0. The e-newsletters also serve the strategic purpose of raising the profile of the Centre and its services, mainstreaming elearning. We find this a sustainable strategy as it strengthens team collaboration, disperses the workload, and generates university wide reach in an efficient and effective manner.

Curation – *Scoop.it*

The recent increase in the rise of content aggregation tools has provided new opportunities to quickly and easily organise, summarise and share (republish) information on topics of interest. One such tool currently being trialled at Curtin is *Scoop.it* (http://www.scoop.it/), which offers a magazine style layout of curated topics. Users are permitted to publish up to five topics at no cost, and our subscription at a nominal monthly cost permits the creation of up to 20 Scoop.it topics.

To integrate and facilitate adoption of cloud-based curation tools we are increasingly embedding curated topics within related professional learning resources made available via our website. In the first two months of adoption we are managing 14 topics and we have received over 14,300 views since adoption mid April 2012, with an average of 140 views per day. Our curated topics include current interests in *Mobile Learning in Higher Education*, *Learning Analytics in Higher Education* and *Open Educational Resources*. Curation offers a dynamic and flexible means of extending our professional learning offerings within and beyond the university, making this a sustainable team based strategy that we use to strengthen a range of existing resources, and simultaneously generate interest and build knowledge in current educational trends.

Website Resources

The Curtin Teaching and Learning website (http://ctl.curtin.edu.au) is an information hub where staff can access resources and information. Resources focused on good practice guidelines and tips addressing e-pedagogy, learning technologies and using *Blackboard*, are updated regularly. Information and access to projects, policies and documents, services and news and events are provided. Local case studies are showcased in a gallery area as a further strategy for advancing good practice in elearning. The strategic direction to develop our initiatives in particular areas has meant that we have shifted to tapping into *Blackboard* resources supplied by external providers, as well as continuing to develop 'home grown' tip sheets focused on e-pedagogy. This has enabled us to extend the range of resources to include video and tip sheets covering a wider range of topics, thus adding to sustainability in our practice. The website receives between 3,000-6,000 unique visitors every month, making it a vital professional learning resource for staff. The continuous process of managing the website is highly sustainable as we utilise the web development expertise available within the team, and all team members contribute to content generation and updating of materials.

University-wide Workshops

An extensive workshop program is run throughout the year. The hourly sessions mainly cover topics designed to develop effective use of *Blackboard* and other integrated technologies. The number of workshops offered for the last three years is as follows: 2010 = 165 (75 + 90); 2011 = 162 (74 + 88); and 2012 = 89 in semester one. All sessions are facilitated by two elearning advisors. Staff self-enrol into sessions using an online booking system. Participant numbers are capped at 10 to allow for small group discussions and hands on practice with the relevant technologies (see Kelly, et al., 2011). The range of workshop offerings and attendance figures during Semester 1 2010, Semester 1 2011 and Semester 1 2012 are supplied in Figure 1.

	Introduction to Blackboard	Managing Assignments	Grade Centre	Blogs, Journals, Wikis & Podcasting	Echo 360 - Personal Capture	Elluminate /Bb Collaborate	Tests and Quizzes	FOLT Module 7	Communication & Collaboration	Other workshops	TOTAL
S1 - 2010	119	20	32	69	29	47	0	22	0	13	351
S1 - 2011	84	42	97	30	31	35	4	35	16	13	387
S1 - 2012	103	77	41	40	21	39	19	19	24	39	422

Figure 1: Semester 1 workshop attendance figures over three years

The workshops continue to attract a relatively large number of staff demonstrated by first semester figures for 2010, 2011 and 2012 reaching 351, 387 and 422 respectively. This reflects a participation rate of between 10-12% of Curtin staff (n = approximately 3500). We consider this a reasonably good reach given that less than half of all staff have a teaching responsibility and so the workshops would hold no interest for them. However, the pervasiveness of technology integration across most areas in the university, is contributing to increasing numbers of non-teaching staff attending some of these workshops to further develop their knowledge and skills.

An evaluation survey of the workshop program is undertaken each semester to gauge staff satisfaction. Although participation rates in this survey are relatively low (2010 = 21.7%; 2011 = 26.1%; 2012 = 27.3%), the data provides a snapshot of staff attitudes and the perceived value of this strategy. We attribute the low participation to survey fatigue, timing of the survey, and staff workload issues (see Kelly et al., 2011), and we are cautious not to generalise the high satisfaction results to the population as a whole. Semester-on-semester data for three years supplied in Figure 2 show high overall satisfaction levels drawn from combined ratings of 'good' and 'very good' (2010 = 79%; 2011 = 96%; and 2012 = 90%).

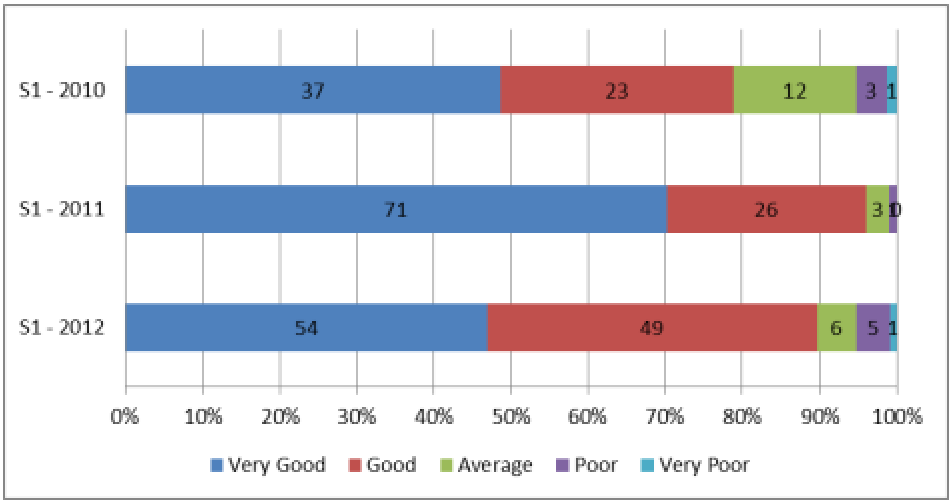

Figure 2: Satisfaction level with workshops attended

Respondents' perceptions of the level of support received (2010 = 89%; 2011 = 86%; 2012 = 83%), and e-pedagogy knowledge gained (2010 = 64%; 2011 = 86%; and 2012 = 87%) was consistently high with an exception in 2010. The latter is likely attributable to the focus on supporting staff to become familiar with integrated web 2.0 technologies as well as developing proficiency in a virtual classroom environment.

The above mentioned evidence suggests that despite being a traditional approach against which much criticism is levelled in the literature, workshops continue to be a much subscribed to professional development strategy at the university, possibly associated with traditional perceptions about 'training' and 'PD' among staff. Despite the criticism that the workshop strategy tends to focus on teaching discrete skills and techniques that fail to accomplish sustained change in teaching practice (Wells, 2007), its usefulness for delivering certain types of information (e.g., when rolling out new technologies) is proven (Little, 1994 as cited in Wells, 2007). However, unlike some of our other professional development strategies, workshops are resource intensive as we offer in the region of 80-90 workshops per semester, each one facilitated by one or two staff. Added to this, attendance patterns and learning needs vary throughout the semester making the workshop program a significant component of our day-to-day workload during teaching periods. They require constant updating of resources, and maintenance of the *Blackboard* training units used for hands-on practice in these lab based workshops. However, staff expectation, satisfactory participation rates, high overall satisfaction and increasing interest among non-teaching staff mean that this is likely to continue to be a core strategy. Criticisms against the conduciveness of this strategy for integration and adoption of new knowledge and skills (e. g., Wells, 2007) are partially mitigated by the complementary strategies emergent within our approach.

Departmental/School Based Workshops

Presentations and workshops are also run for Faculties, Schools and Departments on request and this strategy is particularly useful when rolling out new learning technologies, or upgrading systems. The number of workshops per semester varies from 8-12 with staff attendance ranging from 40 to 84, based on data from the past three years. With representation from Schools across all faculties and more recently non-teaching areas (e.g., the Library and Student Central) as well, this is potentially a powerful means of offering contextualised professional development with reasonably good 'reach,' further demonstrating the impact of our services across the university.

Providing professional development to local environments offers two significant benefits. First, it facilitates greater contextualisation enabling us to more effectively target and address specific needs. Second, it is more likely to generate collegial support and mentoring among staff, with 'early adopters' or more experienced users providing leadership and guidance within specific teams. This strategy facilitates customisation, combatting the limitations of decontextualised offerings. Also, the fact that this is a group based strategy means that we not only reach larger numbers of staff, but also that the potential for cooperative and collaborative engagement within disciplinary based communities is enhanced, all of which make this a sustainable alternative to university-wide workshops.

Communities of Practice

'Communities of practice' are a further professional learning strategy we implement. Borrowing from Wenger (2006), these initiatives strive to "facilitate knowing and learning" to improve practice. Three characteristics apply to this professional learning strategy – (1) The groups have an identity defined by a common interest; (2) Members engage in joint activities and discussions to help each other and share information; and (3) Members are a group of practitioners who develop a shared repository of resources, experiences and ways of addressing recurring problems (Smith, 2003, 2009; Wenger 2006). Building and sustaining relationships among staff across areas of the university and pooling expertise to pursue common interests drives this strategy, making it a sustainable professional learning strategy as the community supports each other in problem solving, sharing information and experiences, reusing assets, harnessing synergy through coordination of efforts, activities and developments, documenting processes, mapping knowledge and identifying gaps, as proposed by Wenger.

The iPad Users Group is one of our communities of practice. Initiated and facilitated by members of the elearning advisory team, this group aims to create a forum for collective learning. An initial meeting was held in March 2012 as a catalyst to bring together as many interested people as possible to share information, ideas and resources on using iPads. A self-sustaining learning group was established to facilitate networking among staff on a variety of topics and issues and a *Blackboard* community space was created to support the group. To meet the diverse needs of the community, multiple interest groups were established with the facility for users to self enrol into the following groups: 'Absolute beginners', 'App development', 'Managing multiple iPads', 'Mine's not an iPad', 'iBooks', and 'iPads in education: Resources, apps, ideas.' The site also provides a range of resources, tips and tricks. In its first week, the community grew to 50+ members and six months later it has reached 227 members. Again, borrowing from Wenger (2006), the iPad Users Group is a collection of people "who share a passion for something they do and they learn how to do it better." Through their regular interactions, they make professional learning a self-driven activity demonstrating the viability of this as a sustainable practice.

The elReps group is our second community of practice. Similar in its purpose to the iPad Users Group, this group, also initiated by the elearning advisory team, is aimed at creating a forum for collective learning. This thematic group was formed in November 2011 to facilitate communication, networking and support among faculty based elearning staff and our centrally based elearning team. Operating as a community of practice, this group identifies key elearning issues and concerns occurring across the university and shares ideas and resources to meet emerging needs. Meetings are held monthly and are organised to incorporate an open discussion as well as presentations by invited guests and group members. The presentations segment has covered topical issues such as 'Uploading of student assignments/presentations (file size issues)' and '*Blackboard* analytics.' Members can attend face-to-face meetings or join in via Elluminate *Live!* All meetings are recorded, with the minutes and recordings made available via the elReps blog available to Curtin staff (at: http://blogs.curtin.edu.au/elreps/elreps/). This initiative serves as a second tier professional learning opportunity, as the focus is on 'teacher-to-teacher' learning to strengthen support and networking through identification of common issues and information sharing to seek solutions. To date, this forum reaches 65 elearning staff located across the university, making it a powerful forum for information and resource sharing and generating good practice guidelines, and is proving to be a highly sustainable practice.

The communities of practice approach, outlined in the abovementioned examples, enhances our 'presence' and allows us to have strategic impact across the university through practices that are highly sustainable.

eScholars Program

A further substantial professional learning opportunity we offer is through the eScholars Program (for more information visit: http://ctl.curtin.edu.au/awards_grants/escholars/eScholars.cfm). As a strategic program supporting the university's flexible learning goals, individual projects implemented by staff, with support from the elearning advisory team, are aimed at promoting quality teaching and learning practices to positively impact the learning experience, student retention, and to support particular cohorts (e.g., first year, large classes, and culturally diverse groups). Aligned to these criteria individual projects also seek to address the technology trends identified earlier. The program is now in its third year, and consists of a $10 000 scholarship grant awarded to 10 successful eScholar individual or group applicants annually. The grant monies can be used for approved teaching buy out or resources associated with the particular project. The projects involve designing, implementing and evaluating elearning initiatives within particular teaching contexts. This strategy provides an enabling environment, which addresses the barrier of academics being time poor and or having insufficient resources to explore new educational technologies (Appelbee, McShane, Sheedy, & Ellis, 2005). The application process is deliberately simple to encourage academics to apply, and the selection process is competitive. Over the lifespan of the project, 95 applications were received, and 20 projects were implemented during 2010 and 2011 and a further 10 are underway. Fourteen projects are reported on in an e-book published in 2012, http://tinyurl.com/escholar2012 with the remaining projects to be included in a later publication. Figure 3 provides a visual summary of the projects, in terms of the primary learning technology integrated. Most projects were strengthened by their integration of multiple technologies to support achievement of student learning outcomes, including the integration of opportunities to build digital literacies and work readiness skills.

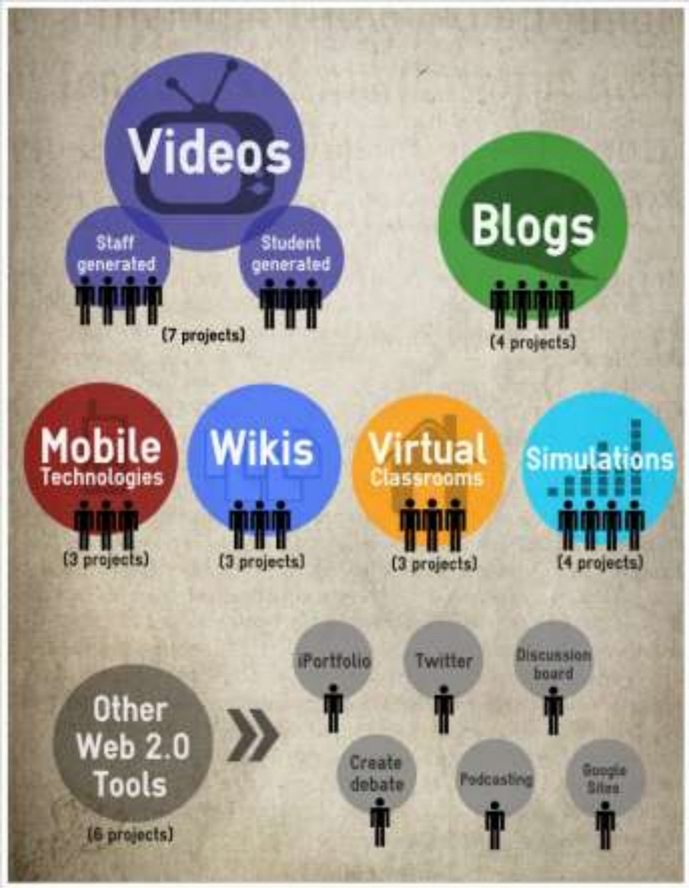

Figure 3: eScholar Projects categorised by learning technology (n=30)

The eScholars program drives professional learning through an integrated approach. It stimulates and gives impetus to improving teaching and learning through an award scheme; it promotes professional learning through action learning (analysing and mapping needs, aligning teaching practice with the university's strategic goals); curriculum development (i.e. designing learning activities, selecting appropriate learning technologies, implementing new elearning pedagogies, and evaluating and reporting the outcomes), and fosters research led teaching. At a more strategic (organisational) level, the eScholars program promotes awareness amongst staff and innovation with educational technologies. Experiences are shared among peers within the university and beyond through video case studies, conference presentations and an eScholar publication. These outputs are reusable resources that are used to showcase innovative teaching with technology at Curtin, and above all, the project makes significant impacts on teaching developments and technology integrated learning.

Discussion

The professional development literature purports that teaching and learning are complex processes that require comprehensive approaches that reach beyond short term, episodic skills training. Traditional one-off workshops of short duration, unconnected to the specific needs of individual teachers and their students and other professional learning activities are viewed as having limited impact on practice.

Therefore, our approach integrates multiple strategies that have been supported in previous research. The diversity in the range of strategies used reflects the different drivers including trends in elearning, the institutional culture and conditions, and responses to local pressures to support staff, similar to issues identified by Applebee et al. (2005). Our approach is aligned with several of the characteristics of professional development identified by Doecke, Parr and North (2008) and Mayer and Lloyd (2011) whose work focused on effective professional learning approaches for school teachers, but their findings are sufficiently broad to have relevance to higher education environments also. These features include collaborative engagement, experiences being anchored in specific contexts and contextually focused, sustained inquiry, and evidence based practice. Our focus on the practice of multiple forms of professional development, namely formalised activities (e.g., workshops, seminars); informal activities (e. g., discussion groups); immersion and problem solving; curriculum development, action research; coaching and mentoring, and professional networks and communities of practice, is also sanctioned by previous work in the schools sector (e. g., Day, 1999; Knapp, 2003; Meiers & Ingvarson, 2005), and sufficiently address the need for multiple approaches and strategies within higher education settings. In its focus on context, our work is aimed at enabling staff to bring about positive student learning impacts. We do this by providing external expertise to local environments, challenging problematic discourses, creating opportunities for professionals to interact within communities, and ensuring our content is aligned with strategic goals, which are further strategies endorsed by Doecke, et al. With regard to the content of professional learning, our work ensures the integration of knowledge in three areas – pedagogy, students, and technologies, aligning it with Timperley, Wilson, Barrar, and Fung's (2007) research that focused on the first two areas, and Applebee et al.'s (2005) work which addressed the third area. The quality indicators that guide our work include alignment with strategic university goals; being embedded within teaching; being diverse in form; being appropriate to both individual and group needs; promoting collaborative engagement; inducting early career teachers and those new to elearning; and demonstrating accountability through evaluation of practice, most of which derive support from both Doecke et al. and Applebee et al. Similarly, McNaught, Phillips, Rossitter, and Winn's (2000) study provided a helpful framework to reflect on and guide the analysis of our professional development approach, particularly its focus on staff issues and attitudes, policy supporting / inhibiting diffusion and uptake, institutional resources, customisation and examples of good practice. We believe the combined elements provide us opportunities to leverage staff engagement to bring about changes in thinking, knowledge, skills and practice.

Whilst our current initiatives reflect good practice principles in professional development with regard to approach, strategies, contexts, content, and quality indicators, it is not without a few challenges. For instance, although we consider the overall participation rate in workshops to be satisfactory, it raises concerns that a large proportion of staff still prefer this traditional form of professional development, which has recognised limitation in terms of transferring and embedding the skills into one's practice. A further challenge is that it is not a requirement for teaching staff to participate in elearning professional development, yet all staff teach online (to varying degrees), and for many this is a new environment requiring different pedagogies. Associated with this challenge is the notion of staff motivation to participate in available elearning professional development opportunities. Currently this appears to be driven by need and the desire to gain new or additional skills among some, in the absence of a reward and recognition scheme. The latter could significantly increase participation rates contributing to widespread and perhaps a more even spread of elearning developments. A final challenge we face is the absence of follow-up on professional development activities, other than the eScholars program, to gain a better sense of strategic impacts on teaching and learning enhancements. We are exploring how these challenges might be addressed as we move forward.

Having analysed our current initiatives and situated our work within the professional development literature, we are able to extract a set of design principles for sustainable professional development focused on technology integrated teaching and learning within our higher education environment. These six principles articulate some of the ideas proposed by Hawley and Valli (1999) and Wells (2007), and reflects our evolving conditions and practices.

To be sustainable our professional development approach must:

1. Be aligned with the university's strategic teaching and learning goals, technology trends and infrastructure;
2. Give staff timely access to professional development opportunities that are integrated into a coherent system of recognition and reward;
3. Afford continuous and ongoing conditions, resources and opportunities for innovation and scholarly activity with integrated support and follow-up mechanisms;
4. Embed participant experience in active engagement with educational technologies;
5. Implement multiple approaches and strategies that are responsive to situational complexity and educational change to support knowledge building and sharing across institutional structures.
6. Integrate accountability measures demonstrated through evaluation metrics and quality indicators such as teaching innovation, learning enhancements, leadership, scholarship and sustainability of practice.

Conclusions

In this paper we described and analysed our approach to professional development by reflecting on the traditional and non-traditional strategies we adopt to respond to rapidly evolving educational technology trends. We have drawn on evidence-based practice to construct a set of design principles to guide future iterations of our approach to professional development. Underpinning these design principles is the understanding that technology innovation is both technical and social, therefore professional development should be built around purpose and simultaneously embedded across all layers of the organisation. From this, we conclude that it is necessary to adopt multiple, relevant and sustainable professional development strategies to respond to issues within a rapidly evolving higher educational climate. Our analyses have identified several challenges and raised the following implications to shape our future practice.

Firstly, our design of professional development has evolved from the traditional approach of one-off workshops to a complex and diverse range of activities. Success of this new approach requires positive leadership, strategic direction and the conditions to make advancements in elearning a core activity within the university.

Secondly, leading in a climate of change demands specific and complementary skills and attributes within the elearning advisory team, which facilitates 'stepping up' as agents of change who simultaneously promote innovation through 'lighthouse' projects, develop capacity among staff and embed quality practices in elearning across the university.

Thirdly, all of our initiatives must foster a culture of digital literacy by influencing how staff 'think' about and 'do' teaching and learning, rather than limit our focus to the tools used. This requires stronger shifts towards technology integration to realise new forms of scholarly collaboration and engagement. This shift has already begun to occur in most of our work, but can benefit from continued development in this direction.

Implementation of our guiding principles and mindfulness of the above mentioned implications provides us with direction to shape the next iteration of our approach to professional development.

The changing role of learned bodies and membership organisations: some UK experiences

Maren Deepwell
Association for Learning Technology (ALT)

John Slater
Association for Learning Technology (ALT)

With the extensive changes to funding and employment security now underway worldwide, membership bodies and learned and professional associations are finding that their role is changing so as better to represent their members' views and respond to their needs. In the United Kingdom (UK), members show increasing interest in acquiring and retaining professional standing. As government selective funding decreases, activities are being displaced from the centre to within the community with the membership body taking an increased organisational and broker role. A new governmental focus on accountability and impact is changing members' priorities leading to revised activities by learned bodies. This paper discusses the changes necessary for professional bodies to continue to lead in the changing climate.

Keywords: funding, accreditation, ALT, professional bodies, impact, membership organisations.

Background

The Association for Learning Technology (ALT) is the UK's membership organisation in learning technology. It aims to ensure that use of learning technology is effective and efficient, informed by research and practice, and grounded in an understanding of the underlying technologies, their capabilities and the situations into which they are placed. It does this by improving practice, promoting research, and influencing policy (ALT, 2011). It is cross sectoral from schools to higher education and also attracts members from industry and government.

In the UK much central government expenditure has supported learning technology across higher and further education for a number of years (see (JISC, 2012) and links therefrom). Activities funded have involved: pure research; seedcorn activities; commissioned surveys; pilots of technologies, techniques and approaches; initiatives where significant sums (in three cases tens of millions of US$) are spent within institutions through bidding processes; and a full scale (and unsuccessful) online university (HEPI, 2005) costing over $100M.

Activities have also varied according to technology, pedagogy, degree of learner focus and style of government intervention. More technological examples include a Centre of Excellence for Reusable Learning Objects at London Metropolitan University (RLO-CETL, 2009) funded by the English Funding Council, work on Flexible Service Delivery and shared services (JISC advance, 2012) funded by the Joint Information Systems Committee (JISC) and work in developing European and other standards for exchanging learner information (Dempsey, 2010) also part funded by the JISC. Less technological are Higher Education Academy (HEA) and JISC work on Digital Literacies (JISC, 2011) and work on learner experiences (JISC, 2009).

All this has led to a considerable growth in the learning technology community and in its activities as institutions have evolved structures (research and practice), in part to respond to government funding opportunities. ALT members have been major recipients of funding with ALT occasionally acting as a communication channel with funders or as a broker bringing together groups of bidders.

With the contraction of the central funding base over the past 3 years, both individuals and units have tended to refocus on more institutional matters. More higher education money will now "follow the student" with English tuition fees increasing by a factor of about 3. A corollary is less money from central funders. JISC in particular has had a major review (HEFCE, 2010) by its main contributors leading to clear decisions that "Research and Development activity should focus on horizon-scanning and thought leadership" and that "services and projects should be rationalised with a view to significantly reducing their number".

Contraction is painful for central funding bodies which have previously provided control and support for their funded work. Funders have now instituted charges for events and services that had been free. They are also archiving significant quantities of completed work (JISCmail, 2009). Initiatives that remain such as the current Digital Literacies Programme are less fully funded and involve community bodies as participants, as brokers and as disseminators. There is thus a growing need for self help and mutual support in the community, including in staff development. ALT's role is developing to provide efficient mechanisms for this to happen.

Institutional emphasis

Government and central funders have changing policy language from that of having their own policy objectives and priorities, reflecting their own beliefs and the advice of expert consultants, to that of helping institutions and individuals to meet their own objectives. The current JISC strategy (JISC 2010) has five strategic objectives of which three begin with "Help institutions to" and the other three stress value for money and cost effectiveness. More money is given directly to institutions and less retained in the centre. This results in changes in whence learning technology researchers and units within institutions seek funds - away from a concentration on specific outside funders towards more support within the institution for activities more closely aligned to the institutions stated objectives, and to diversifying appeals to external sources, including international and European ones.

This leads to a growing role for the professional association as a facilitator and broker. This is evidenced by the facts that the number of Special Interest Groups in ALT has trebled within a short period, demand for free development webinars has escalated, events providing advice on how to bid more widely have been repeatedly oversubscribed, and the wish to work as a community facilitated by the membership body, always present in the learning technology community, has taken a higher profile with increased electronic activity in diverse channels.

Institutions in the UK are subject to other pressures as a result of changes underway. One is responding to the needs of learners. For this and other reasons, as elsewhere, many now articulate the provision of learning supported by technology as a clear part of future offerings (Purcell, Beer, Southern & Chipperfield, 2011). Most include some reference to it in institutional strategy documents. Some articulate that the way to achieve this is to do away with specialised units and expect every teacher and learner to "just do it". Others expect units to remain involved but with a more delivery oriented and support focus. Yet others expect central pedagogic and technology leadership. All anticipate a lot of staff development and seek options for its provision.

Such pressures are neither unique to learning technologists within education nor to education as a whole. They are certainly not unique to the UK. Major changes in job security, expected role, funding sources and the perceived need to take control of one's own development occur more widely, including in Australasia.

The changing financial model for professional bodies

Learned bodies need to remain solvent. Traditionally there was a simple activity and financial model outside certain "license to practice" disciplines such as medicine or engineering where the audience is captive and so fees are high. The traditional sources of income are membership (individual and organisational), events, publications, and occasionally grants. For ALT (and others) the largest contributor to central running costs has been an annual conference. With most funding bodies using their own staff for community activities, direct awards to ALT were small and usually restricted to those areas where ALT could act as a broker/aggregator. An example of this was the wiki on "What research has to say for practice" (ALT, 2010) where leading researchers were financed to produce guides and ALT took funding from three sponsors and distributed to the researchers.

More recently attitudes have changed, with the help of a not inconsiderable push from a government which is more widely seeking charitable bodies to take over the provision of services to save money (Cabinet Office, 2012). Thus for ALT the number of funded dissemination and brokerage activities has increased (from perhaps 1 a year in the period 2006-2009 to 4+ a year in 2010-2012). The new roles include putting together a reviewing structure for products produced under initiatives, organising user involvement in trials of service sharing projects, organising the production of a MOOC, and taking a significant role in dissemination. This last partly results from the realisation by funders that, by consistently relying on their own support and dissemination mechanisms, they may largely be disseminating to their own perhaps small and closed "supporters club".

ALT represents a wider community, solidly based within institutions and "is its members". This has been brought about by a culture of openness and community building. As a result, overall income has held up despite rapidly moving to an open access journal, changing the membership structure and remodelling the conference and other events to be more online as attendance budgets are threatened. ALT has also been gifted money.

Increasingly ALT has been contacted by funders and national bodies who are anxious to be seen to be consulting the communities for which it is a, hopefully faithful, proxy. Previously, ALT views were interposed opportunistically. This has led to some nominating rights to national bodies which in turn leads to more interest in membership and a virtuous circle.

Increased emphasis on professionalism and membership

As job security diminishes, individuals are keener to be seen as professionals who keep up to date with practice, and have their professionalism recognised. One way of doing that is to engage with a professional and learned body. Another is to sign up within that to a professional development scheme within that body. Even though Learning Technology is not a "license to practice discipline", it is nevertheless one in which a need for continuous updating is recognised. The Certified Membership of the Association for Learning Technology Scheme CMALT (ALT 2012) recognises this and provides peer-based professional recognition embracing the all practice in the context of Learning Technology. It is widely applicable and is not specifically UK oriented.

CMALT is a portfolio-based professional accreditation scheme developed by ALT to enable people whose work involves learning technology not only to have their experience and capabilities certified by peers but also to demonstrate that they are taking a committed and serious approach to their professional development. It has developed into a community drawn from across educational and commercial sectors, committed to professional and personal development. Participation in the scheme has steadily increased over the past years, with many members achieving accreditation and continuing their involvement with the scheme as assessors (See Table 1).

Table 1: ALT Membership numbers.

Year	**2006/7**	**2007/8**	**2008/9**	**2009/10**	**2010/11**	**2011/2**
All Individual Members	496	433	474	661	926	1195
Those Involved in CMALT	18	18	56	165	332	422

The upward trends have continued into 2012/3. While some of the overall membership is undoubtedly to do with identifying a better set of membership benefits and taking on new and less expensive classes of member, the overall membership increase is considerable. Churn in individual membership has decreased since the early noughties. A new research strand in CMALT is under design after an initial primarily practitioner focus.

A further CMALT driver has been a UK move for institutions to provide comparable Key Information Sets (KIS) for potential students and the public, following a US model and some previous attempts such as the Teaching Quality Information and UNISTATS (for the current version see (UK Government, 2012)). Statistical information on the professional standing of all those involved in teaching and supporting learners is required in many accreditation processes and may be added to the KIS.

A further major shift is in recognising the role and importance of learners in quality processes. The introduction of the National Student Survey in 2005, (Richardson, Slater & Wilson, 2007), modelled in part on Australian instruments, has led to changed behaviour by institutions, for instance in the area of assessment and feedback which was perceived as weak in many institutions (Williams, Kane, Satya & Smith, 2008). There is increased enthusiasm for obtaining the considered views of learners. However, data still suggests that many students can be single minded in seeking to maximise face to face one on one contact with lecturers (Shift Learning, 2012). ALT is working with the National Union of Students (NUS) on attitudes, surveys and codes of practice and regularly has NUS officials on its committees and as invited speakers at its events. While student politics can sometimes be treacherous to navigate, we have successfully worked jointly on several activities. Having such relationships is especially desirable at a time when learner control is seen as increasingly important.

Conclusion

In times of austerity with contraction of the opportunities from central government, the role of the professional membership body has changed and increased. This is happening across the developed world. Bodies need to represent their members with government, institutions and funders, support them fully in their drive for professionalism, and take over evaluation and dissemination activities from government in a more cost effective fashion. They need to act as aggregators and as brokers between policy makers, learners, practitioners and researchers. Sustainability follows if a body leads appropriately for its community of members and remains respected as representing them. It is possible to do this successfully.

Towards a sustainable support strategy for online students

Elizabeth Smith
School of Natural and Built Environs, Civil Engineering
University of South Australia

Anne Lonie
Division of Information, Technology, Engineering and the Environment
University of South Australia

Helping first year students develop the sociological competencies required of 21st century engineers, such as professional reflection, effective teamwork and cross-cultural sensitivity, remains a challenge, particularly for external students. This paper reports on the experience of conducting an online engineering practice course, which focusses on these competencies, for external students and on the strategies adopted to support and encourage student participation. Some of the strategies and practices which were implemented were successful in the short term, but many will not be sustainable. However, it is hoped that the lessons learnt from this development will improve future offerings of the course and generally enhance the way we support online students.

Keywords: supporting online learning, Group work

Introduction

In 2012, The University of South Australia offered full time external students the opportunity to complete a professional practice course *Sustainable Engineering Practice*. This course introduces students to the engineering profession and how it is practised within a ‘sustainable’ context. They learn about their possible future roles, the current engineering work environment, professional attributes of engineers, engineering ethics and sustainability. The embedding of these concepts into the course learning outcomes at an early stage is important, because it introduces students to the notions and processes required to manage their future careers. The course also aims to develop core professional skills and personal attributes, such as sourcing and using information, critical analysis and reflective practice, effective teamwork, cross-cultural sensitivity, engineering report writing, and effective presentations. The teaching and learning strategies are centred on team and collaborative project work, consultation with cultural and professional advisers and problem based learning, as students work on real engineering problems in Australian and international contexts.

Helping first year engineering students develop such skills presents difficulties and challenges, since cohorts are diverse and many students enter their degree program with a narrow view of engineering and poor communication skills (Kelly, Smith & Ford, 2012). However, the challenges become even more pronounced when presenting courses which develop these skills in off-campus students and, due to the practical difficulties involved, this is an area which is largely neglected in online engineering courses and subjects (McIntosh & Weaver, 2008). Online learners may also feel a sense of isolation that can lead to lack of engagement and an unsuccessful learning environment for them, but this can be minimised if a sense of community exists in the online course and productive social interaction can occur (McInnerney & Roberts 2004). A feeling of belonging, enjoyment and interest in the tasks will all help with engagement in online courses (Libbey 2004, Furlong 2003 & Kahu 2011)

Assessment strategies

Student achievement of the *Sustainable Engineering Practice (SEP)* course learning outcomes is measured by three assessment tasks, as shown in Table 1. The first task involves the submission of an individual report and forum discussion contributions which focus on the role of the engineer within local communities and the importance of communication and cross-cultural sensitivity within engineering projects. Students must define their ideas of culture and communication, present their own perspectives, and reflect on the perspectives of others.

The second task requires students to work progressively on a learning journal, and to begin their own professional development plan for the skills, attributes and knowledge they will need to develop before entering the profession.

The final assessment task is an authentic project based learning task in which students work in teams to develop a sustainable engineering solution to an Engineers Without Borders problem (EWB, 2012). The design projects are based in locations and subject areas which are unfamiliar to the students, and for which the design solutions require considerable research, creativity, teamwork and communication.

Each assessment as described above is thoroughly scaffolded, with detailed instructions and support resources. Within this type of supportive environment, the progressive development of student skills has been mostly successful for on-campus students; however, as can be seen from the discussion below, replicating this success within a purely online environment has been difficult.

Table 1: 2012 Assessment breakdown for [Course Name]

Assessment Task	Description
Individual Report 15%	1000-1500 word report on the role of the engineer and importance of cross-cultural awareness and communication in team work.
Development Portfolio 35%	• Engage with the lecture videos and set readings to complete a series of quizzes; • To work progressively on a learning journal submitting at least 5 entries; • To reflect on their own professional development by producing a resume and preparing a development plan for the skills, attributes and knowledge they will need to develop before entering the profession.
Engineers Without Borders Group Project 50%	Work in groups of 4 to 6 to complete a project report and presentation.

Student Engagement

At commencement of teaching, 39 students were enrolled in the course. By Week 6, 29 students were still enrolled. By the final week (week 13), this had dropped to 24 students. Unfortunately, only 6 out of the 24 students passed the course. This was despite extensive measures put into place by the teaching staff to contact, encourage, engage and support students to help create a sense of community and an opportunity for students to develop a sense of online self. Some of those measures included:

- Extensions of assignment deadlines with no penalty
- Provision of formative feedback for all assignments, to improve final submissions
- Email, personal messaging and personal telephone contact with the students
- Adjusting of submission methods and group reassignment
- Reduction of minimum group numbers, to make collaboration easier
- Staff assistance and support with group work, including management of collaboration tools
- Posting of continuous reminders and warnings about module work, assignment work and deadlines.
- Provision of live online helpdesk sessions via Adobe Connect virtual classrooms.
- Monitoring of forums and personal journals and messages of those students who have not participated, encouraging them to involve in activities.
- Monitoring of group work online tools.
- Simplification of some tasks to encourage motivation.

However, despite this support and encouragement, the majority of students did not engage with the course. The numbers of students who were motivated to study and were submitting work progressively declined over time. Through casual conversations with other external course teaching staff, teaching staff realised that a 30% success rate is common in fully external courses. While teaching staff were able to implement these support measures for the relatively low numbers in this course, this level of personal interaction would obviously be unsustainable for large classes.

Methods used to support student engagement and development of reflective practice, cross cultural sensitivity and teamwork activities are discussed in more detail below.

Reflective Practice

Students are required to submit an online learning journal containing at least five entries. Careful design and support of reflective writing is essential, so each entry is supported by scaffolded templates, including open-ended sentences for those who needed them. Students are introduced to the process of reflection and the reflective writing style via videoed lecture presentations, resources on reflection processes, and examples of good practice. Because the reflective writing style may be new for many students, early formative feedback and on-going regular feedback are crucial to increase their confidence in this writing style. Consequently, the marking is labour intensive, requiring confident, competent, empathetic markers with high level personal and professional skills (Kelly, Smith & Ford, 2012).

In the online course, teaching staff provided formative feedback for early journal submissions, and summative feedback for later submissions. Because the journal entries reflect on the students' progress and engagement with the course, they gave very early valuable feedback on the course, which teaching staff would not otherwise have received. From this feedback, the staff made early adjustments, such as modifying the online learning environment to make it easier for students to find information.

Despite intensive support and feedback from teaching staff, the online students found the progressive nature of the journal to be demanding, and many had ceased to participate in the course by the time the professional development submissions were due. The journals were an excellent way of keeping connected with the students, but they did not always provide evidence of lacking motivation or struggles with the course. The number of journal entries submitted dropped from 19 out of 24 for the first entry, down to 12 for the second, 7 for the third, 6 for the fourth and 5 for the final reflection.

Cross-Cultural Sensitivity

Engineers are required to work in multidisciplinary and multicultural teams and for a wide range of diverse clients. Consequently, a good understanding of diversity and cross-cultural awareness is important. The course integrates diversity and culture through activities which focus on the meaning and definition of culture, and the key considerations for engineers working with culturally diverse groups. Indigenous advisors and the students share perspectives on culture, and students use the learning from these sharing activities to inform their individual report assignment.

This assessment has been reasonably successful in the online course for several reasons. Course staff, advisers and developers were able to develop learning activities such as guided and moderated online discussion boards, which promoted frank and thoughtful discussion of sensitive issues such as cultural awareness. Secondly, the assessment tasks were produced as individual work, with resources provided by staff, which gave online students more flexibility and support in their research and writing. However, the intense nature of the student/teacher interaction would be difficult to sustain if this part of the program were not already supported by the Indigenous Content and Service Learning Advisors.

Supporting Teamwork

Embedding teamwork skills in an online environment is very difficult when students are scattered around the country and possibly worldwide. Six groups were allocated by staff, based on geographic location (in the hope that geographical proximity would enable group face to face meetings). To support the early stages of teamwork the following strategies were used:

- Students introduced themselves via an introductory forum where 18 out of 24 students responded
- Students then contributed to an 'ice breaker' wiki, for which 6 out of 24 students responded
- Early virtual helpdesk sessions were scheduled where students could meet teaching staff and other students, (only 4 students participated in the first three weeks of these sessions).
- Students completed a Belbin inventory, which is a personality trait test assessing team functionality. This proved popular and encouraged self-awareness, with many students discussing their results in their learning journal. Where 16 out of 24 students participated.

Out of the six groups that were established only one completed the project as a group. The other groups collapsed due to lack of participation amongst members. Consequently, several students worked on the project by themselves and only two of these completed enough work to pass the course.

Teaching staff have examined the factors which promoted the functioning of the one successful group, with the aim of replicating these factors for future groups. Several critical factors were identified. For example, this group made regular use of real time online collaboration tools (particularly the virtual classroom) to meet and discuss the project, and to prepare the report and presentation. The group also made regular use of asynchronous collaboration tools (such as group forums) to discuss project progress and allocation of tasks. However, use of the tools alone does not explain the variation in effectiveness. After all, these tools were available to all groups, were marketed to all groups, and training was offered to all groups, but they were only used effectively by one group. The most significant success factor appeared to be that this group had an obvious leader, who motivated the members to keep on track with the project.

Steps to improve student engagement

The teaching and development staff have identified several ways in which they hope to improve the retention and engagement rates in this course. The first is by redeveloping some of the assessment and learning activities, while maintaining the integrity of the course learning outcomes. The content of the group project (although not the tasks) will be simplified, so that students can focus more on developing their teamwork, their report writing, sourcing information, reflective practice and referencing skills, rather than devoting all their efforts on providing engineering solutions. Future group report submissions will be produced using wiki and ePortfolio tools, to enable easier collaboration. Teaching and program staff are also considering an assessment model in which students have the choice of submitting work progressively through the study period, thus getting early feedback on their progress, or electing to submit all assessment items at the end of the study period, which gives them more flexibility in their study pattern. Other, more individually focused courses will be recommended as pre-requisites for this course, allowing students to become familiar with the online environment and tools before having to use these online tools for teamwork and group collaboration. Students will also be allocated to groups later in the course, once enrolments have settled and student participation is confirmed.

The second issue, which we need to approach, is that of sustainable teaching staff interaction and support. We have discussed the various extra-ordinary measures which were taken during this course to initiate contact with students, manage their study, guide their time management, support their group work, etc. These measures were possible given the small numbers of participating students, but would be difficult to sustain with large cohorts. Some possible strategies include the expansion of current tutor training to include training in producing efficient and effective formative feedback which is supportive and timely for students, and quick and easy for staff (greater use can also be made of electronic feedback tools). The online environment will be restructured to highlight collaborative tools such as forums and virtual classrooms, in the hope that this will better market them to students. Support websites will also be emphasised, to give students additional practice and training in using these collaborative tools.

Conclusion

Student retention and engagement has proven to be difficult in an online engineering course which focusses on development of professional skills and teamwork, despite an intense level of teacher support and management. However, these are essential skills for future engineers. A number of strategies have been implemented to encourage student participation and enable the development of these skills in an online environment. It is hoped that future iterations of this course will be able to intensify and sustain these strategies and offer adequate support to online students. This will be especially necessary as class sizes increase.

Exploring and applying the 3E Framework for technology-enhanced learning

Keith Smyth
Office of the Vice Principal (Academic)
Edinburgh Napier University

Dr Keith Smyth is a Senior Teaching Fellow and Senior Lecturer in Higher Education, and Programme Leader for Edinburgh Napier's online MSc Blended and Online Education. His research interests in technology-enhanced learning are in the areas of curriculum design, staff development, institutional strategy and the student experience. Recently he has been leading Edinburgh Napier's development of their 3E Framework for technology-enhanced learning, which has begun to be adapted and re-used in various ways since it was made available as an open educational resource in late 2011.

Panos Vlachopoulos
Centre for Learning Innovation and Professional Practice
Aston University

Dr Panos Vlachopoulos is the Programme Director of the Post-graduate Certificate in Professional Practice in Higher Education. He has international experience of working with academic staff in areas of learning design with new and emerging technologies. His research interests include online and blended learning design, online tutoting, reflective practice and student-directed learning. He holds a PhD in Online tutoring from the university of Aberdeen, a Master of Education in Educational Technologies from the University of Manchester and a first degree in Philosophy and Pedagogy from Aristotle University in Thessaloniki Greece.

Intended audience and degree of expertise/past experience required

Lecturers, Staff Developers, Learning Technologists, Heads of Department, and other participants who have an active role in using or promoting technology-enhanced learning, or who lead institutional strategy in this area.

Statement of objectives for the workshop

The overall aim of this workshop is to engage participants in exploring a framework for good practice in technology-enhanced learning that is based on principles of active engagement, learner autonomy, and students as co-creators of learning resources and experiences, and which has successfully been used and adapted within a range of Higher Education and Further Education institutions within and also beyond the UK.

The key objectives for this interactive workshop are for participants to:

1. Identify a range of key ways in which technology-enhanced learning can help meet learner needs, common teaching challenges, and institutional challenges in Higher Education

2. Discuss how Higher Education institutions have tended to approach introducing minimum benchmarks and quality guidance for the use of technology in learning, teaching and assessment

3. Explore the rationale and design of the 3E (Enhance, Extend, and Empower) Framework for embedding the active use of technology in learning, teaching and assessment, and the range of ways in which it has been adapted to support good practice within and beyond the UK

4. Consider how the 3E Framework as a Creative Commons open educational resource (OER) could be adapted to their own teaching practice, programme design, and institutional strategies in TEL

Detailed description

For a number of years a 'minimum' online presence for all modules was an institutional target at Edinburgh Napier University, as it has been within many other Higher Education institutions. However in response to staff and student feedback from an evaluation of technology-enhanced learning (TEL) in 2009, and our increasing institutional knowledge and experience in TEL, a new benchmark for the use of technology was approved by the

University. This proposes that all modules make an *active* use technology to enhance key aspects of the learning, teaching and assessment (LTA) experience, and to engage students with their subject,

The 3E Framework, based on an *Enhance-Extend-Empower* continuum of TEL that in an earlier form had been successfully implemented in a cross-institutional e-learning transformation project funded by the Scottish Funding Council, was developed as the basis for the benchmark and a means for staff to consider aspects of their modules that could meaningfully adopt technology to benefit the LTA experience.

The 3E Framework (Smyth et al, 2011) provides guidance with examples across a range of LTA activities that show how technology might be incorporated at a minimum level to increase active learning (Enhance), through to further developed uses of technology that underpin more sophisticated, higher level learning that reflect how knowledge is created, shared and applied in professional contexts (Extend and Empower).

This session explores the ethos and design of the 3E Framework, including illustrative and real examples which demonstrate how technology can be used across a range of LTA activities and disciplines at each of the 3E stages. Session activities will allow participants to engage with the Framework from strategic, educator and staff developer standpoints, and explore how the 3E Framework as a Creative Commons open educational resource (OER) has been used for a range of purposes, in a range of contexts, across several institutions. This will include applications of the 3E Framework in course design, teaching, staff development, evaluation, and quality enhancement projects and initiatives in the UK, New Zealand, and Greece.

Participants will also be supported in exploring how the 3E Framework, or key aspects of it, could be used to inform TEL practice within their own professional practice and institutions.

This session will be highly participative, and involve interactive exploration of online resources, individual activity, and group and open floor discussion as follows:

Part 1: Introduction to session including discussion of TEL in today's Higher Education context

Part 2: What does TEL mean in your institution? (Open floor discussion of approaches taken, experiences in implementation, and institutional guidelines and expectations)

Part 3: Introducing the 3E Framework. Interactive exploration of the 3E Framework including how the Framework is being used at Edinburgh Napier University to underpin the transition to an increasingly active use of institutional and other technologies to engage and support students

Part 4: Short break

Part 5: Exploring the 3E Framework in different institutional and cultural contexts. Facilitated activity exploring and drawing lessons learned from the application of the 3E Framework within a range of different contexts and institutions, with participants working in small groups to identify aspects of the approaches explored that they feel could be usefully adapted.

Part 6: Applying the 3E Framework. Individual activity in which Participants with primarily teaching interests are asked to map their teaching to the 3E Framework in terms of their current or planned use of technology. Participants with primarily strategic or staff development interests are asked to explore the illustrative and real examples in the 3E Framework, and consider how these may map to strategic aims or could be used in supporting staff development provision.

Part 7: Benefits and implications for institutions. Participants work in groups to consider the challenges that need to be addressed in adopting an active 'benchmark' for the use of technology within institutions. (Group discussion with open floor 'report back').

Part 8: Concluding evaluation of session.

Toward a framework for evaluating blended learning

Michael Smythe
Nelson Marlborough Institute of Technology

Blended learning for some is the future of education itself (Brown & Diaz, 2010). However blended learning lacks a coherent body of research that unequivocally demonstrates learning benefits over traditional modes of instruction. Yet there is a growing volume of evidence to support the view that blended learning can result in improvements in student learning outcomes and enhance student satisfaction (Dziuban, Hartman, Cavanagh & Moskal, 2011; Garrison & Vaughan, 2008; Graham, 2006; Sharpe, Benfield, Roberts & Francis, 2006; Vaughan, 2007). The means to evaluate its effectiveness is frequently lacking since there are a relatively limited range of tools and methods that support staff in designing blended learning curricula. This paper describes one component of a possible framework for evaluating blended learning – the use of a course design rubric. A new rubric is outlined that attempts to represent a range of good practice in blended learning design derived from the literature and evidence-based research.

Keywords: blended learning, quality evaluation, rubric.

Introduction

The use of blended learning has been targeted by many education institutions as a way to integrate pedagogy and technology with teaching and learning. It is also considered a method to provide a more flexible and sustainable educational model for educational institutions by reducing students' time and space commitment (Dziuban, Moskal & Hartman, 2005).

The 2011-2013 NMIT (Nelson Marlborough Institute of Technology) Investment Plan included a target of 50% of courses using a form of blended learning by 2013. One element that was identified to successfully implement this strategy at a programme and course level is the adoption of an effective method to evaluate the quality of blended learning. After completing an extensive literature review it was considered that a new, customised course design rubric was needed as part of a broader framework for the evaluation of blended courses.

Blended learning dimensions

Although there is little consensus around a definition of the term blended learning it has become widely accepted and is ubiquitous in all forms of education and training. Blended learning at its simplest is nothing more than employing a variety of media and methods, most often a mix of online and face-to-face learning. However this combination is subject to a range of permutations in technologies, pedagogies and contexts (Garrison & Vaughan, 2008; Graham, 2006). These permutations, or dimensions to blended learning, are found to be common within a number of tertiary educational institutions such as;

- **Modes of delivery** - The combination of traditional learning with web-based online approaches
- **Technolog**y - The combination of media and tools (technologies) employed
- **Pedagogy** - The combination of a number of pedagogic approaches irrespective of learning technology use
- **Chronology** - Synchronous and asynchronous approaches

(Oliver and Trigwell, 2005; Sharpe et al., 2006)

Evaluating quality in blended learning

The issue of quality in teaching and learning environments is a subjective and multifarious concept, dependent on a range of factors relating to students, the curriculum, faculty, technology and learning design (Meyer, 2002). Chickering and Ehrmann's (1996) seven principles of good teaching often forms a basis for the quality evaluation of many blended learning courses and their impact on students. The Sloan-Consortium quality framework (The Sloan Consortium, 2011) is another structure often used to evaluate online courses in particular, but is also used for blended environments and is built around the 'Five Pillars of learning' - effectiveness, faculty satisfaction, student satisfaction, access and cost effectiveness (Shelton, 2011).

Despite these efforts in defining and examining quality issues concerning online courses, a defining instrument to evaluate quality is one of the key challenges for blended learning since it incorporates both traditional and online instruction methods. Aspects not obvious to instructors or learners, such as instructional design, course development, and the use of technology are commonly ignored. In order to define the quality of a blended course, therefore, requires a comprehensive framework to identify these issues along with appropriate guidelines, as well as to devise an instrument and method for measuring the hidden aspects of quality.

Although there is no systematic, determining methodology to measure and ensure quality in blended courses, course design rubrics are capable of operating as an effective tool to support a quality framework. This framework needs to include a combination of quality assurance processes in addition to pedagogy-oriented approaches such as evaluation of course development and instructional design.

Using rubrics to evaluate quality in blended learning

What is a rubric?
Traditionally, a rubric is a scoring guide that sets out specific performance criteria. It defines precise requirements for meeting those criteria, and often assigns numerical scores to each level of performance. This provides evaluators with an effective, objective method for evaluating items that do not generally lend themselves to objective assessment methods. A rubric for online instruction can be designed to provide a common set of evaluation criteria for a diverse set of situations evaluating the readiness of an online course.

How are rubrics designed to be used?
A course design rubric is designed to be used as part of a comprehensive institutional e-Learning strategy. With a strategy in place, a well-designed evaluation rubric can be used as an instrument in blended and online course design as well as to provide guidance while developing courses. It can also act as a tool for periodic evaluation and improvement. This can be achieved by building in good-practice standards into a rubric which are well supported by the literature. Rubrics at the course-level are designed to be used in the following ways;

Table 1: Uses for evaluation rubrics

Use	Purpose
Self-evaluation tool	• To provide a framework for new courses • To inform reworking of an existing course
Institute-wide evaluation tool	• As a means to assist in the development of 'quality' online courses
Exemplars	• To identify best practices in online courses and recognise those that are creating quality courses

To be useful a rubric should not only be based on empirical-research but integrate a range of accepted pedagogical knowledge and principles. It should also able to be used in a variety of situations, within an array of review methodologies and operate as a free standing document to be used in both formal and informal contexts. Course design rubrics in general attempt to provide a frame to answer the question - *What does a quality blended course look like?*

Rubric origins

The most popular rubrics used in higher education for the quality evaluation of e-Learning are those developed by 'The Centre for Excellence in Learning and Teaching' (CELT) at California State University (2009) and the Quality Matters rubric (Maryland Online, Inc., 2009). Both of these are designed to be used as part of a systematic approach to online evaluation which includes peer review that use similar criteria and dimensions. Although there is relatively little research providing evidence as to the effectiveness of rubrics there is some empirical research supporting the use of the pedagogy nested within a number of these rubrics (Quality Matters, 2008). Most published rubrics include quality criteria that evaluate learning, learner support, course organization, assessment, design and the use of technology.

The New Zealand experience
The CELT rubric in particular forms the basis for most of the rubrics used currently in evaluating online courses in higher education including that used by a range of NZ-based institutes. For example, the NMIT Learning Design and Facilitation Rubric, the FLI rubric used by Lincoln University (FLI, Faculty of Commerce, Lincoln University, 2011), and the EIT rubric (Seitzinger, Jamieson, & Forlong-Ford, 2009) are all derived from the earlier CELT version.

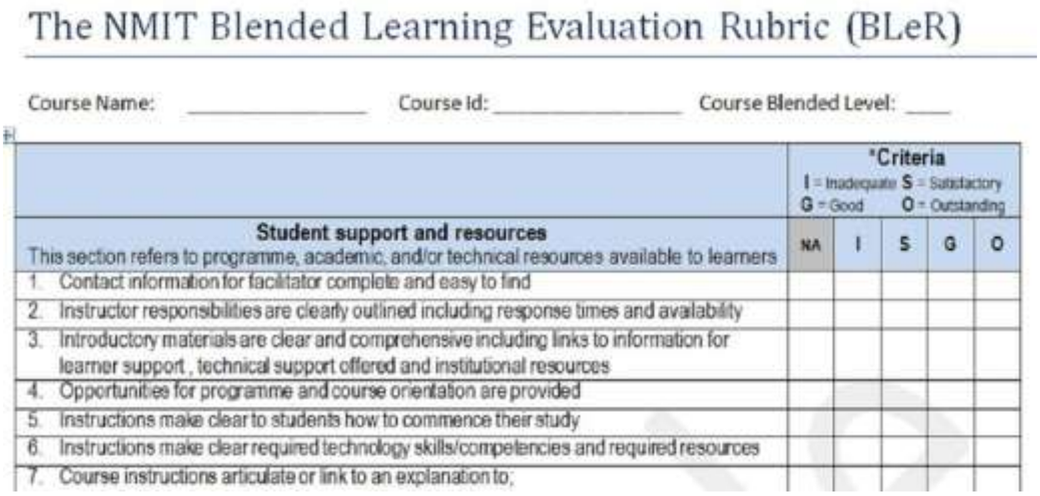
The principles outlined in the New Zealand e-Learning guidelines (NZ ELG, 2011) are aligned closely with the CELT rubric. These guidelines were developed partly to provide evidence-based effective practice guidelines and case studies. Since these reflect contemporary thought and empirical research they provide a sound basis for designing e-learning materials in a NZ setting and should be integrated into any proposed rubric.

A new blended learning rubric

This paper outlines a new Blended Learning evaluation rubric (BLeR) that is intended to assist in the design, redesign, and, or evaluation of blended and online courses. The rubric can be used in a range of contexts including as a tool to aid course creation and for self-evaluation of existing courses. It is also possible to obtain some measure of the quality of course facilitation and therefore aid in the creation of effective delivery methodologies. In summary, this new rubric aims to:

- Allow for a range of learning theories but embed a number of good practice principles
- Connect with any existing institutional flexible learning strategy
- Place learning design at the center of instruction
- Emphasize learning ahead of technology
- Be adaptable to support a range of individual and institutional needs
- Reference the New Zealand e-Learning guidelines (NZ ELG, 2011)
- Create a relative simple tool optimized for self-evaluation

It is intended that using a course development process which integrates the use of such a rubric should result in well designed courses that are organised, provide sufficient learner support, focus on the learners rather than content and are pedagogically sound.



The NMIT Blended Learning Evaluation Rubric (BLeR)

Course Name: ________________ Course Id: ________________ Course Blended Level: ____

	*Criteria I = Inadequate S = Satisfactory G = Good O = Outstanding				
Student support and resources This section refers to programme, academic, and/or technical resources available to learners	NA	I	S	G	O
1. Contact information for facilitator complete and easy to find					
2. Instructor responsibilities are clearly outlined including response times and availability					
3. Introductory materials are clear and comprehensive including links to information for learner support , technical support offered and institutional resources					
4. Opportunities for programme and course orientation are provided					
5. Instructions make clear to students how to commence their study					
6. Instructions make clear required technology skills/competencies and required resources					
7. Course instructions articulate or link to an explanation to;					

Figure 1: NMIT Blended Learning Rubric (BLeR) screen sample (Page 1 of 4)

Integrating blended learning within existing evaluation processes

Most blended learning evaluation rubrics take a process-orientated approach where a 'whole-of-course' view is used to assess learning design (but not to assess how well this design is being applied). Blended courses contain course-related documents and activities in e-format along with evidence of student engagement and participation. This affords the opportunity to assess the learning process over time rather than as a snapshot by the use of a rubric. In addition it may also be possible to evaluate a range of other factors such as the student experience and their relationship to the curriculum.

Blended delivery has two main teaching components - a classroom-based one and the online or 'e-bit'. The assessment of teaching practice in a classroom-based lesson is often subject to existing evaluative processes which can be complemented by an additional process such as a rubric, to evaluate the online part of the teaching and learning equation. Both processes can be reconciled by using the same or very similar criteria, while the facilitation aspect can be either evaluated as part of an amended teaching observation process or integrated within a rubric.

The use of the BLeR rubric in practice

To date, the BLeR has been tested across a limited range of diploma and degree level courses at NMIT during 2011 and 2012. A number of changes have been applied as a result.

- The rubric has been modified to include a more explicit scoring system after feedback from management and academic staff
- A more prescribed set of criteria to evaluate course facilitation have been added to broaden the range of uses for the BLeR
- A number of criteria have been simplified to lessen the need for evaluators to have extensive experience in online teaching and expertise in a range of theoretical areas

To date the rubric has encouraged the use of a team approach to course development and enabled a wider community of interest in blended learning to emerge.

Discussion

Blended learning offers the potential to completely rework the teaching and learning relationship thereby becoming part of a potentially transformative redesign process (Sharpe et al., 2006). The strategy of using the introduction of blended learning to rebuild courses, as opposed to just adding on technology to existing content, is becoming one of the defining characteristics of blended learning (Garrison and Vaughan, 2008; Littlejohn and Pegler, 2007; Sharpe et al., 2006).

It is apparent that to take advantage of this opportunity for redesign, blended learning needs to reference sound pedagogical approaches and practices that work together, to leverage educational technology and ensure the best conditions exist for learning. Technology itself is considered to be pedagogically neutral (Nichols, 2003). Consequently there needs to be an emphasis on pedagogy to prevent unsustainable technology-driven blended learning initiatives.

It is recommended that one of the foundations of a framework to achieve best practice in blended learning is the appropriate use of an evaluation rubric such as the BLeR. This provides the ability to underpin the transformative potential of truly sustainable blended learning.

From the preliminary use of the BLeR, it appears that such rubrics are capable of operating as an effective tool alongside a range of other initiatives to lead and encourage evolution in teaching and learning through the introduction of blended learning.

Looking forward

The key points to be derived from this study that could be relevant to policy and practice for tertiary institutes considering the adoption of blended learning are:

1. The role of pedagogy has a critical role to play in using blended learning as part of a transformative redesign process. One way this can be applied is through the use of a course design rubric that incorporates the use of pedagogy.
2. To build and maintain quality standards in a flexible learning environment an evaluation instrument needs to be part of an integrated course of action that includes attention to institutional capability, content development processes and most importantly, practitioner skills and knowledge.
3. Decisions regarding the use of evaluation tools and specific blended learning approaches within the curriculum design should be guided by a range of institutional documents such as blended protocols and good practice principles written into a wider policy.

The design and development of a suite of online professional development resources for academic staff: Framing the project

David Snell
Massey University

Jane Terrell
Massey University

Professional development for teaching staff at Massey University has been comprehensively remodelled in order to foster teachers as "future makers", exponents of models of teaching and learning that are suitable for effective 21st century knowledge creation and distribution. Given that the remodelling programme has strong support at significant levels of the university's leadership, it has a high chance of succeeding in its aims. This paper traces the initial stages of one project in the programme: the production of a suite of online resources featuring successful academic staff discussing aspects of their teaching. Loosely modelled on other online teaching development videos, the videos in the suite were envisaged to provide staff new to teaching, and those wishing to improve their teaching practices, with a readily accessible, practical explanation of how some of Massey University's leading practitioners operate. To help staff understanding at a deeper level, the suite included a series of brief information guides ('flyers') aimed at helping staff understand the theoretical terms underpinning the video discussions. This is an initial report on an on-going project.

Keywords: Teaching staff, professional development, videos, flyers, Massey University

Introduction

> The environment of further and higher education is changing in response to economic pressures, government policies and changing behaviours influenced by greater ownership of new technologies. In turn, this is encouraging institutions to review key aspects of their provision and to reassess what is delivered, to whom and in what ways (JISC 2011, 6).

Increased demands placed on tertiary teachers due in part to the increasing emphasis on the use of digital technologies, and in part to the shift in accompanying pedagogies, were factors that led to a recent reassessment of how professional development for teaching staff occurred at Massey University ("Massey"). The challenge for Massey, as with many universities, was to create a sustainable model of professional development that utilises the features of the digital educational environment in a way that is both inspiring and motivating to those participating. By combining face to face professional development with a suite of online digital resources, Massey hoped to inspire and motivate academic staff to transform their practice and re-conceptualise their learning designs in ways that are increasingly seen as critical to facilitating teaching and learning in the student-centred and technology-enriched learning spaces of the future (see for example Steel & Andrews, 2012).

The Massey University response

The challenge of providing a sustainable model of professional development that meets the on-going and evolving day-to-day needs of academic teaching staff led to shifts in both the underlying philosophy and the provision of staff professional development at Massey. The new model for the Massey Teaching and Learning Centre could be characterised as a shift from what Holt, Palmer and Challis (2011, p.6-7) label the "traditional paradigm" to what they describe as the "new emerging" paradigm, which positions such centres "at the heart" of teaching and learning within the institution rather than on the margins. The remodelling provoked a programme of change initiatives at all levels of the university, ranging from new policy documents to shifts in organisational structure and everyday practice. Significant initiatives at institutional level included:

- the development of policy documents that impacted directly on the expected provision and outcomes of staff development (*The Road to 2020, The Teaching and Learning Development Framework*)
- the establishment of College Directors of Teaching and Learning whose role included working closely with academic staff and staff developers to identify and provide appropriate and timely professional development

- the defining of a Massey University model of teaching and learning
- the restructuring of professional development services from a centralised to a ‘hub and spoke’ model, with regional centres established to meet immediate teaching and learning needs as and when they arise
- the integration of student learning services into core business of each regional centre. This change reflected the Massey philosophy that teaching and learning are in essence inseparable, and as such should focus on the needs of learners as well as those of teachers.

Such institutional change initiatives, with their positive impact on support for teaching staff, are evidence of the kind of distributive leadership that Steel and Andrews assert bodes well for successful change in teacher practice: “Changes in teacher practice require different levels of distributive leadership that can empower, enable and support teachers” (2012, 244).

In its policy document *Teaching and Learning Development Framework: Defining Directions for 2012-2015,* Massey established guidelines for how to “fully exploit opportunities provided by new digital media” and “provide enhanced professional development and lifelong learning opportunities for staff” (Massey University, 2012b, 6). The strategy further elucidated the university’s core principles of teaching development in terms of its effectiveness, range, scope, and capacity for provision that was both multi-faceted and grounded in meaningful contexts. Acknowledging staff as lifelong learners, the strategy was explicit about expected delivery modes and purpose. Based on “a philosophy of providing customised and flexibly delivered teaching development that can meet staff needs on request” the strategy was intended to “model and embed the use of educational technology in ways that promote a more collaborative, interactive, media rich and personalised learning experience for academic staff” (Massey University, 2012b, 6).

The underpinning philosophy that informed the restructuring of the Massey professional development model combined with explicit directives around delivery found in the Teaching and Learning Framework (2012b) saw the implementation of a new approach to delivering professional development for teaching staff. Customised workshops and one-on-one consultations concentrating on the pedagogy of educational technologies, blended delivery, and curriculum design and delivery replaced generic workshops around teaching practice. Not only were these new offerings tailored to the needs of new tutors and lecturers, they were also able to be utilised by experienced teaching staff looking for new ideas to reinvigorate their teaching. It meant that academic staff could access discipline-based workshops that supported their teaching, just-in-time, as and when required.

Similarly, recognising that learning to teach also occurs informally (Ling, 2009; Remmik, Karm, Haamer & Lepp, 2011), staff were encouraged to talk about issues and aspects of their practice with their colleagues through a range of interdisciplinary professional conversations facilitated by the Centres for Teaching and Learning. Academic staff were also urged to participate in peer mentoring activities with both academic colleagues and teaching consultants, where reflective practice was encouraged through the sharing of positive teaching experiences, and the exchange of advice and support for challenging and/or problematic teaching and learning situations. Such informal building of a network of peers valuing feedback and reflection is noted as an important underpinning element in sustainable change in teaching practice (Steel & Andrews, p. 254).

Complementing the face-to-face services, and in response to the requirement of the Teaching and Learning Framework to model and embed educational technologies, Massey’s National Centre for Teaching and Learning offered a suite of less formal, online modules that provided staff with the opportunity to engage with professional development materials. This three-pronged suite comprised:

- an introduction to the use of Massey’s Moodle-based learning management system
- a series of modules on the pedagogy and advanced operations of teaching online
- a series of staff development modules purchased from Epigeum concentrating on more generalist teaching practices and selected as appropriate for the Massey environment.

The project to produce a further suite of brief videos and accompanying flyers was thus the fourth prong of these online resources. Intended to enable academic staff to access the philosophies, ideas and experiences of their colleagues, the project provided a vehicle for selected skilled Massey teaching staff to share their practice both with their university colleagues, and with the wider educational sector via the Massey University website. Such resources could be utilised by educators as online simulations of professional teaching and learning conversations, and as stimulus and inspiration around specific areas of teaching and learning.

The development of a new resource

While the production of online videos and flyers to serve as a resource for professional development in teaching is far from an original idea, it has proven benefits. Providing teachers with new ideas and information, particularly around teaching pedagogies, in a readily accessible web-based format has proved to be a useful and successful teaching development tool worldwide (McIntyre, 2011). Although such a project requires careful planning, particularly in the pre-production stages, it was hoped that the bite-sized videos and flyers would be easily consumed as and when required, particularly by those McIntyre (2011, 10) describes as “time poor teachers feeling resentful and overburdened” by institutional demands on their time. Massey’s goal was to ensure that each resource would meet a specific pedagogical need, and highlight to staff that the content was not abstracted theory, but showcases of practices already happening in their institution, by colleagues they were working alongside. The resources were to be practical, concentrating on real world applications, and largely free of subject-specific references to enable easy transferral of skills between disciplines.

Planning for the videos began with the inclusion of two unique, unrelated projects in the 2012 National Centre for Teaching and Learning *Priority Initiatives Plan:* the “Spotlight on Teaching videos” project and the “In a Nutshell” flyers project. Both videos and flyers were intended to be displayed and downloaded from the Massey website. However, the obvious synergies between the projects led project leaders to quickly agree that the advantages of combining both into a more complete package were too great to ignore and they were consequently positioned closely together. It was recognised that there was a need to integrate the content, with the flyers becoming the theoretical underpinning of the (practice-based) videos. This reciprocity would enable the easy cross referencing of material from one format to the other. If a theoretical term arose within a video, it was important that a quick and easy definition was available from the flyers. Similarly the videos should contextualise underpinning theory found in the flyers.

Deciding on topics

The starting point for establishing what topics should be prioritised in the videos and flyers was the daily practice of the project leaders and authors of this paper, Teaching and Online Consultants at the Massey University Albany Campus. We were guided firstly by our perceptions of professional teaching development needs and of which resources would thus be most useful in our daily practice with academic staff. We also needed to consider the ‘big picture’: how the resources would fit with the overall staff professional development approach and offerings, and how the resources would be used. Key questions for consideration included:

- What professional development themes and issues were arising regularly in dealings with teaching staff, as well as in conversations with learning consultants about student issues?
- What tools would be useful when working with teaching staff, i.e. what could be given to staff as a “takeaway” from any professional conversations and/or workshops?
- Where did topics fit in terms of the domains and criteria for the Ako Aotearoa National Tertiary Teaching Excellence Awards (Spiller, D. et al, 2011), used as a framework for the Massey model of teaching?
- How would these resources reinforce teaching and learning techniques necessary for the 21st century, ie active, flexible and social constructivist learning that models and embeds the use of educational technology?

With these questions in mind it was possible to work through further details around which audience the resources were to target, and the purpose and approach of the resources. It was agreed that the resources would target multiple audiences and provide a showcase for effective practice occurring at Massey. Three target audiences were identified: Massey staff new to teaching; Massey academic staff looking for ways to change their practice, particularly those attempting the move to blended delivery; and the wider public, particularly tertiary educators. It was evident that, through highlighting specific acts of teaching, and articulating effective pedagogy, one main purpose of the videos and flyers would be to provide a useful resource for Teaching Consultants to “surface and resolve tension around teacher beliefs” – a significant first step towards change in teacher practice (Steel & Andrews, 2011, p. 247). They would also support Teaching Consultants’ demonstration of and promotion of ways to provide the kinds of “participatory, facilitated learning environment” essential for 21st century teaching and learning. (Diaz et al., 2009, in Steel & Andrews, 2011, p. 246). To remain consistent with the Massey approach to teaching, topics needed to be organised according to the Ako Aotearoa domains - Design for Learning, Facilitating Learning, Assessing Student Learning, Evaluating Teaching and Learning, Professional Development and Leadership. Finally, the videos and flyers needed to be closely aligned, with practice articulated in the videos demonstrating concepts in the flyers. It was important that the flyers offer an easily accessible, comprehensive glossary of key concepts and cover a wide range of teaching and learning terms and topics so that academic staff could gain basic information quickly, including how and where to get further information and help.

Video design

The format of the videos was described in general terms in Massey's priority initiatives document (2012b). They were to be brief (five to ten minutes each) and feature interviews with leading Massey practitioners talking about innovative aspects of their teaching practice. However, the document provided no definition or specific details of specific topics these experts were to talk about. Having considered established general parameters for topics, based on our daily practice as Teaching Consultants, the next step was to establish criteria for deciding specific topics for videos and flyers. The video interviews needed to cover:

- genuine teaching and learning strategies that met Massey expectations and desired outcomes
- demonstrable, specific and effective acts of teaching
- key content that matched the theoretical underpinnings of the flyers
- domains used as criteria for the Ako Aotearoa National Tertiary Teaching Excellence Awards

Video topics were thus drawn from the Ako Aotearoa domains using guidelines for effective teaching practice articulated in the *Portfolio pointers* (2011) to flesh them out. For example, points around encouraging active learning, creating and fostering unique learning environments and responding to feedback, guidelines specified in the Design for Learning domain, were combined to form the video entitled "Engaging students in the learning process." These points were then used as the basis for interview questions focussed on key areas of content. For ease of management and consistency, it was decided that there would be five open-ended questions per topic. At this stage feedback was sought from colleagues within both the National and campus-based Centres for Teaching and Learning on appropriateness of topics, key content and questions.

Identification of suitable participating staff was the next task. Selection criteria included those who had won internal Massey and/or external national teaching and learning excellence awards, staff that the Albany Teaching Consultants had worked with and thought displayed exceptional teaching skills, and those recommended by colleagues through targeted feedback. These people were then approached via email to gauge their willingness to participate, and those who expressed interest were sent a more comprehensive outline of what was involved including: the topic of the video, an outline of the key content they would be interviewed about, and the five key questions they would be required to answer.

Flyer design

The layout "look and feel" and content of the flyers were developed in close consultation with Massey's Materials Production Unit and the Centres for Teaching and Learning of each campus. Using a discussion forum in the Centres for Teaching and Learning online learning environment, both Learning and Teaching Consultants gave initial feedback on three draft flyers over a period of two weeks before any further development was undertaken. This process identified key elements to incorporate in the design of all subsequent flyers. The process also created a norm of, and process for, on-going feedback and collaboration which in turn enhanced a sense of shared ownership of the flyers among all Learning and Teaching Consultants. Such ownership is essential if the resources are to be used widely and effectively by these professionals in their day-to-day dealings with academic teaching staff.

Where to from here?

Planning was completed and videoing commenced in June. The first two videos and accompanying flyers were ready for use by October. By the time of the paper presentation, the authors expected to be able to report orally on progress with production, deployment of the resources, feedback received and initial evaluations. Given the project's alignment with principles for sustainable change creation including strong support at significant leadership levels, they expected to be able to report positive progress in their quest to support teachers' development into future makers for Massey University.

5 innovative ways to use virtual classrooms in Higher Education

David Spann
Curtin Teaching and Learning
Curtin University

With constant pressure for higher education institutions to increase (or at least retain) student enrolments across the sector, many institutions are opting to keep up with demand by offering alternate methods of education provision and facilitation. By providing tools and resources such as Blackboard Collaborate and Blackboard Mobile Learn, staff are able to engage and communicate with their students; anywhere and anytime. Encouraging staff to move away from the traditional lecture-theatre and tutorial based model and to instead embrace the opportunities provided by a virtual classroom is not always easy; however some staff have been re-invigorated by this teaching method and are trialing new and innovative ways to teach their students virtually.

Background

Curtin University has been utilising web conferencing for a number of years. In 2006 a 50 seat license for Elluminate *Live!* was purchased in order to trial using the software with a common 3rd year Business Capstone unit delivered through the Curtin Business School. In 2009, following the success of the initial trial, a business case was put forward to adopt Elluminate *Live!* throughout the Business School. In 2010, the rest of the university followed suit and a site license for the whole campus was purchased. The product moved to a managed hosting environment and was also integrated into the Blackboard Learning Management System. In May 2012 the university made the decision to upgrade from Elluminate *Live!* to Blackboard Collaborate and we are currently using Version 12 .

Usage statistics show that there has been constant growth and utilisation of the tool, particularly since it was rolled out to the whole university in 2011.

Period	Rooms Started	Max Concurrent Rooms	Re-joined Attendees	Unique Attendees	Total Attendees	Recordings
2008 - 2009	0	0	608	5747	6355	0
2009 - 2010	902	7	1799	6220	8019	50
2010 - 2011	2124	8	1394	7672	9066	905
2011 - 2012	4945	15	2302	14165	16467	2225
2012 - 2012	4516	13	923	9976	10899	1521
	12487	15 (max)	7026	43780	50806	4701

Trends and new usage patterns

From 2008 to 2011 the virtual conferencing software was primarily used to:

- conduct and record online lectures
- facilitate online meetings (between students and staff members, or internal staff meetings), and
- provide virtual office hours to students studying externally, allow them the opportunity to ‘drop in’ and ask questions.

Since then, a number of staff have trialed using the software in a number of unique (or non-traditional) ways; taking advantage of the new functionality provided to enhance their teaching and learning practices. Some examples of how the tool has been utilised at the university include the following.

1. Combining on campus and online students

A lecture in Sexology is bringing together the online and face-to-face students by conducting a weekly Blackboard Collaborate session during the on-campus tutorial. A webcam is pointed towards the class and the Collaborate session is projected onto the screen in the seminar room. The online students take part in the tutorial by asking questions and communicating and interacting with the lecturer and fellow students. The sessions are also recorded, ensuring that the recorded lectures can be used for revision purposes and are accessible to students who were unable to attend.

2. Library online training sessions

Library staff constantly receive questions from online students asking how they can use the library, and its resources without coming onto campus. As a service to the students library staff run training sessions using Bb Collaborate where students are shown how to browse the databases, catalogues, and e-Reserve as well as informing them of information retrieval resources that are available to them. This is predominately achieved using application sharing and web tours where the staff present a demonstration and then the students application share and demonstrate what they have learnt.

3. Using a tablet and stylus for calculations

A lecturer in Mechanical Engineering has trialed the use of a stylus and WACOM tablet in Bb Collaborate. In on campus tutorials, the lecturer would use a traditional whiteboard to set engineering problems for his students to solve. He would then demonstrate the solutions using prescribed formulas learnt throughout the semester to arrive at the correct answer.

He wanted to take this traditional technique into the online environment and to use the virtual whiteboard instead. The decision to use a stylus with the virtual whiteboard was made very early on; as writing calculations on the whiteboard area with a mouse proved to be extremely difficult. The recorded sessions then provided an excellent revision tool for all the students.

4. Creating student presentations and recordings for assessment

The UniReady Program (http://curtin.edu.au/uniready) is a short program consisting of six online units which, on completion, provide alternative access into Curtin University. Within the online program students are required to use Bb Collaborate to meet and work on group projects. Once the project has been completed they access Bb Collaborate as moderators conducting and recording the group presentation as part of their assessment. Students are allowed multiple attempts at producing the best possible presentation, prior to the assignment due date. Once groups have created and reviewed their recordings, they nominate the recording that they like the best and then submit the link to the recording to their tutor.

5. Managing regional and international staff

Bb Collaborate is also being used extensively for tutor meetings where teaching staff of large units located all over the world are brought together to discuss strategies, identify how the unit is managed, conduct moderation of assignments and exams and define unit administration processes. Application share is often used to show sample assignments or exams, collaboratively construct marking guides or rubrics and to achieve a uniform marking and feedback strategy.

Conclusion and future plans

The provision of training and support to staff around Bb Collaborate is an area that has proved vital in encouraging the successful use and adoption of virtual classroom software. Professional development is provided throughout the semester in a number of formats including face-to-face computer workshops as well as online tutorials run virtually in Collaborate.

As the tool grows in popularity and demand, more innovative ways using Bb Collaborate are surfacing and being trialed by university staff. It is envisaged that successful case studies will be captured and shared among the Curtin community via the 'Showcase' section of the Curtin Teaching and Learning website (http://blogs.curtin.edu.au/cel/showcase/).

With the release of a mobile version due later in 2012 the accessibility and adoption of virtual classroom software is likely to increase dramatically. Along with the implementation of mobile access, Curtin also intends to investigate the introduction of Blackboard's Instant Messaging system which connects directly into Bb Collaborate and the LMS.

Macquarie University

Michael Ireland
Macquarie University

Mark Wardle
Macquarie University

There are numerous challenges facing a class at university: limited access to tutorial rooms, fewer tutors and low student attendance in traditional lectures. A further challenge in science is the need to facilitate the learning—and develop the science literacy—of non-science majors, who in the case of this paper elect to study astronomy as part of their academic program. On moving a class online, the challenge includes finding, and becoming confident in using, effective methods and tools. This paper traces a process of review and collaboration between an educational development team and faculty academics to reconfigure an introductory astronomy unit. Part of the approach is to engage students using concept mapping to underpin enquiry-driven pedagogy using the university's learning management system.

Keywords: concept maps, peer instruction, educational design, astronomy, science education.

The Project

The project started with a teaching development grant in mid 2011 that brought together an Educational Developer (ED), Online Educational Designer (OED) and Convenor. The aim was to investigate how to take an introductory astronomy unit into a blended mode in Semester 2, 2012 and prepare for a wholly online unit in 2013, for students majoring in both science and non-science subjects.

A number of meetings over several months followed a process of sharing issues, perspectives and ideas, leading to a draft plan for the unit. The educational designers needed to understand the Convenor's style, perspective and issues with the unit, as well as her ideas for its improvement, while the Convenor needed time to understand and experiment with unfamiliar teaching approaches, such as the use of concept mapping and the various inter-connected technologies which would support individual and group enquiry-based learning.

The Unit

The Convenor reported a belief that students memorise facts but do not understand the inter-relationships of scientific phenomena. While they could demonstrate knowledge of individual aspects of astronomy, they often struggled to explanation how solar systems and planets develop and work in connection with each other. Students had reported trouble dealing with the volume of material covered in the course. Those with a non-science background, in particular though not exclusively, lacked tacit knowledge and carried a measure of naïve misconceptions. Although the Convenor was highly rated by students as a lecturer, many key concepts were not understood sufficiently, resulting in low test scores. The Convenor was already in the process of reducing the spread of content and increasing the depth in which some concepts were explored, but at the same time wanted to develop a framework which would promote active learning.

In end-of-semester surveys, students reported being unhappy with the limited tutorial support afforded by the unit: in a previous year tutorials ran a few times per semester and in 2011 there were none at all. A significant proportion of students did not attend lectures, and the audio recording of lectures was perceived as inadequate because lectures feature live prop-supported demonstrations.

As a popular introductory course open to students from across faculties, the plan was to make it available as a fully online offering. The unit required a new approach to delivery, student support and assessment.

From the Literature

The aim for the unit was to facilitate deeper understanding. Meyer and Land (2006) describe a threshold concept as one that is likely to be 'troublesome' for students to grasp in that it runs counter to their preconceptions, but that can be transformative and 'exposes the previously hidden interrelatedness of something' (p. 7). In dealing with threshold concepts, Meyer and Land advocate active learning methods and creative tasks to encourage understanding. It is challenging work to construct new understanding.

The practical application of constructivism in education has been problematical (Perkins, 2006); it is easier to 'talk the talk' than 'walk the walk'. Perkins highlights the importance of bringing tacit knowledge to the surface by asking students to discuss their ideas, that is, by 'surfacing and animating' the tacit knowledge, students 'play the game knowingly' (p.40), developing metacognitive skills. More specifically, the teaching of science to non-science majors has been a problem acknowledged by a number of scholars (Prather et al., 2004). Mazur (1997) suggests memorisation tends to be the way students tackle subjects like physics or astronomy, leaving them with little true understanding of the basic laws and concepts. This aligned with the Convenor's observations.

We decided to use in-lecture questioning and concept mapping. Concept maps have been used in a number of introductory university astronomy classes (Newbury, 2010; Zeilik, n.d.). Concept mapping enables students to organise and explicate knowledge, highlight gaps in understanding and provide a shorthand visual representation of non-linear knowledge (Novak & Cañas, 2008). They differ from less structured mind maps by generally answering a specific question and joining concepts by 'linking words or phrases', forming 'propositions' (Novak & Cañas, 2008, p.1; see figure 2). The Convenor was especially interested in how the maps make student knowledge visible, showing how students' conceptions develop and helping identify material that might require further support in lectures or through online resources. Concept maps would be constructed in groups, with the associated student-to-student explanations, debates and negotiated answers.

Peer Instruction (PI), developed by Mazur (1997) for the teaching of physics and adapted by Green (2002) for astronomy, involves asking a question that integrates the previous 10-15 minutes of lecture material, where each student answers individually first, discusses with neighbours and then answers again. It is also called 'think-pair-share' (Prather, Rudolph & Brissenden, 2009, p.43). The value is in having to articulate the knowledge and hear an argument from someone at a similar conceptual level, rather than passively listen to a lecturer (Mazur, 1997). We purchased clickers to use in lectures to gather responses and to evaluate the type of questions that promote productive results (for example, questions that elicit around 30-70% initially correct answers from individuals (Mazur, 1997; Green, 2002)). When the unit is wholly online, this approach and findings will inform how we set up the online environment. Lecture-tutorials (Prather et al., 2004), in which students work in lectures through a series of problems that build upon each other, may also be adapted for online interactive exercises. The Moodle Lesson module was identified as one possible method for this.

Our re-development approach

Example of concept map development in the project

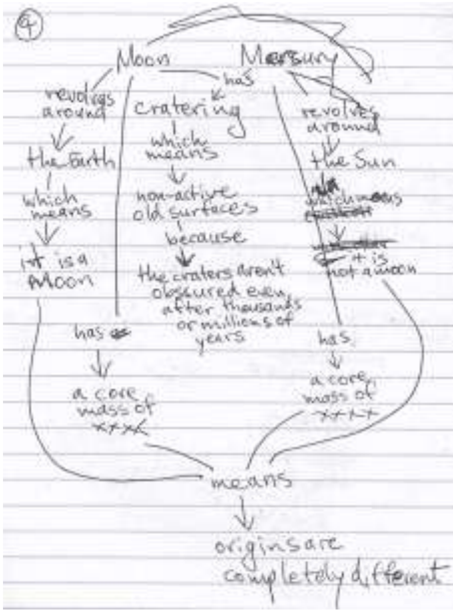

Figure 1: Initial freehand concept map attempting to answer: 'The Moon and Mercury look alike, but how are they different?'

From the outset, the team worked in small stages, with regular meetings to explore ideas and allow the Convener to experiment with the various elements being proposed - both technological and pedagogical. This process provided a context to critically review existing materials and to assess their potential to be re-used or omitted in the new schema, for example dropping details of some of the gas planets. The review was for relevance to learning objectives but also to consider their discover-ability by the students using the concept mapping scaffold being developed. This strategy was used to reduce the 'taught' material such that students are afforded the time to find linkages, gaps and relevance between concepts, ideas and observations.

The Convenor made a journey with the ED on the idea of concept maps. A significant enabler of the project was her openness to exploring unfamiliar educational theories and their relationship to proposed instructional technologies. As educational theory is itself broad and contested, we see constructivism, like Perkins (2006), as 'more like a Swiss army knife with various blades for various needs' (p. 45) and worked to apply solutions to our specific situation.

In our process it was vital to include the Convenor as an integral part of the design team. For example, the Convenor developed ten draft questions for the proposed concept map assessment task. The OED, in the role of novice-student, attempted to create the concept maps freehand (figure 1) and then using the free software CmapTools, based on the guidelines of Novak and Cañas (2008), hints from the Convenor and a certain amount of Googling. This proved a good, quick way to test the idea and to give the Convenor a better view of how concept mapping might work. Later, the OED and Convenor worked together on refining the map (figure 2). While this did not mirror exactly the planned peer-to-peer interaction of the assessment task, the experience of talking through the ideas and how to map their relationships was a reassuring confirmation of the value of dialogue in knowledge creation through the collaborative development of mediating artifacts (Paavola & Hakkarainen, 2005).

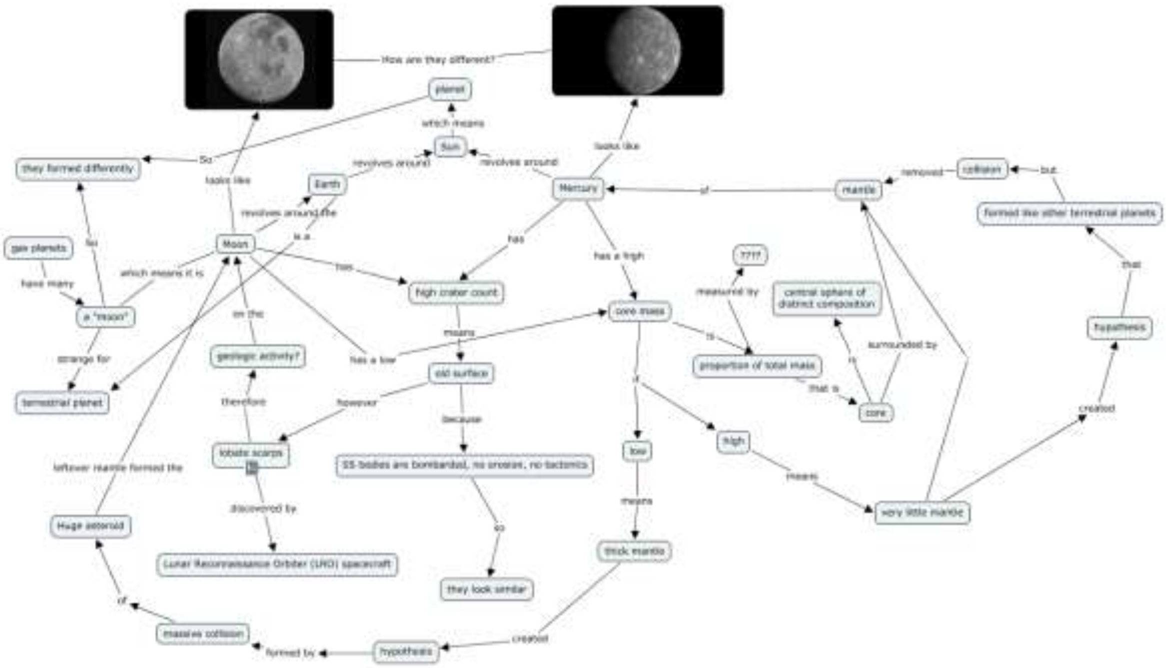

Figure 2: A more detailed concept map created in CmapTools (http://cmap.ihmc.us/)

A sustainable approach

Increased support for students can be achieved through several approaches, including making lectures a little more tutorial-like through peer instruction, teaming students in groups to work on concept maps, formative feedback and through offering online tutor-attended chats at specific times.

There were a number of strategies to enhance sustainability and lower barriers to adoption. One approach was that of minimising the changes needed to lecture material. PI and lecture-tutorials can be utilised with existing lecture materials with minimal work. As there are problems and questions already developed for astronomy, together with guidelines in their use, they won't need to be developed totally from scratch. This is a less confronting or time-consuming way of introducing change, as Lecturers can still use most of their existing lecture material and benefit from the experience of tested methods. The Convenor will not teach the first offering of the unit with the planned changes, so introducing the Lecturers to the fundamentals and bringing them to a level of comfort with the approaches is a further strand to the project.

We aimed to fit activities, marking time and online support for tutorials within available resources, balancing the need for tutor access and feedback with an acceptable budget. Calculations were for a cohort of around 250 students (session 2, 2012 ended up with enrolments of over 400) working in groups of eight, with a non-compulsory weekly one-hour tutorial, repeated four times a week, run by synchronous online chat.

We put the three existing paper quizzes online, using only questions within the automatically marked options available within Moodle, the LMS, removing short answer questions. This freed up some marking time for formative feedback on group work.

A new group project based on concept mapping and pieces of related and reflective writing was introduced, with each group receiving two instances of short formative feedback before final submission. While group work helps manage marking time for large cohorts, we wanted to ensure that groups were given assurance and support in doing the unfamiliar task of mapping. Each student is also required to produce a short reflection on their role in the group project, which gives students a chance to outline their project 'soft' skills and is a source of information for us on how the task worked from their perspective.

Re-development of learning materials

The default recordings of lectures are audio with computer screen capture. A number of the key concepts in lectures are demonstrated with props and physical enactments, which will need to be captured on video (which may be 'quick and dirty' webcam productions) and/or supplemented by existing or created online animations and interactive questions. It is important that the Lecturers and Convenor are able to create video content themselves. A learning and teaching centre video production support project is developing training and resources.

Support materials for students on how to collaborate, build concept maps and use concept-mapping tools were developed by the OED. They are fairly generic, so can be re-used in other units. The OED has also produced an animation to support the unit's practical assignment involving mapping the phase and position of the moon over time—a troublesome task that requires some reorganisation of spatial concepts in order to plot on a sky map.

This unit is being delivered in a blended mode in Semester 2, 2012 using online group collaboration and tutorials. In addition, some remote students–and a proportion of on-campus students–are participating without coming to lectures. Another step in the iterative re-development of the unit.

Review It: a learner-led course evaluation

Ralph Springett
Massey Extramural Students' Society
Massey University

Murray Kirk
Massey Extramural Students' Society
Massey University

Review It is a learner-led course evaluation tool providing advice from students to students who are finalising paper/offering choices as they progress through their study. Review It encourages reflection of the student's learning experience, and asks what advice that student would give other students. Survey results are moderated and made public online. By directing students to consider how they engaged with the learning material and delivery of an offering, Review It provides prospective students insightful advice from a student perspective. Students may also choose commend a lecturer or offering. The Review It question line also captures student perceptions of weekly workload, how close the offering matched their expectations, and whether there were unforeseen additional costs in study materials and resources. The benefits of the survey extend both to students and the institution; students have access to first-hand course testimonials, while the institution benefits from the first hand reports of students' satisfaction or dissatisfaction with their courses.

Keywords: course review, learner-led, Review It, course advice, student reflection.

The Review It Survey

Review It is a learner-led course evaluation developed by EXMSS with support from Ako Aotearoa. Review It provides advice from students to students who are finalising paper/offering choices as they progress through their study. Review It encourages reflection of the student's learning experience, and as a part of that process asks what advice that student would offer other students. Survey results are moderated and made public online.

Perceived Need

In 2010 EXMSS developed Review It in response to enquiries from distance students who did not have the benefit of advice from face to face discussions with classmates about what elective papers to take as they progressed through their degree. Distance students consistently place a high value, and comment positively, on the Review It service.

Review It Survey Goals

1. Provide students with trustworthy and relevant advice that assists students in making paper choices;
2. Provide an opportunity for students to reflect on their learning experience;
3. Make available to lecturers feedback that may help improve future delivery;
4. To ensure the needs of all stakeholders are balanced with the project outcomes; and
5. Offer an opportunity for students to recognise individuals that have contributed to an exceptional learning experience (and recognise a good learning experience itself).

The Review It Cycle of Contribution and Support

In order to deliver on the Review It survey goals a cycle of contribution and support, of giving and receiving, has been developed. This enabled the question line to be considered in terms of two-way engagement and necessitated consideration of both what the student is seeking as information and what the student would benefit from giving.

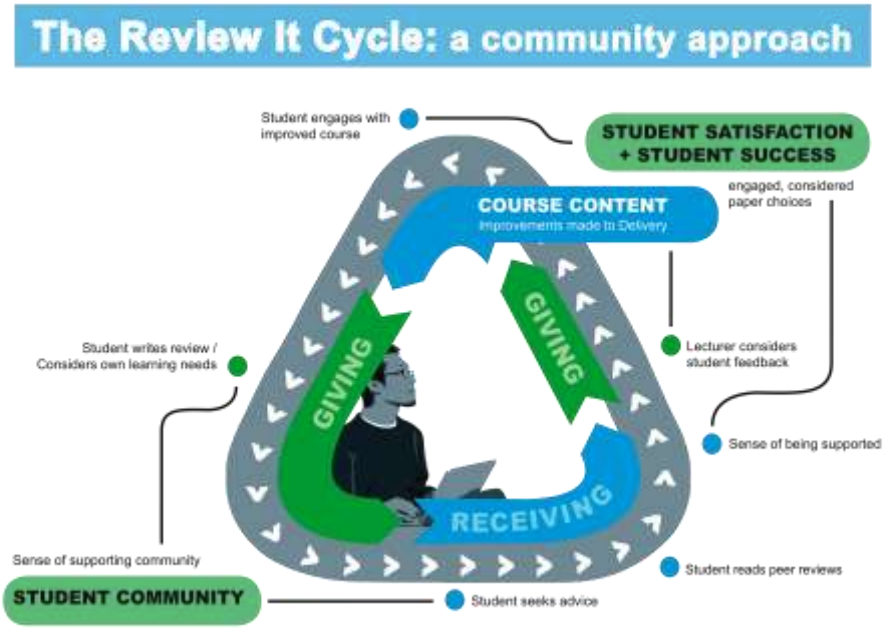

Figure 1: The Review It Cycle of Contribution, support and Improvement

Offering an Ongoing Cycle of Improvement

Part of this Review It cycle involves an opportunity for lecturing staff to review the course content and delivery in light of feedback received. Lecturers who make changes to course delivery have the opportunity to place feedback on Review It results pages. The public nature of the survey adds an element of scrutiny not present in most institution surveys.

The Survey Process

Students are invited via email to review the papers/offerings they are enrolled in. Surveys open for approximately six weeks and close following the release of examination results. Reminder emails are sent prior to the close of each survey. Student media announces when the survey results are available online.

The Survey Questions

Question Text	Answer style
On average how many hours of independent (not tutorials, lectures or labs) study per week was required?	
Other than the fees were there additional costs (such as textbooks, fieldtrips, contact courses or lab costs) for this paper?	
How would you describe the learning resources (printed and web material) of this paper?	Four point scale
How would you describe the process of assessment for this paper?	Four point scale
How would you describe the academic support for students in this paper?	Four point scale
Thinking about the previous questions, if you were to describe your academic experience in this paper what would you say?	Free text
The thing that helped my learning most was…	Free text
The thing I would like to see improved is…	Free Text
Would you recommend this lecturer for ‘lecturer of the semester’?	Yes/no
Would you recommend this paper for ‘paper of the semester’?	Yes/no

University Support

Massey University provides the database that Review It utilizes to complete each survey. Without institutional support the Review It would not be able to operate.

Best Paper, Best Lecturer

Awards are generated and presented annually for Best Lecturer and Best Paper as determined by student feedback. These awards are the students' opportunity to publically recognise good teaching.

Student Comment Moderation

Student responses remain anonymous. Prior to publication, survey comments are moderated
Moderation Guidelines. Comments should:

- Focus on the learning experience;
- Not speculate on or presume the reasons why an offering was delivered in the way it was;
- Offer constructive advice;
- Be free of expletives and terms that are generally considered offensive;
- Be free of libellous, personal or derogatory comments;
- Not disclose information that is private or personal;
- Be free of comments that contravene human rights; and
- Not name and shame.

Data Use and Ethics

Students agree to terms and conditions that allow the use of data for research. Ethics approval for the use of the Review It data has been granted.

Conditions of Publication

Moderated results will not be published if the number of respondents is less than 5% of the enrolled numbers or if there is only one response.

Conclusion

Review It, with its offering-specific feedback, takes student reviews a step further. Not only does it inform students' academic choices at offering level, it supplies a real connection between students' experiences, and the lecturers who are seeking to satisfy both the learning requirements and the students' desires for a positive learning experience.

Fitting learning into life: Language students' perspectives on benefits of using mobile apps

Caroline Steel
School of Languages and Comparative Cultural Studies
The University of Queensland

For university students, the availability, convenience and low cost of mobile applications (apps) present new opportunities to fit learning into their busy lives outside class. Studies of teacher-led mobile learning in universities abound while few studies explore students' own use of mobile apps and their perspectives on how these apps can benefit their learning. As we consider learning for the future, it is crucial to partner with students to build a picture of emergent technology practices beyond our classrooms and institutions. However, discipline-specific studies are required to gain an understanding of the ways apps are used to acquire specific disciplinary knowledge and skills. This paper reports on how 134 language learners used mobile apps to profit from their available learning time outside of class. It provides insights into student perspectives on the benefits of using mobile apps for foreign language learning.

Keywords: mobile language learning, MALL, language learning, student perspectives, university

Introduction

> Pockets of time available at certain times of day can become profitable moments of learning, and places that were previously dedicated to one purpose can assume a different role.
>
> Kukulska-Hulme, 2012

Beyond formal institutional settings, university students make their own choices about how they fit learning into their busy lives. Some five years ago, James, Bexley, Devlin and Marginson (2007) reported that 70.6% of full-time Australian undergraduate students worked an average of 14.8 hours per week with nearly 20% working 16 to 20 hours per week during semester. Recent surveys (Coates, 2011) have shown similar trends. On top of university studies and work, students need to juggle other aspects of their lives including friends, family, social and other commitments. Our busy students need to find ways to 'fit' learning into their lives. For students, mobile devices are obvious tools that can help maximise their time-on-task wherever and whenever there is time and opportunity to learn. Pricing and mobile connectivity for these devices is rapidly becoming more accessible to students. Smartphones now outnumber laptops and ownership is exceeding saturation (Traxler, 2011). In Australia, smartphone ownership increased by 36% from 2010 to 2011 and is predicted it to grow to 60% of the Australian mobile population by 2012 (Telstra, 2011). Simultaneously, mobile applications (apps) are proliferating exponentially and experiencing extremely high take-up with predictions that they will soon eclipse desktop computing (Perez, 2010, Godwin-Jones, 2011).

For our busy university students, mobile apps offer a wide range of learning tools they can be downloaded to their mobile devices and used productively at opportune times in a variety of settings and on-the-go. Yet few studies have investigated students' personal use of mobile apps for learning and the learning benefits students perceive for their university studies. Indeed most studies of mobile learning in university settings have tended to focus on teacher-led mobile initiatives. Disciplinary context is also often overlooked. The discipline is important here as learning is experienced differently in different fields of study. This paper reports undergraduate students' use of mobile apps for foreign language learning. It describes how students use their apps to maximise the effectiveness of their out-of-class learning time and how students perceive these apps benefit their foreign language acquisition.

The nature of foreign language learning outside class

Learning in different disciplines is dependent not just on how students learn but also on what they learn. Whilst more generalist educational theories such as Social Constructivism have broad applicability for language learners, the ways in which students acquire languages has demanded language specific learning theories (Chapelle, 1997, 2005). More recent examples of these theories include Second Language Acquisition Theories (SLA), Communicative Language Teaching (CLT), Content and Language Integrated Learning (CLIL) and Intercultural Language Teaching and Learning (ILT) (for an overview of these theories see Lo Bianco with Slaughter, 2009). Such theories highlight a range of pedagogical approaches that were created specifically for the discipline of language learning with a view to language acquisition.

Extending language learning outside of classroom time, especially where in-class language practice time is limited, is essential to language acquisition (Kennedy and Levy, 2009). Foreign language mastery requires frequent informal practice (Kukulska-Hulme, 2012). In non-language-immersive environments this means trying to maintain a more continuous connection with the target language by locating time and opportunities for self-regulation and practice. In this context, mobile devices and their applications hold potential affordances for language learners (Kukulska-Hulme & Shield, 2008). In relation to these affordance it is useful to consider major language areas and skills that are central to language acquisition. Levy (2009), discussing computer assisted language learning, categorises these areas and skills as grammar, vocabulary, reading, writing, pronunciation, listening, speaking, and culture. This study considers these areas and skills in terms of students' reported use of mobile apps and the learning benefits they perceive. The types of apps that are used by language learners are described in the student quotes in the results and findings section.

Methodology

A mixed methods research project called 'The beliefs and experiences of language students in their early years of transition to university-level study' was conducted at an Australian university from May to August 2011. Employing an online survey, 2,114 language students were invited to participate and a 28% response rate (N=590) was achieved. Ten foreign languages were represented across the sample with highest representation from students studying French (175), Japanese (163) and Spanish (116) (see Figure 1).

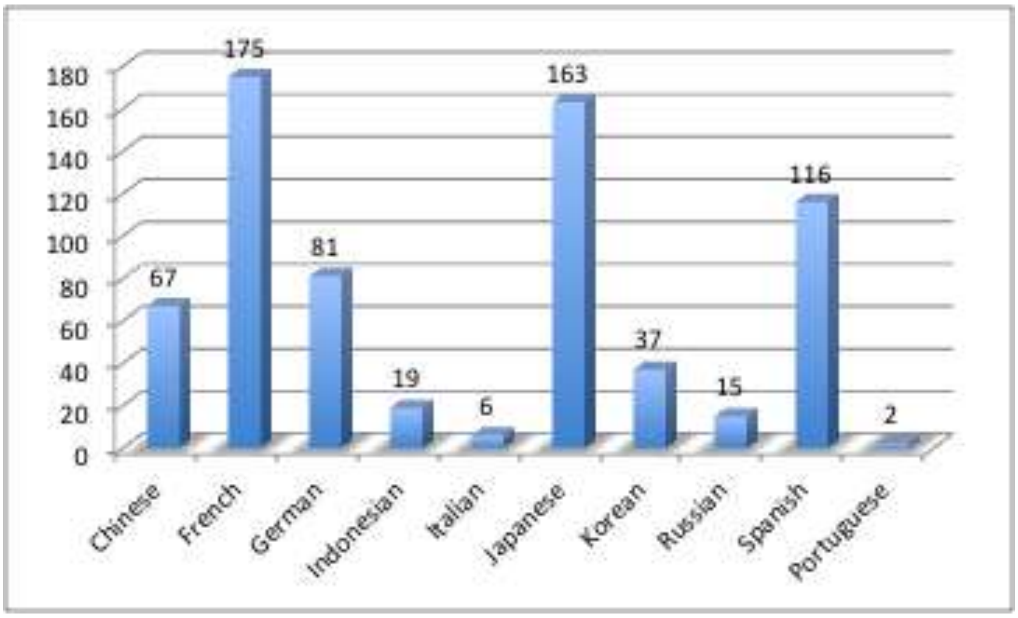

Figure 1: Languages studied across the sample

In one section of the survey, students were asked to identify the technologies they used to support their language learning (inside and outside of class) and then rank the top three technologies they perceived as most beneficial to their language learning when used outside their formal class settings. Students were then further prompted to type qualitative comments explaining the learning benefits they perceived from their top three technologies.

Whilst 331 (56%) students reported using mobile apps to support their university learning, 134 (23%) students ranked mobile applications in their top three technologies. Qualitative analysis was conducted inductively on student comments to find out how students use mobile apps to profit from learning time available outside of class and the benefits they perceived from using mobile apps for language learning. Data was handled interpretively through different levels of coding, categorisation and reduction until clear themes emerged. This analysis is ongoing and preliminary results form the basis of the discussion below. The themes reported describe: (a) the ways students used mobile apps to maximise time, location and opportunity to fit language learning into their daily lives, and b) the specific learning benefits students perceived through their use of mobile apps for language learning.

Results and findings

Student comments on mobile apps highlighted some of the key overall advantages often associated with being able to learn on-the-go as well as learning benefits that enabled the development of specific language learning areas. The more general benefits are discussed first as they emphasise the ways that students fit learning into their busy schedules and utilise 'pockets of time' to connect with, and learn languages. The more language-specific benefits are then examined with reference to language learning areas and skills that students reported mobile apps helped address.

Fitting learning into life

The ability to practice language anywhere and anytime was a strong theme in the student data on mobile apps in this study. Students appreciated the flexibility and convenience of using their apps to meet their personal learning needs at times and in places that suited their lifestyles.

Students often mentioned the convenience of using their apps to gain time efficiencies thus exemplifying how students can utilise pockets of time profitably: '*I downloaded various dictionary apps for the language that I am learning so I can check and refer to it whenever and wherever I am. It is very convenient*'. Learners could embrace opportune moments in varied locations without a lot of forethought and preparation:

> Allowed me to build custom decks of kanji & vocab cards, which I can review nearly anywhere - on the bus, on a break from work or in-between classes. It's turned my transit time into 80% study time - a huge reclamation

Students often referred to the fact that they tended to carry a mobile device like a phone with them anyway which increased their access to their apps. '*I always have my phone with me so my phone apps for my language learning are with me as well'*. This kind of portability extended to their workplaces and enabled students to revise and review their in-class learning. '*It is accessible to me during brief breaks in my work schedule and allows me to revise points quickly*.'

Overall, students found mobile apps '*easy-to-use and understand*' and '*accessible anywhere anytime*'. Students commented that apps were generally free or low cost and '*are often many things in one: dictionary, text-book type exercises, flash cards, audio, writing practice devices etc*.' Additionally, students expected apps to continue to improve and to offer more opportunities for learning. As one student said '*there are so many apps out there that help assist me in my language learning, and there are always new apps being released*.'

Convenience, portability, and being able to learn-on-the go were important factors for students who ranked mobile apps as beneficial to their language learning. These features are not new to mobile learning and their benefits have been espoused for some time (e.g. Alexander, 2004). However, recent changes in the ownership patterns of smartphones, and the availability of a large range of mobile applications that cater to a wide range of languages has meant that this potential can now be realised by more university students studying foreign languages. Students in this study also realised the potential of being able to personalise their learning to achieve learning tasks quickly and easily, spontaneously and habitually, so that time could be used profitably for language acquisition. For learners in this study, being able to use one small and portable device anywhere and anytime meant that learning languages could be less compartmentalised and less tethered to time and place. This also meant that students could more readily immerse themselves in their target language.

Language specific learning benefits

Of the language areas and skills discussed earlier in this paper, mobile apps reportedly benefited most with vocabulary (particularly for memorization, accessing meaning and contexts for use) and with reading, writing, grammar and translation tasks. Specifically, apps that offered mobile versions of language dictionaries, translators and verb conjugators were indispensible when available via one highly portable device.

> Phone apps can be used as dictionaries, help with verb conjugation, hanja help (chinese characters) ... It's language tools whenever I need them, wherever I need them and that makes it really useful to have.

These kinds of apps enabled students to quickly and easily check the meaning of vocabulary whenever they needed to: '*if I hear a word that I don't know i can just easily look it up*'. And many students claimed that the use of these apps had a positive influence on their vocabulary acquisition. '*I was able to use these apps on the bus to and from university which helped me cement some vocabulary and grammatical skills*'. Facilitating vocabulary acquisition, on-the-go, also meant that students had more opportunities to remember words in context:

> When i want to know what a certain word may be for a situation and i am out and about i can look it up straight away. I find i remember it better because i can remember the situation as well, so i am constantly expanding my vocabulary.

Mobile apps for vocabulary acquisition (such as flashcards and games) were perceived as highly beneficial to students' learning. Many of the language apps offered flashcards and games that could be personalised to assist targeted vocabulary acquisition.

> I have an app on my phone which works exactly like an electronic dictionary for Japanese, except better. I can store vocabulary lists on it and it will make an automatic flash card game to help me memorise new vocabulary.

Many apps combined a number of features in one app which meant that students could use multiple functions in integrated and seamless ways. Reportedly, the availability of these functions helped their learning.

> There are several apps which have flash card or select the right answer games on important vocab or grammar, as well as supporting a dictionary/translator. I find these help solidify what is learnt in class.

> I have a mobile phone app that does everything. its a dictionary for both jap to english and then english to jap. it also shows examples of words in a sentences, you can look up kanjis, it shows functions and grammar formats. its just extremely helpful and i use it all the time

Students often related their use of apps to the content or the way they were learning in class. '*You can use them while travelling, makes revision slightly easier and can be fun*.' Sometimes, being able to work at their own pace rather than the class pace was perceived as beneficial '*it "teaches" me outside the classroom and at my own pace, as sometimes the lecturer moves too fast for me to understand*.'

Importantly, students valued the opportunity to intellectually connect with the language beyond the classroom. '*Sets me words to learn, quizzes me through flashcards and games on the words - gets me thinking in German outside the classroom*'.

Depending on the language under study, there are different linguistic characteristics and challenges. Being able to access apps that helped students directly with some of these known challenges was perceived a beneficial. For example, languages that were gendered or had character-based writing systems. '*I also have some language learning apps to help remember vocabulary and to help memorise gender of nouns - these are really helpful.* '*Applications allow users to handwrite simplified or traditional characters on the screen as an input option for dictionaries, along with pin yin or English typing*.' Locating characters in traditional dictionaries can take a lot of time, so being able to quickly search for and identify Chinese and Japanese characters was very helpful and time efficient. '… *it also has an excellent Kanji search that can be text based, multi-radical, JLPT level and a number of other ways*.'

Many students had a variety of language apps on their mobile devices. '*I have approximately 6-8 apps on my phone relating to language learning. These are dictionaries, flashcards, conjugating apps, games, mp3 etc*.' However, apps that promoted vocabulary acquisition were frequently mentioned in the student data. A potential limitation of this study though, was that most students (just over 70%) were in the first or second year of their university study. While some of these students may have been taking more advanced language classes based on prior studies or experience, it is likely that a majority of students were closer to beginner to intermediate levels. This may account, at least in part, for students' focus on vocabulary acquisition over say more authentic or communicative language learning. Vocabulary acquisition through mobile devices has been emphasised in other studies of mobile language learning (e.g., Levy and Kennedy, 2005; Thornton and Houser, 2005, Stockwell, 2007). However, few studies, with the exception of Song and Fox (2008) have reported on students' personal use of mobile devices to acquire new vocabulary (Kukulska-Hulme, 2012).

While other language areas were addressed, such as reading, writing, grammar and translation tasks, it was notable that few students mentioned using these devices that were originally intended for communication for phone calls and texting. Again, this could have been a constraint of the language levels surveyed. A further limitation may be the types of foreign language apps currently available to language learners and their pedagogical designs. Many apps are still designed using behaviourist algorithms.

Conclusions and implications

Kukulska-Hulme (2012, p.1) suggests that ‘by reviewing individual learner experiences in learner-determined contexts, researchers and the language teaching community can work together to build up a picture of emergent practices’. This study has contributed to understanding how foreign language students are currently using mobile apps to support their language learning. It highlights how these devices are making a difference to the ways that students fit learning into their busy lives as well as describing the dominant uses of these apps in the context of a specific discipline. For language learners and teachers the future holds great potential. As this student’s comment underscores:

> Mobile apps are beneficial because you can access them anywhere, meaning you are more effective with your time. Successful language learning occurs mainly in immersive type environments, so I think that mobile apps are most beneficial because they bring more exposure and engagement with the language than just the time spent in the classroom.

However, more studies of students’ personal use of mobile apps and devices are required for the discipline of language learning and for other disciplines too. For language learning, further studies could be conducted with more advanced language students to see whether there is more variation in their usage patterns and the skills and language areas that are targeted. Additionally, more studies need to examine the pedagogical premises that underpin the design of current mobile apps and to suggest improvements. For example, are language learning apps being developed based on narrow interpretations of language pedagogies and theories? Further, teachers need to be more aware of the language apps their students are using and how they are using them so they can provide some guidance and recommendations on how their learning benefits could be extended.

The affordances of web conferences in online pre-service mathematics education

Brett Stephenson
University of Tasmania

Jillian Downing
University of Tasmania

In their books ‘Teaching the digital generations: No more cookie cutters’ (2008) and ‘Windows on the Future’ (2001), Ted McCain and Ian Jukes discuss the change that is necessary in education to respond to technological change. Web conferences are emerging as an important pedagogical tool for pre-service teacher education. In this study pre-service mathematics teachers shared their views of the benefits and limitations that web conferences offer. The collection of data for analysis was from students experienced in web conferences and was obtained by, appropriately, a web conference where questions were presented on the web conference whiteboard and responses and discussion were given using the text, talk, polling and whiteboard tools embedded in the web conference software. This paper will provide a synthesis of the findings and explore the implications for online pre-service teacher education programs.

Keywords: Web conference, online learning, student evaluation, pre-service teachers, teacher education.

Introduction

It could be argued that the venue and structure of a mathematics class has changed little over the last one hundred years. The advent of increased technology into our society and the impact that will have upon a mathematics class is hard to predict. Online possibilities are plentiful but changes to incorporate this into schools have not been universally accepted. A person entering a mathematics class in the 21st century may see very little outward difference from the class of the 20th century and perhaps even the 19th century (McCain & Jukes, 2001). Other professions have changed radically in both equipment, style and environment (consider a doctor's surgery). The plethora of new technologies that can be utilised in a classroom are perhaps still 'hiding under a bushel'. Mathematics classes can still be viewed as a place where information is just transmitted and received (McCain & Jukes, 2008). The task to consider all of the new technology that could or should be incorporated into a new pedagogical approach for mathematics teachers would be enormous. This study considered a case study involving pre-service mathematics teachers at the University of Tasmania who had studied at least one secondary mathematics education unit online. The students were asked to discuss the benefits and limitations of web conferences that were experienced using Blackboard Collaborate Live (consisting of interactive chat, whiteboard, instant polling and live discussion) which had been used as part of their online secondary mathematics education units. The terms ‘web conference’ and ‘webinar’ will be used synonymously in this paper as both are used frequently by the participants. Pseudonyms have been used in this paper for the direct quotes from participants.

Literature review

The consideration that webinar and online class offerings may be an integral part of all classrooms in the future should not be ignored. Conclusions made after a trial of web conferencing software by the University of Queensland indicated that Blackboard Collaborate can enable new ways of teaching and learning as well as encouraging innovation pedagogical and collaborative teaching methods (Reuschle & Loch, 2008). An online professional development program for mathematics teachers in the United Kingdom (de Pomerai & Tripconey, 2009) received feedback about the use of Blackboard Collaborate for instruction. The collaborative nature and accessibility were seen as significant advantages whereas the lack of class type demonstrations and technology concerns were highlighted as disadvantages of this program. The individual tools within Blackboard Collaborate such as the audio, the shared whiteboard and application sharing were mentioned but not analysed or compared. A study of synchronous and asynchronous online learning (Ichinose, 2010) indicated that synchronous online activities were effective in teaching and learning mathematics. Previous studies (Collinson, Elbaum, Haavind and Tinker, 2000; Cox, Carr & Hall, 2004) saw the asynchronous nature of online learning to be a leading motivator for course participation. The capacity of Blackboard Collaborate to be able to be used synchronously and asynchronously (as a recorded class) could provide a good balance.

Web conference questions

The starting point for the research was a web conference where a semi-structured interview was initiated with the participants. The whiteboard, polling/voting, talk and chat tools were used with the participants in the web conference to record the responses for the four qualitative and two quantitative questions. The category of research was expected to be predominately descriptive and a qualitative analysis of the descriptive responses would be conducted. Questions using the polling tool obtained some Likkert data for quantitative analysis. The audio recording of the web conference was used to procure data for the study.

Qualitative questions

Q1. In what ways do you consider the webinar class different to a face to face class for studying techniques and knowledge about mathematics teaching?
Q2. What do you consider are the benefits of studying mathematics education in a webinar class?
Q3. What do you consider are the limitations of studying mathematics education in a webinar class?
Q4. Which of the tools in the Collaborate program do you consider most useful in being able to study the teaching of mathematics?

Quantitative questions

Q5. Web conferences were beneficial to studying of mathematics teaching?

Strongly disagree	Disagree	Neutral	Agree	Strongly agree
○	○	○	○	○

Q6. I believe that I am likely to need to use a webinar in my future teaching career?

Strongly disagree	Disagree	Neutral	Agree	Strongly agree
○	○	○	○	○

Methods

Research site and the participants

This research study took place at the Faculty of Education at the University of Tasmania. The University of Tasmania is a mid-size university in Australia catering for approximately 15 000 full time equivalent students. The faculty has an enrolment of approximately 1900 full time equivalent students. The students who participated in this study were enrolled in at least one of three units in secondary mathematics education that form a part of the Master of Teaching course during 2011. These three courses are usually studied sequentially over an 18 month timeframe and are compulsory units to qualify as a teacher of mathematics at high school level. For this study, six students volunteered to provide in depth feedback on their experiences with web conferences. The web conference to obtain the data for this research was held on Wednesday July 4th, 2012. The web conference was recorded and verbal responses were later transcribed. . The verbal responses and the text responses formed the majority of the data for analysis.

Findings

The students in the study indicated that web conferences provide a positive connection between both the students themselves and the lecturer. It was readily apparent that isolation was a common theme when online courses did not include web conferences for these participants. The personal nature and connectedness that were important features of the web conferences and that had been identified in other studies (Reuschle & Loch, 2008; den Exter et al, 2012). A comment from one of the students typified their views:

> Being an online student you can feel very isolated. The webinars have been really helpful in feeling connected. The feeling I have is that the setting is more intimate than a large lecture, with more interaction than in a regular setting. This has made learning the content more interesting and hence easier to assimilate. Also you can ask questions or participate without feeling like everyone

> is looking at you. (Mark)

Students who had completed online courses in the Master of Teaching program that did not have web conferences as a component commented on a feeling of isolation. There is evidence that a connection is established with the use of weekly synchronous web conferences (den Exter et al, 2012; Heirdsfield et al, 2011). It is generally agreed by researchers that knowledge is founded in discourse in social interactions and not just in the minds of individuals (Hrastinski, 2008). This capacity to connect with discourse and social interaction must be an important component of not only face to face classes but also of any online class. To support any online education, online participation must be encouraged and developed (Hrastinski, 2008). The design of the learning environment is important to encourage this participation and needs to support interaction from all participants using synchronous and asynchronous learning tools. Synchronous tools such as the web conferences have been successfully used with small and large classes to allow instant communication and promote collaborative learning (den Exter et al, 2012). Evidence that collaboration was used effectively was highlighted by one participant: “The webinars were definitely a step up from just having an online course. I liked having a ‘room’ where we as students could also meet at other times – we used it in the organisation of group planning assignments” (Jan). With the ability to meet in the 'web room' at any time the students had unlocked a potentially powerful collaborative student-to-student tool. The advantage of students being able to use a synchronous tool such as the web conference without the lecturer as well as the asynchronous use with the recording was further reinforced with comments from students such as

> The webinars have been great in the ability to offer distance students more collegial experiences than units that do not utilise them. The units that do not use them would benefit distance students by utilising them or at least by recording tutorials so that online students can observe (Peter).

Another communication benefit seen by students was the openness and freedom that the synchronous nature of the web conference allowed. This was well articulated by a student who stated that: “The webinar format allows you the freedom to question and discuss any areas of concern, and to use the whiteboard to clarify the issue” (Scott).

Although web conferences were seen as beneficial the connection to future teaching was not considered by some of the students interviewed. All of the students interviewed agreed that web conferences were personally beneficial with the majority strongly agreeing. Some benefits that were listed by students were related to classical distance education issues such as providing access for rural and isolated students. One of the students reported that

> I think the idea of a teacher standing up the front and talking to a set group of students may change in the future. Rural or isolated students would benefit. Being able to do special classes in a regular school would be cool. (Jan)

Some of the drawbacks that currently are preventing the use of web conferences such as technology were outlined in comments such as “teaching mathematics might be more challenging but only because I find using a mouse/trackpad gets in the way of drawing, writing, etc. As a student it might be harder to communicate ideas, or show working” (Scott) and “as it stands now though, you can't assume that every student is going to have the means, facilities, or even technical knowledge to be able to be able to study like this” (Peter). Such comments clearly indicate that there are still hurdles in place preventing the acceptance of web conferences as part of learning for the future with teachers in schools. This is well articulated by Heirdsfield et al., (2011) with the recognition of the one of the hurdles is that staff need more training and support in order to see opportunities to incorporate new and innovative technologies into existing practice.

Conclusions

The use of web conferences as a valuable tool in online teacher education has been demonstrated in numerous studies (den Exter, 2012; Heirdsfield et al, 2011; Reuschle &Loch, 2008) and has been reaffirmed in this study. The comments in regard to the collaboration, interactivity and removal of the feeling of isolation that were made by participants in these earlier studies resonated with comments by students in this study. Comments from participants in Reuschle and Loch (2008) such as “The Elluminate events were a highlight of this course for me. I enjoyed the interaction and hearing the fellow learners' voices. It added a degree of humanness to the virtual environment.” voiced similar views to this study. Terms such as ‘intimacy’, ‘connectedness’ and ‘collaboration’ were frequently used by the students in this research. The reduction of the isolation that is often associated with online learning was identified by Reuschle and Loch (2008) and was a common theme in the responses given in this study. The increased communication and collaboration possible in the web conferences were highlighted with the web conferences lauded as the closest possible replacement for on-campus tutorials. This view was supported by comments expressing the view that ”face to face is probably the best way to study any subject, but this excludes people in remote areas. I believe that the webinar is the next best thing” (Anne). Learning and teaching are changing rapidly and features that are available for web conferences continue to increase. Teachers of the future will need to be prepared to teach in a variety of ways and are likely to include the use of web conferences. With the rate of online education growing much faster than 'bricks and mortar' education (Chau, 2010) it is appropriate to implement and model collaborative tools such as web conferencing in pre-service teaching programs to equip the teachers of the future. Teachers need to be prepared to teach in an ever changing technological landscape and teacher educators need to consider new approaches to online teaching and be given the support to model and manage new and innovative approaches (Downing & Dyment, 2012; Saltmarsh & Sutherland-Smith, 2010). Web conferences are an ideal vehicle to provide the collaborative and interactive tools needed to support current and future teacher educators as they prepare for imminent pedagogical and technological change.

New approaches: Embedding on-line interactive scenarios as core course components for international biosecurity practitioner training

Terry Mark Stewart
Centre for Teaching and Learning (Manawatu)
Massey University

Massey University

Willem D. Vink
EpiCentre, Institute of Veterinary, Animal and Biomedical Sciences
Massey University

Interactive scenarios were used in an on-line international Masters degree programme for veterinary and public health professionals launched in 2010. For two courses in the programme, students were required to play the role of a senior advisor, analyzing data, determine the cause of an unfolding disease outbreak and critiquing recommendations. The scenario was presented in six episodes. Each episode was designed to be completed in one sitting and these also contained the history of previous episodes. On-line forums were used for group activities which included a vote on the diagnosis. Students were also required to give a critique of the diagnosis and solution proposed in the scenario. A student survey rated the use of the scenario-based approach highly with motivation and engagement being the most obvious benefits. This paper illustrates how an interactive scenario can deliver student outcomes when be embedded at the very core of a course.

Keywords: interactive scenarios, case-based learning, scenario-based learning, course design, SBL interactive, biosecurity training, epidemics, health professional training, authentic learning

Introduction

Learners need to see relevance in the tasks they are set. There is general agreement in educational circles that student engagement is enhanced and better learning is accomplished where groups of learners are immersed in authentic, real-world problems (Barnes, Christensen & Hansen, 1994, p. 1-6; Herrington, Reeves & Oliver, 2010, p. 216; Jonassen, Peck & Wilson, 1999, p. 229). One way to facilitate this in an on-line setting is to use interactive scenarios or cases, where students are required to explore, investigate and analyze an unfolding situation (or crisis!). However, it is also recognized that benefits from any "active learning" approach are not automatic, and it is important that such activities are designed carefully, and embedded (and scaffolded) correctly in the context of the course as a whole (Hmelo-Silver, Duncan & Chinn, 2007; Kirschner, Sweller & Clark, 2006). Failure to do this can confuse the student and undermine the learning objectives.

The following case study reports on the design, implementation and evaluation of two sequential courses which had an interactive scenario (or case) at their core. It illustrates how these scenarios, properly embedded and supported as a core component of the course, can interest and motivate students. Furthermore, they can also be used as an engaging platform to facilitate other activities important to the learning outcomes, such as collaboration (groupwork) and report writing.

Background

Recent years have seen a number of human diseases emerge which have their origins in animal populations. Some examples include the SARS virus, HPAU and N1N1 influenza. Furthermore, these global threats often arise in developing countries where limited capacity exists to deal with them. Sophisticated interdisciplinary training is required in disease surveillance, investigation and control, along with institution and policy building. In 2010 Massey University launched a "One Health" for Asia program to strengthen the response to outbreaks of major human and animal infection diseases in three sub-regions of Asia (South Asia, Central Asia and East Asia). Part of this program provides Masters level training of public health doctors and veterinarians. Of the eight papers offered in the two-year Masters programs, seven are taught entirely on-line whilst the eighth is a combination of on-line and regional face-to-face training. The first four courses provide a foundation in epidemiology and are common to both degrees. The remaining four courses address specialised topics related to human or animal health. Each of the eight courses is delivered over a six-week period with a study load of about 20 hours per week, using the Moodle Learning Management System. Intensive student support is provided online, with tutors overseeing groups of students at a ratio of approximately 1:8.

It was decided to use an interactive scenario as a core component in two of the four compulsory courses titled 'Epidemiological Techniques for Disease Investigation' and 'Principles of Disease Control and Management'. The overall purpose of these two courses was to give students the skills to prepare an outbreak investigation plan, manage an epidemiological investigation, develop hypotheses regarding risk factors, recommend control measures and evaluate their success, and communicate the outcomes to different stakeholder groups. Such outcomes fitted well with a scenario or case-based approach. Also, teaching an almost fully on-line Masterate program of eight courses to working professionals in developing countries is a daunting challenge. Notwithstanding potential technology issues, there is a mix of languages, cultures and pre-knowledge. Consequently, it was important to develop lessons that incorporated activities and examples that had current relevance and that engaged and motivated the students.

The outbreak scenario

Description

The scenario was based on an actual disease that emerged in South East Asia during the 1990s, killing both humans and animals. In essence, very early reports of an unfamiliar disease in animals were not investigated thoroughly and were not identified by authorities as being unusual. The early stages of the ensuing outbreak showed a pattern similar to a commonly occurring endemic disease, although some epidemiological evidence did not support this hypothesis. Intensive control measures were implemented, but these failed to contain the disease which spread to become a major epidemic. This example was chosen as it contained the ideal ingredients for an authentic online learning scenario that would address the learning outcomes. These included knowing how to deal with complex epidemiological problems involving humans and animals, compounded by socio-cultural and socio-economic aspects.

Development

Two people were involved in the creation of the interactive scenario. One was the subject expert responsible for developing the activity; the other was the e-learning instructional designer whose main role was to author the scenario. Both were working from different geographical locations.

The scenario was initially "mapped out" using storyboarding techniques at face to face meetings. After the structure of the scenario was agreed on, development of content was facilitated using a scenario schema. The schema was a Microsoft Word document which initially was a template. Specifically it just contained headings laid out sequentially representing specific information and activities students would be exposed to as they progressed through the scenario. Text was often included under these headings which elaborated on the content the scenario authors wanted to put there.

The schema was split into segments. Work on the content then progressed section by section. Each section was initially filled with draft content by the subject expert then provided to the instructional designer by email for comment. The document would then be passed back. It was a collaborative process, and each section of the schema would often pass through several iterations before being finalized. Once it was deemed ready, the content was cut and pasted from the schema to the scenario authoring and delivery tool. The tool of choice was Scenario-Based Learning Interactive (SBLi) (Unversity of Queensland, 2012) an e-learning software package designed for presenting storyboarded scenarios. SBLi gave a structured interface to the scenario, allowing students to always see where they were in the timeline of the case. Furthermore, it facilitated an interactive learning process by integrating narrative, activities, and reference material into one environment.

While the scenario was modelled on the actual sequence of events that unfolded during the outbreak, fictional place names and dates were used to reduce the opportunity for students to identify the cause of the outbreak through Internet searches, and increase the probability that they developed their own hypotheses based on their interpretation of the data with which they were provided.

Pilot

Once developed, a draft scenario was piloted using a group of campus-based Master of Veterinary Science students with similar backgrounds to the students in the 'One Health' Masters degrees. The students were observed as they worked through the scenario, their progress was timed and their experiences recorded. The developers questioned the students on coherence of the interface, ease of navigation and whether the tasks and their purposes were clear.

Some important modifications were made as a consequence of this trial. One major modification was to break the large and complex scenario into a series of separate installments or 'episodes', each of which could be completed in two to four hours. This served to maintain the students' interest in the scenario. It also enabled tighter integration of the scenario into the course, by interspersing the episodes with relevant teaching material and resources in the Moodle environment using a combination of formats including web pages, discussion forums and activities, primarily to facilitate group discussion (Figure 1). Each successive SBLi episode contained all the content of the prior episodes for student review, but excluded the tasks or questions contained in these as they added scaffolding (hence extra work) which was no longer required.

Another finding from the pilot was the necessity of familiarising the students with the SBLi interface and its functionality. Navigation in SBLi was not always intuitive to those familiar with standard web browsers, and certain conventions were used such as color-coding text boxes to represent hints, tasks and navigation instructions. An introductory SBLi training scenario was developed which introduced the interface and conventions used. This introductory "training" episode was worked through prior to commencing with the scenario, to reduce the extraneous cognitive load which would come at the expense of learning (Van Merrienboer, Kirschner & Kester, 2003).

Delivery

In the Moodle course page of the 'Epidemiological Techniques for Disease Investigation' course, each episode of the scenario was prefaced by a static webpage that presented teaching material related to the relevant stage of a disease outbreak investigation (Figure 1). Clicking on the scenario icon launched the scenario in a new browser window.

Working through the scenario
Students were introduced to the crisis in the first episode of the scenario (Figure 2). They subsequently worked through the scenario step by step, as participants or actors in the story. Narrative was written in the second person to enhance engagement. At almost all stages of the scenario, students were required to complete a task to reinforce the learning. This could take the form of selecting options from tick-boxes, developing definitions or conducting analyses as the data became available. Feedback was provided to each question.

Students sequentially worked through the activities which gradually appeared from left to right across the top of the screen. Each activity would include a series of action links which would appear from top to bottom in the left-hand window. As with the activities, these links would not become visible until students had completed the work under the previous one. Resources could also be included from within the scenario. For example, clicking the link in the main page shown in Figure 3 brought up a Microsoft Excel spreadsheet with data that students subsequently used as they were guided through descriptive analyses of the data.

Students worked through the first five episodes of the scenario individually, gathering data about the outbreak, conducting descriptive analyses and interpreting disease spread patterns. Having completed the five episodes, the students were challenged to interpret their findings and develop a hypothesis regarding the cause of the outbreak. Also they were required to summarise their thoughts on the most likely factors causing the disease together with the supporting evidence.

Figure 1. Flowchart showing the staging of the scenario across the two sequential Moodle courses, including the different activity types.

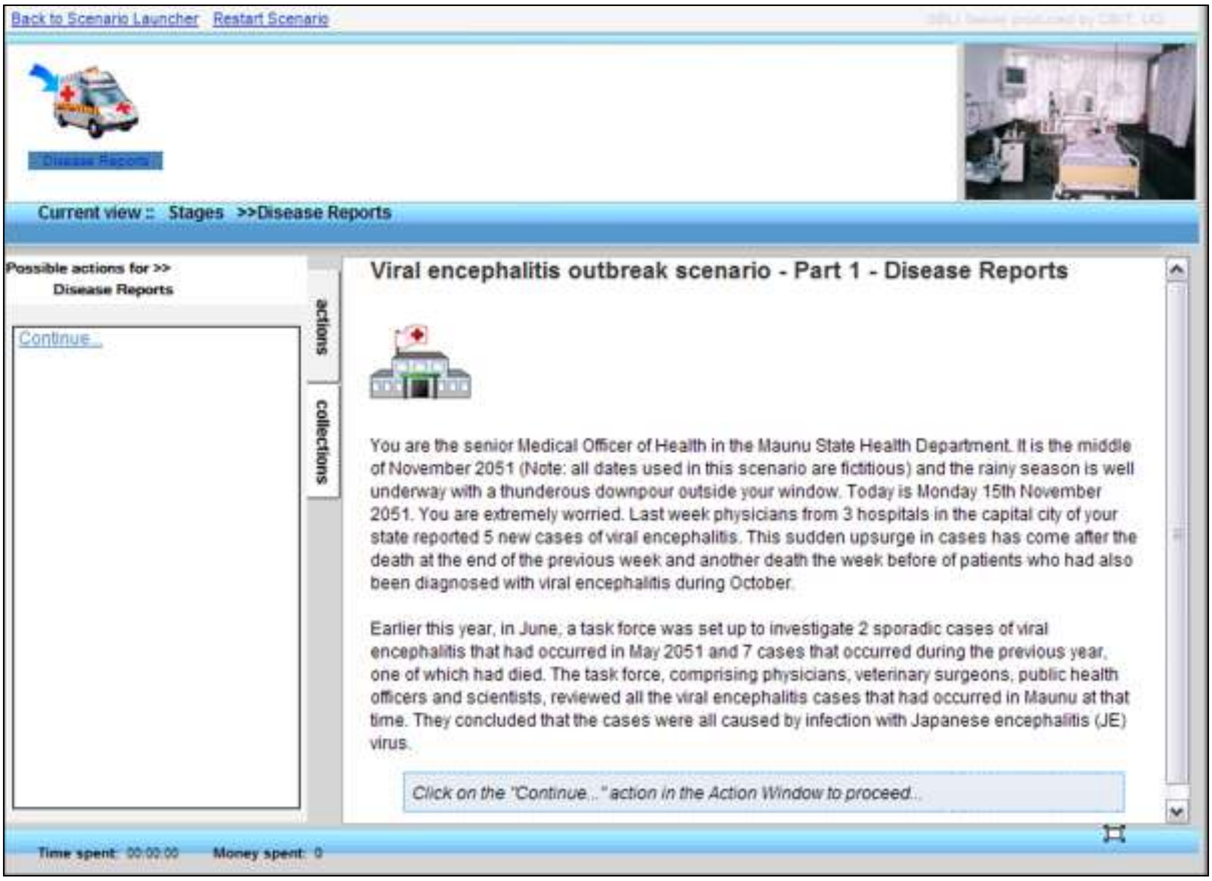

Figure 2. Introducing the scenario in SBLi

Group work

Subsequently, the scenario moved into small group activities for which students were placed into 11 groups of 6 to 7 students, comprising an equal mix of doctors and veterinarians from different countries. The members of the groups were asked to discuss their hypotheses and supporting evidence, and produce a group report. All students were then asked to peer review the other groups' reports and finally to vote on their hypothesis regarding the cause of the outbreak. This task was designed to mimic a situation of an investigation team discussing the results of their investigation and coming to a consensus with respect to their conclusions and recommendations. All discussion amongst group members was via separate group forums within Moodle.

Assessable output: An outbreak report

The final episode in the 'Epidemiological Techniques for Disease Investigation' course provided context and content for the development of skills in communicating the findings of an outbreak investigation to a key decision maker such as the Minister of Health. The students were required to submit an individual outbreak report, which was to clearly communicate a conclusion regarding the cause of the outbreak, support this with appropriate epidemiological evidence, and recommend further investigation and / or control measures.

Carry through to subsequent courses

To assess the effectiveness of the implemented control measures, three additional episodes were integrated into the subsequent course 'Principles of Disease Control and Management' (Figure 1). The emphasis of these episodes was placed more strongly on the affected livestock populations. The final episode presented new evidence showing the consequences of the incorrect diagnosis and inappropriate control measures that resulted in spread of the disease to a new area and development of a major epidemic. The students were given the opportunity to re-evaluate their initial diagnosis in light of this new evidence, and vote again on the group hypotheses developed previously.

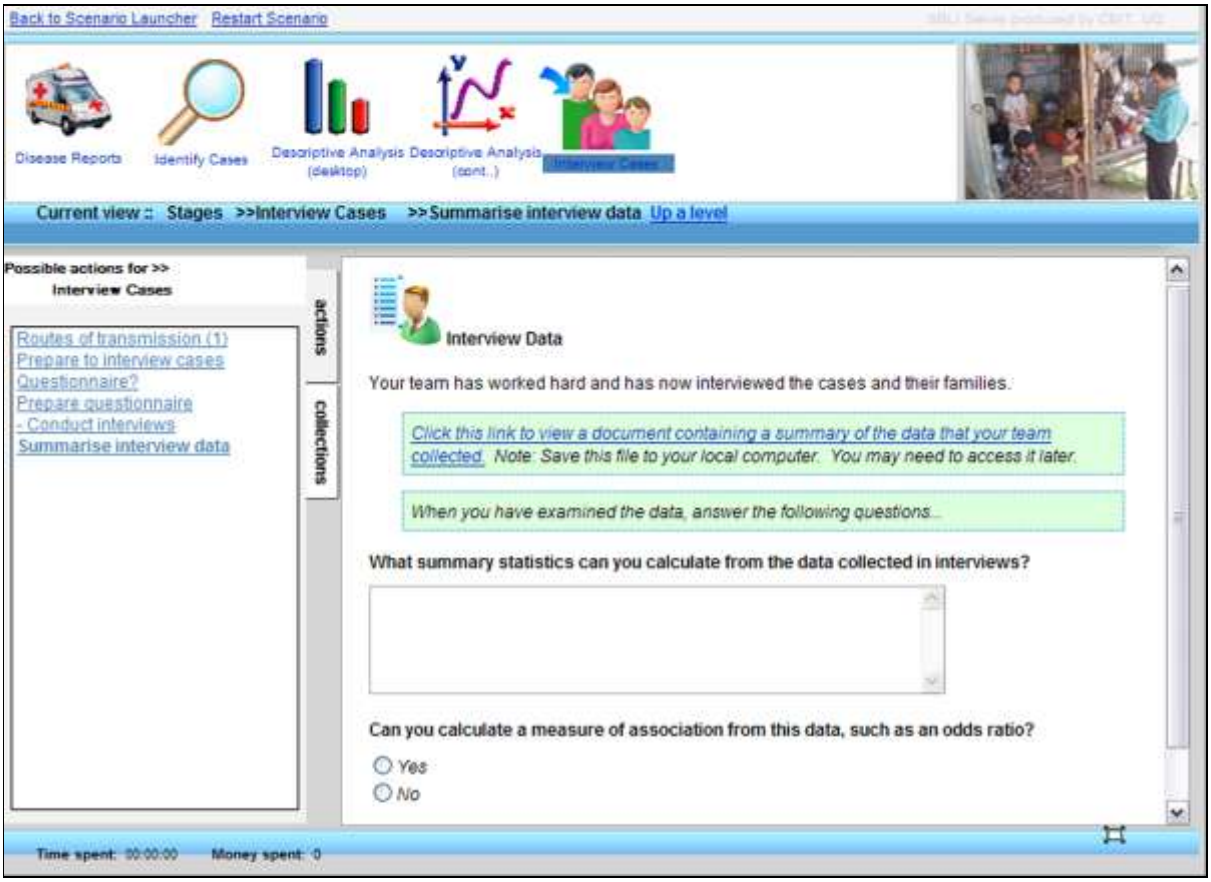

Figure 3. Scenario content screen showing link to data resources and questions

Face to face work
This course incorporated an intensive two-week face-to-face training component. During this workshop, the students were shown a documentary which provided footage of the outbreak, and disclosed its cause. This brought the scenario to life and showed the impact of the outbreak on peoples' lives and livelihoods. It also discussed the mistakes made during the investigation and diagnosis of the cause. It presented the likely involvement of wildlife as the source of infection, bringing the scenario into the full context of the 'One Health' programme.

Later in the face-to-face workshop, the scenario was used during a session on effective management of the media during an outbreak crisis. Student pairs comprising a doctor and a veterinarian were interviewed and asked to prepare a joint press release for the Ministry of Health and the Ministry of Agriculture, providing information about the disease, how people could protect themselves and how spread could be prevented.
In a later course ('Public Policy in the context of Disease Management'), the scenario was revisited and used as a case study to discuss and identify behavioural changes that would assist early detection of a new disease.

Results

In an evaluation questionnaire of the 'Epidemiological Techniques for Disease Investigation' course, students were asked to evaluate the following four aspects of the learning approach used:

1. Embedding the problem-based learning (SBLi scenarios) with the course material (web pages)
2. Using the SBLi interface, and quality of the scenarios
3. Preparing the investigation report
4. Discussing the hypothesis

A total of 46 out of 67 (69%) students completed the course evaluation questionnaire. The majority of respondents found the four aspects of the scenario to be either very effective or quite effective (Figure 4).

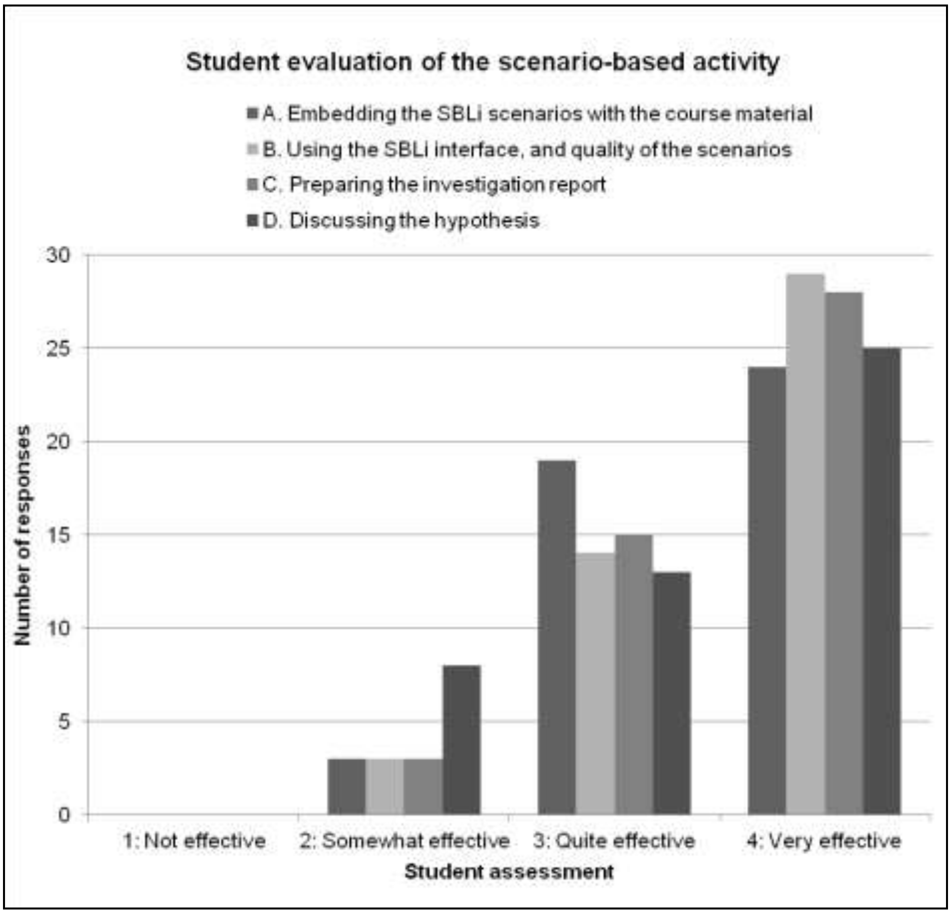

Figure 4. Chart showing student evaluation of the scenario and SBLi. Students were asked for their opinion on the effectiveness of the scenario and SBLi related to presentation of content and facilitation of activities (n=46)

Students were also asked open questions about what they enjoyed most about the course and what they enjoyed least. As these were free-form questions, the results were parsed and categorised into a series of identifiable aspects. Many respondents agglomerated several aspects into one response. Twenty-five respondents (56%) explicitly considered the most enjoyable aspects of the course to be related to the scenario and related activities (Table 1).

Table 1. Responses from the evaluation questionnaire to the open question, 'What did you like most about the course? '. 46/67 (69%) students completed this question. The 25 responses that refer specifically to the interactive scenario are presented in bold font.

Q. What did you like most about the course?	**Number**
SBLi scenario	**16**
SBLi scenario and group work	**6**
Group work	9
Capacity development and the concept note	4
Logical framework analysis	1
SBLi scenario and report writing	**3**
"Activities"	3
Almost all	2
Report writing	1
"We were forced to work"	1
Total responses	**46**

Some reported that almost everything was enjoyable. However, three students cited the scenario-based lessons as being the worst aspects of the course! Four others mentioned that there should be more scenario based lessons in future courses.

Discussion

While it is not possible to quantify how much the interactive scenario contributed to learning per sé, it was clear that a majority of students enjoyed this aspect of the course. This is reflected in 54% of the course evaluation respondents ranking the scenario and its activities as the most enjoyable aspect of the course (Table 1), indicating a high level of satisfaction with this approach to teaching. Motivation and engagement are both important elements for learning (McMillan, 2010, p. 1-13) and it is clear the scenario provided both. This is typified by one student's comment in the feedback which said "[The SBLi scenario]…was really practical, inspiring and interesting! ". The following comments indicate that some students enjoyed the novel teaching method and found it stimulated them to think about the problem: "The scenario was interesting as well as confusing, helping to think more to probe the situation" and, "This is the first time I have encountered scenario based learning and found it very useful as an effective learning tool".

Given students were unfamiliar with SBLi, a walk-through scenario to get the students used to the SBLi interface before the real lesson also proved to be worthwhile. This is reflected in the following student comment: "I was so scared to open SBLi. But once opened - nothing to fear". Navigation through an interactive learning environment can be cognitively challenging and students benefit from prior exposure to it and the conventions used (Liang & Sedig, 2009).

Presenting this large scenario in sequential workable units (i.e. episodes) was decided upon after running the pilot. This change proved to be extremely valuable. It facilitated tight linking of the teaching material in Moodle with relevant episodes of the authentic activity-based scenario in SBLi. Students could complete these episodes at one sitting which assisted focus.

Using a mix of resources and activities in Moodle also contributed to variation. Rolling out the scenario episodes over time meant that students were all more or less at the same place within the scenario, which assisted the tutors in providing support. However, having split the episodes, it was important that students had the ability to revisit earlier parts of the scenario; this was not straightforward, as much of the episode content (when first visited) was bound up in the feedback to questions (some rhetorical) which students needed to answer. The solution to this problem was to preface each scenario episode with a history of those before it, but with the content explicit, which could be revised or skipped depending on the inclination of the student.

Integrating both the scenario narrative and related exercises within SBLi, rather than splitting these between SBLi and Moodle, minimised the "split attention effect", which can arise where students jump between systems to obtain information and to conduct activities using this information. This has been shown to have a detrimental effect on learning by adding extraneous cognitive load (Van Merrienboer & Sweller, 2005). The use of narrative in the scenario, rather than just presenting plain facts, was designed to immerse the student as a participant or actor in the story where events unfolded over time. Hazel (2008, p. 199-213) discusses the importance of narrative in interactive learning environments, where it can build both coherence and context.

It should be mentioned, however, that developing this narrative was quite time-consuming. The story had to have integrity and credibility. It had to "feel" real. The cause of the outbreak was a puzzle and clues to the solution lay scattered throughout the timeline. The skills to produce such work are more akin to storytelling or film and these requirements need to be factored into any design budget using this learning design.

The use of a scenario schema was extremely beneficial to facilitate communication between the subject expert and instructional designer as they crafted content before it was entered into SBLi. Furthermore the schema holds the whole scenario content as a flat file in an easy accessible format. This is valuable in case the scenario (or parts of the scenario) are reused in a different authoring/delivery package . Using scenario schemas is now a standard practice at Massey University for developing SBLi scenarios with a team. (Stewart, 2011; Stewart, Brown & Weatherstone, 2009).

There was considerable value in linking the outbreak investigation scenario with group work, report writing activities and communicating with the media. It reinforces the value of incorporating and embedding interactive scenarios into the core of the course in an integrated way, rather than using them as simply an add-on where their value may not be fully exploited (Gossman, Stewart, Jaspers & Chapman, 2007)

Integrating the scenario into the face-to-face course following the on-line activities provided a very effective way of concluding the scenario on a dramatic note. Students were intrigued to find out from the documentary if they had correctly identified the cause of the outbreak. Furthermore, the documentary brought the scenario to life, showing the impact that the outbreak had on people's lives and livelihoods and discussing some of the controversial issues associated with the management of the outbreak. This provided an excellent segue to wrapping up the scenario with a general discussion of the key issues relating to 'One Health' investigation and management of diseases affecting animals and people and to early detection of emerging diseases.

Conclusion

We believe the integration of the unfolding disease outbreak scenario into the courses described above reflects "Learning for the Future" and adheres to Meyers and Nulty's five curriculum design principles (Meyers & Nulty, 2009). They argue that in order to maximise the quality of student learning outcomes, courses should provide students with teaching and learning materials, tasks and experiences which:

1. are authentic, real-world and relevant;
2. are constructive, sequential and interlinked;
3. require students to use and engage with progressively higher order cognitive processes;
4. are all aligned with each other and the desired learning outcomes; and
5. provide challenge, interest and motivation to learn.

The combination of an on-line scenario-based approach with group work, report writing activities, face-to-face discussion and role play was effective in presenting an immersive learning experience. While most students were unfamiliar with this teaching model (and some were initially apprehensive), the levels of participation and enthusiasm were high. As with any course, there is room for improvement but the student feedback and positive evaluation reflected a high level of satisfaction. The scenario grounded the learning in context and facilitated group work, embodying what Reeves, Herrington & Oliver (2002) defined as "authentic activities".

Acknowledgements

The authors would like to acknowledge the significant help of those who provided details and insights of the real outbreak; assistance with the communication aspects from Lisa Emerson and Margie Comrie; additional instructional design input from Darelle Thomson; and the feedback from the students. In addition, they acknowledge the contributions by the course coordinators and developers, particularly Barry Borman and Jackie Fawcett. This programme is financed by the European Commission's Animal and Human Influenza Facility, the funding of which is managed by the World Bank.

Flex and inflexibility: The impact of real-time collaborative technologies in highly customisable video-linked teaching spaces

Scott Symonds

Mark Brown
National Centre for Teaching & Learning
Massey University

This paper introduces a major investment in 'state of the art' video-linked teaching (VLT) facilities aimed at supporting collaborative teaching and learning across and beyond the campuses of Massey University. It reports how the design and development of the VLT spaces have resulted in unexpected challenges that are occasionally counter to the flexible teaching philosophy that has informed the design of the rooms. Some initial feedback is shared from the early experiences of staff and students, indicating several lessons for other institutions wishing to exploit the potential of VLT and related new 'hybrid' learning spaces. Overall the poster offers a glimpse into an engaging, tactile learning environment which goes beyond traditional video conferencing and highlights some of the pedagogical implications that have arisen through the project pilot phase.

Keywords: Video linked teaching, video conferencing, synchronous, flexible, learning spaces

Background

Massey is New Zealand's largest provider of tertiary level distance education with campuses spread across three North Island locations. The distributed nature of Massey's students and physical infrastructure has provided the impetus behind a rapidly accelerating use of synchronous teaching tools. Until recently, this has mostly taken the form of desktop conferencing applications such as Adobe Connect, Scopia and Skype. Video conference meeting rooms have also been pushed into service as a means of linking simultaneous face-to-face classes on different campuses. Whilst online learning technologies have increasingly blurred the boundaries between modalities, the virtual-physical, distance-internal divides still remain. Video-linked teaching has been envisioned as a means to, as far as is currently possible, remove the barriers of physical teaching space in order to bring together classes of distributed learners.

The VLT project mirrors a sector-wide focus on re-imagining 21st century learning spaces in order to realise "the power of *built pedagogy*" (Oblinger 2006). Traditional teaching facilities continue to be employed across the tertiary sector, many of which encourage transmissional or linear approaches to teaching and learning. It has been suggested that "pedagogical innovation demands a space that enables exploration by both teacher and student" (Neill & Etheridge 2008) and it was with this ethos of innovative teaching and active learning that three hi-tech, flexibly designed VLT spaces were proposed. Envisioned as 'nodes' that would enable distributed learners and teachers to come together in highly interactive, media-rich, real-time collaborative environments, a pilot project was given the go ahead and facilities that support classes of up to 50 students were constructed through the first half of 2012 in Auckland and Palmerston North. Several 'ad hoc' video conferencing rooms have been adapted as linked facilities on the Wellington campus making it possible to link all 3 campuses. 3 classes were taught within the rooms through semester 1 2012.

Spatial design and effect on teaching

VLT spaces have been designed for use with modular, mobile furniture and enable classes to be set up in a wide variety of formats. The amount and flexibility of cameras, displays and inputs, as well as whole-room audio coverage mean that teaching staff have a staggering number of options to consider prior to teaching. This puts a great emphasis not only on technical knowledge of the spaces, but on pedagogical approaches and how these are integrated with the technology to facilitate effective classes. Initial observations indicate that the flexible format of the rooms offers huge scope prior to classes but can be disruptive and disorientating for students if altered mid-class. Prior planning and ‘scripting’, as well as on-demand technical and academic support have proven to help mitigate these issues. Students have also reported that familiarity of room layout plays a major part in their ability to engage successfully in VLT classes; that knowing where information and camera feeds will appear is essential to the navigation of their learning environment and ultimately to their learning experience. Repeated manipulation of a class’s learning environment is not necessarily desirable or effective.

Academic development

Academic support was built in to the project as part of the initial funding application and has proven to be of value through both the design and implementation phases of the pilot. A series of on demand web-based/mobile resources, planning materials and guides have been produced to support academic staff. These resources along with one-to-one consultations, monthly hands-on professional development sessions and heuristic opportunities for academics to review and re-imagine their VLT classes, are enabling teaching staff to more fully exploit the interactive and collaborative potential that the rooms offer (Steel & Andrews 2012).

Teaching consultants worked closely with academic staff to gather lesson plans, layout diagrams and feedback from semester 1 classes. This information informed the design of a series of ‘presets’ that can be used as one-touch starting points for the setup of classes. Room planning documentation, preset guides and ‘visual planners’ have also proved valuable aids in the design of VLT lessons.

Initial observations

The three pilot classes were all team taught, with academic staff facilitating in each location. Students acknowledge the benefit of multiple perspectives and the variety of expertise this has brought to their classes, whilst staff have welcomed the opportunity to ‘team teach’ and co-develop their papers. Students are wary of the potential for ‘remote’ teaching, but enjoyed the increased intimacy that the rooms have brought to their learning experience and have pointed out the contrast to other classes held in more ‘authoritarian’ teaching spaces. Students appreciate the opportunity to develop closer relationships with their teachers, the subject matter and the learning process itself.

Staff and students alike require extended initiation to these new spaces, with students citing familiarity and comfort with the technology as major factors in their ability to successfully learn within the VLT rooms. There appear to be some concerns from staff and students about the potential for sensory overload if too many data sources, cameras and other locations are introduced. Anecdotal evidence suggests that a ‘busy’ environment is more tiring and leads to shorter periods of engagement. The effect of a prolonged and overwhelming sensory barrage on working memory and how this might affect cognitive load is as yet unknown, and this is an area that will require further study if these teaching spaces are to fully benefit, not hinder the learning experience.

What next?

A formal evaluation of the semester 1 classes is in progress. Student focus group interviews, teacher and academic support staff interviews, and a quantitative survey have been conducted. Data analysis is underway and it is expected that a pilot phase evaluation report will be available before the end of the year. Evaluation will be ongoing, with more focused research planned once a broader evaluation has been conducted.

Proposals to extend the pilot and build a third VLT facility on Massey’s Wellington campus are underway. Integration of existing synchronous and asynchronous rich media, collaborative technologies (Adobe Connect, Mediasite) are also being investigated to allow distance students to participate in VLT classes.

Massey University

Mark Brown
National Centre for Teaching and Learning
Massey University

A major 'state-of-the-art' video-linked teaching (VLT) project at Massey University encompasses the development of two purpose-designed rooms to support real-time teaching across two campuses. The intention is for these rooms to be used to establish a strong presence and sense of connection between teachers and students located at each site, offering the ability to teach two (or more) physically distanced classes synchronously with a focus on rich interaction and collaboration. This paper reports on the initial findings of a research project investigating how the VLT rooms have been used during the Semester 1, 2012 experimental pilot phase. It shares some of the experiences of the students and teachers involved and identifies a number of benefits and challenges of using such VLT rooms from pedagogical, physical space and technological perspectives. Finally, the paper reports how the preliminary findings from this research are informing the ongoing use of the facilities as well as the design and implementation of a wider range of teaching and learning spaces.

Keywords: Video linked teaching, video conferencing, synchronous, flexible, learning spaces

Background

Massey University's physical infrastructure is distributed across the North Island of New Zealand with three main locations in Albany (Auckland), Manawatu and Wellington. The distributed nature of Massey's campuses has meant that video conferencing (VC), amongst other methods, has become a key component in communication between departments and colleagues based on different sites. The relative availability of VC facilities for administrative purposes has encouraged staff within several disciplines to experiment with the service for teaching and learning. The College of Sciences, for example, has used VC to link classrooms in New Zealand and Singapore, as well as between campuses, for several years. The College of Business, and College of Humanities and Social Sciences have also used it for small group intercampus teaching, particularly at advanced undergraduate and postgraduate levels. An increased level of interest from all colleges in providing connected classes to larger groups of students across a wider range of courses was the major driver in the development of Massey's video-linked teaching project.

> Our strategy is to facilitate the implementation of [video-linked teaching] to enable collaborative partnerships by removing distance as a consideration from everyday activity (Tate, 2011, p. 4).

Institutional objectives of ongoing sustainability of multi-campus courses and increased intercampus connectivity encouraged the project to really explore "the power of *built pedagogy*" (Oblinger, 2006, p. 1.1) in the design and realisation of these teaching spaces (Hunt, Huijser, & Sankey, 2012; Keppell & Riddle, 2012; Neill & Etheridge, 2008). The project mirrors sector-wide growth in the use of real-time collaborative technologies (Bower, Kennedy, Dalgarno, & Lee, 2011). It has been suggested that "pedagogical innovation demands a space that enables exploration by both teacher and student" (Neill & Etheridge, 2008, p. 47) and this ethos of innovative teaching and active learning has underpinned the entire development process of VLT.

Throughout 2011, rooms were identified on each campus that would be suitable for the intended brief of delivering interactive video-linked classes for up to 50 students. Extended consultation with reference groups consisting of academic end-users, IT technical and support staff, and teaching consultants guided the design of VLT spaces. Three of the most important requirements consistently called for from the academic reference group were: reliability; availability of technical and teaching support; and usability. These became the 'pillars' of the project and to a large extent mediated other factors such as feature set and expense. When it became clear that budget constraints would significantly compromise the design and functionality of a three room build, a decision was made to construct just two spaces on the Albany and Manawatu campuses with an eye to adding a third room in Wellington at a later date. Existing VC infrastructure on the Wellington campus were used as part of the pilot to allow for three-way classes.

The consultation process established technical and pedagogical objectives for VLT classrooms (Tate, 2012). One of the primary technical goals was the creation of as seamless a connection between locations as possible. Clarity of audio and video, large displays to give remote participants more presence and décor intended to give the impression of linked classes being virtual extensions of one another were given high priority (see Figure 1). From a pedagogical perspective, the rooms needed to be flexible enough to accommodate a wide range of active approaches to teaching and learning. Furniture, multiple cameras, a variety of digital input sources and the ability for staff to easily manipulate these components were considered essential for creating an environment suitable for the delivery of rich, interactive classes across a video-link.

Construction began in late 2011 with a budget of almost NZ $1 million and continued following Prince 2 (Projects IN Controlled Environments) process-based project methodology through the experimental pilot phase in Semester 1, 2012.

Figure 1: VLT room, Turitea campus, Manawatu

Experimental pilot phase: Semester 1, 2012

A small group consisting of three undergraduate cohorts of Massey University students along with their lecturers participated in the experimental pilot phase of the VLT project:

- Course A: Taught weekly between the Manawatu VLT room and a standard video conferencing room in Wellington (3 lecturers, approximately 20 students)
- Course B: Taught weekly between the Manawatu and Albany VLT rooms (2 lecturers, approximately 15 students)
- Course C: Taught weekly between the Manawatu and Albany VLT rooms (2 lecturers, approximately 30 students)

Teaching usage for the semester totalled 66 hours across 25 live classes. It should be noted that construction and testing was still happening around scheduled classes, and several components of the final build such as interactive whiteboards, document cameras and room presets were not available. Course A was also constricted by the lack of a VLT facility in Wellington, requiring a simplified connection via a standard VC facility.

The project had technical and teaching support funding built-in and this proved to be invaluable through what had the potential to be a very trying semester of teaching in untested and incomplete facilities. IT technical support was on-hand to assist with set up prior to the start of a class and remained on-site for the duration of classes to ensure a swift response should any technical issues arise. Despite the unfinished nature of the rooms during the pilot semester not one dropout of connection occurred during classes. The conferencing technology that the rooms are based on has continued to be a solid platform and inspires confidence in those that use it.

Academic support has proven to be of value through both the design and implementation phases of the pilot. A teaching consultant assigned to the project has been involved in assisting staff in the design of VLT classes, as well as liaising with technical staff on the implementation of user presets and evaluating the technical build’s application. Presets were based on observations of classes, lecturer feedback and a broader knowledge of the requirements that different teaching styles bring to the layout of a classroom. They enable teachers to tap a single button to call up layouts for specific teaching styles. Presets can be further customised and fine-tuned.

An academic development model proposed by Steel and Andrews (2012) for technology-enriched learning spaces has influenced the ongoing teaching support that is being provided to VLT users. On-demand web-based and mobile resources, planning materials and guides have been produced (see Figure 2). These resources, along with one-to-one consultations, monthly hands-on professional development sessions and heuristic opportunities for academics to review and re-imagine their VLT classes, will enable teaching staff to more fully exploit the interactive and collaborative potential that the rooms offer. Pre-set guides, room planning documentation and ‘visual planners’ have also proved valuable aids in the design of VLT lessons.

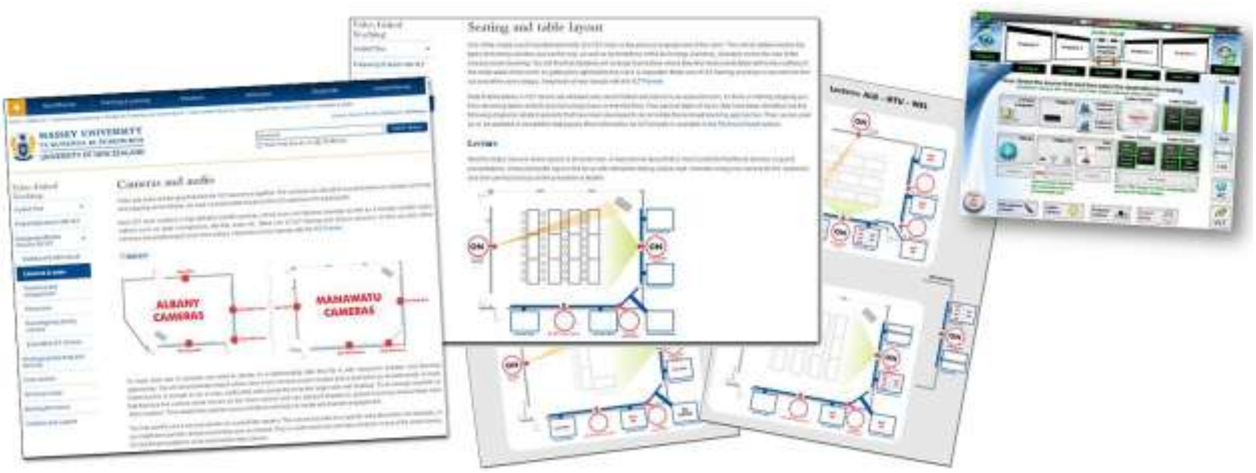

Figure 2: VLT support materials

Initial results

A formal evaluation of the Semester 1 pilot was undertaken, utilising a mixed methods approach. Ethical approval for the evaluation was obtained from the Massey University Human Ethics Committee. Quantitative data from an anonymous student questionnaire were collected alongside in-depth qualitative data gathered through student focus groups and staff interviews, including the lecturers and teaching consultant involved in the experimental pilot phase. Findings presented here draw on student questionnaire data and staff interview data that were collected after the completion of the semester. The questionnaire asked students to rate the importance of multiple factors relating to technical considerations, physical considerations and those related to teaching and learning. While the survey evaluation is based on a relatively small sample of students (n=17) with a response rate close to 30%, the data collected (coupled with insights from staff) provide some useful feedback on the initial implementation and use of VLT at Massey. The results are presented below.

Table 1: Which paper were you studying in semester 1?

Course A	35%
Course B	18%
Course C	47%

Table 1 reports the response rate from each of the three experimental courses. The majority of the respondents (47%) were from Course C, taught between the Manawatu and Albany campuses.

Table 2: How would you rate yourself as a technology user?

Very inexperienced	12%
Inexperienced	0%
Neither experienced nor inexperienced	23%
Experienced	47%
Very experienced	18%

The level of experience as a technology user is reported in Table 2. The majority of students (65%) self-reported that they were experienced or very experienced at using technology.

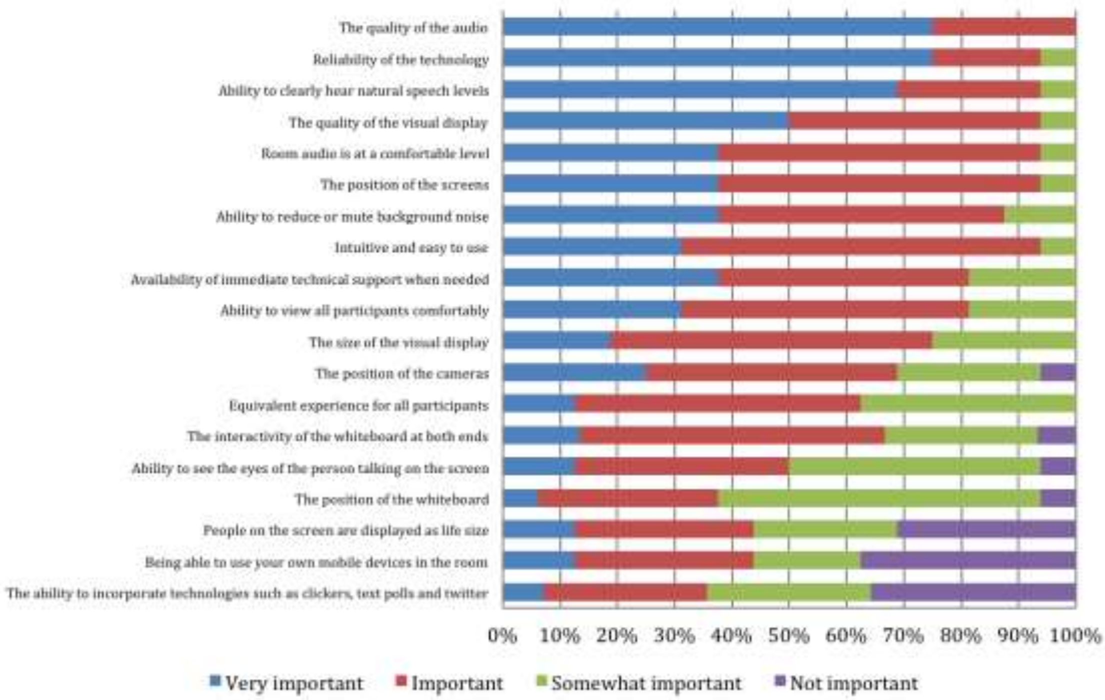

Figure 3: How important do you consider the following technical considerations?

Figure 3 reports a range of technical considerations students perceived as important in the effective use of the rooms. Notably, the most important features were the quality of the audio and reliability of the technology. The importance placed on these technical considerations was echoed in comments made by teaching and support staff as the following comments indicate:

> … you didn't get that delay that you get on the video conference and it's much more real time and you can hear everything well and … I think that worked really well for us. (Course A, Lecturer3)
>
> I mean obviously the goal is to make it as user friendly as possible so that, you know, staff can come in and be able to operate the room without having to have technical support there, but at the moment it's, it's at such a stage, you know, it's at a trial stage and, … it was reassuring just to know that there's that support because you've got students turning up, they're expecting to have a

class and it doesn't look good, it looks pretty unprofessional when there's all of these problems that crop up instead, not that there were any problems particularly. (Course A, Lecturer2)

And make sure you've got the technical sort of support there backing it up to make it successful otherwise there would be lots of wasted time, down time for students, breaks in their learning and you know, I don't think it would work at all. (Teaching Consultant)

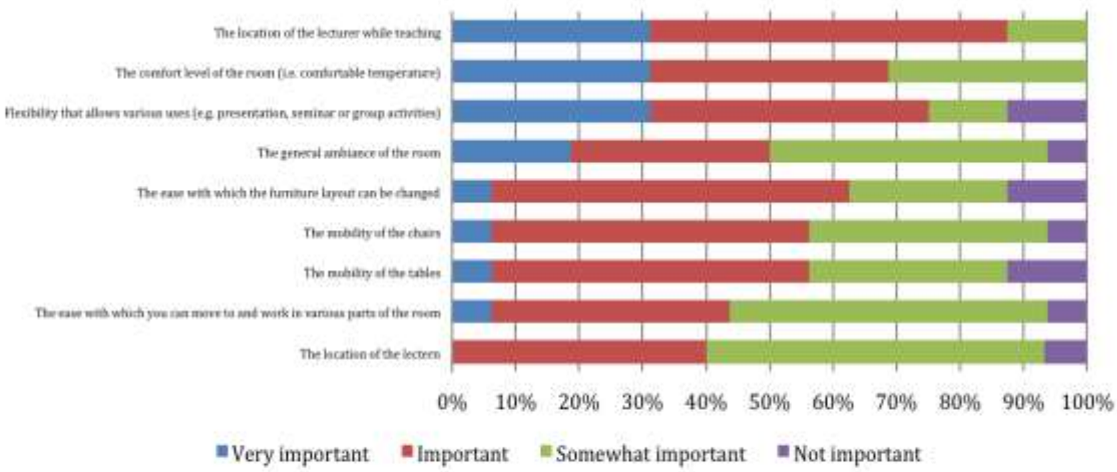

Figure 4: How important do you consider the following physical considerations?

Figure 4 presents the relative perceived importance of different physical considerations. It shows that the locality of the teacher was rated as the most important consideration over and above the comfort level and mobility of the furniture. Staff were also aware of the importance of where they placed themselves when teaching as the following comments demonstrate:

… the teaching spot is quite decentred, it moved elsewhere, and that's what creates a dynamic VLT room … it becomes far more fluid in the VLT space. (Course C, Lecturer1).

You've got to be aware; you have to … you have to keep thinking, oh no I really need to be looking at Albany as well. (Course B, Lecturer)

And where to stand and we'd figured out that we sort of stand on the side and sort of, then we can see both, look at both the screens, it depended on which screen was up too, in the VLT, so if you had to big screen up … on the side wall you tended to look to the side wall because it was a bigger screen, it showed more of the class. But that wasn't where they actually were, you had to turn and face the back wall to speak to the students that were in [the other room]. (Course A, Lecturer2)

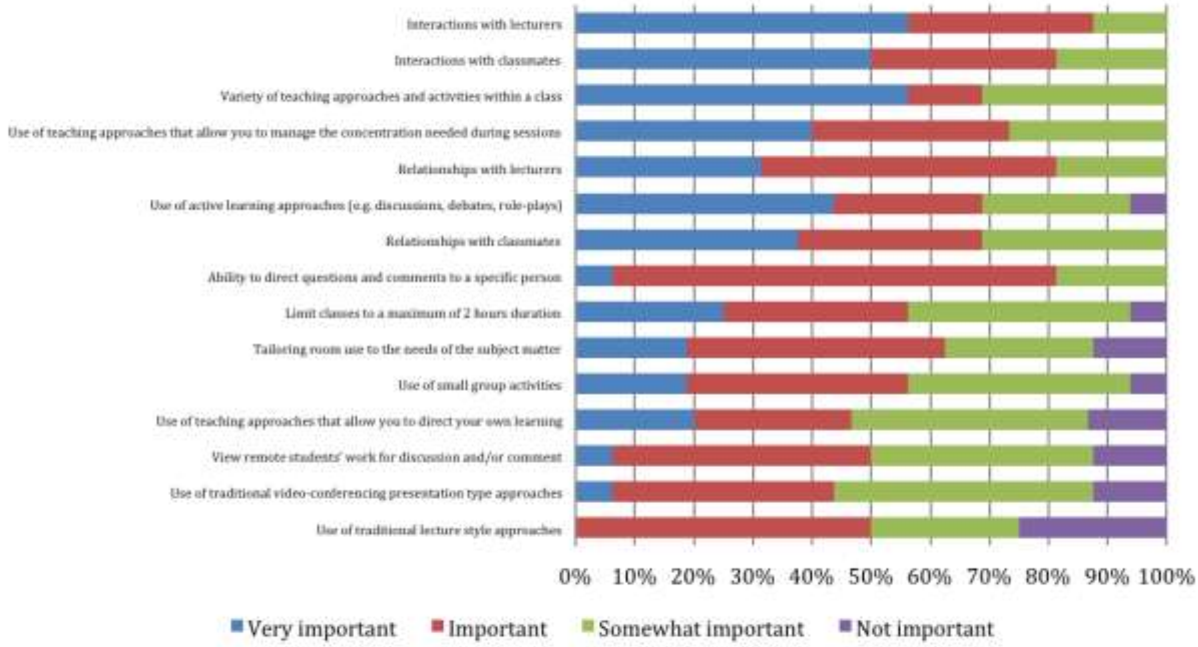

Figure 5: How important do you consider the following teaching and learning considerations?

The relative importance of a number of teaching and learning considerations from students' perspectives are reported in Figure 5. The interactivity of the VLT rooms coupled with the use of a variety of teaching approaches were perceived to be the most important considerations. Staff also spoke of the importance of interaction and teaching approaches that supported this:

> And then the other thing is we were able to use it for group work so one of the speakers we had did the presentation and then in each of the rooms they did group work around what they had done and then the other thing that we have been doing is doing mock presentations because the students have to do their final presentations in a couple of weeks and so they've been able to present to a wider group and that's been good as well. So it's not, it's not a stand and deliver content type lecture. (Course A, Lecturer3)
>
> … it was important to get interaction and discussion going… it was really, really important. (Course B, Lecturer)
>
> [What] Lecturer2 and I realised very early on was that him and me were really important in, in trying to model the interaction in the room … and the more that we could move the kind of locus of activity backwards and forwards between us, the more we could animate the whole room as a single room. (Course C, Lecturer1).

Discussion

It needs to be noted that all three pilot classes were team taught, with academic staff facilitating in each location for the majority of sessions. This approach is not necessarily a model for future use of VLT and some classes may well 'rotate' the physical location of a single teacher through co-taught courses or utilise tutors to facilitate remote locations. Focus group feedback indicates that students are wary of the potential for 'remote' teaching, but enjoy the increased intimacy that the rooms have brought to their learning experience and have pointed out the contrast to other classes held in more 'authoritarian' teaching spaces. Students appreciate the opportunity to develop closer relationships with their teachers, the subject matter and the learning process itself. With these general observations in mind, the following section reflects on the findings in terms of technology, physical space and teaching and learning considerations.

Technology considerations

The overwhelming presence of technology is the first thing that confronts participants in VLT classes. Student survey responses showed a very heavy emphasis on the audio capabilities of the rooms, with four out of the top seven technical considerations being audio-based (quality of audio, ability to hear natural speech levels, room audio at comfortable level, ability to reduce or mute background noise) compared to only two visual concerns (quality of the visual display, position of displays). The importance of high quality audio was also highlighted by staff teaching these courses. These findings were perhaps surprising given the visual nature of the rooms, with each containing five displays and four cameras. One of the major technical goals for the rooms based on user-group consultations was to create as much of a 'physical' presence for virtual/remote participants as possible. This was achieved through creating an 'audience' wall in each room with two large (3m) displays designed to project participants as close to life-size as possible. The student response to this was rather mixed, with over 50% of students responding that displaying life-size participants is only somewhat important or not important. This could signal that the audio qualities of the rooms require more work, but on the basis of these data the visual connection with staff and peers is of much less importance than the ability to hear and speak to them clearly.

Furthermore, students showed a relative lack of interest in using technology such as clickers and mobile devices within VLT classrooms, with over 60% saying this was only somewhat or not important. Along with the emphasis on audio qualities of the rooms, this finding would perhaps suggest that students see these spaces as more suited to conversational and discursive teaching approaches.

Physical considerations

Student responses to the physical aspects of VLT rooms demonstrate the importance they place on their teachers. The overwhelming consideration for students (almost 90% important or very important) was the location of lecturers whilst teaching in the VLT rooms. This point captures the criticality of lecturers staying 'in shot' and in a position where all participants in class feel as though they are being addressed equally. Feedback from staff indicates they, too, were aware of the importance of where they stood and how this could change the learning experience for students, particularly in the other room. Switching position mid-class has proven to fundamentally alter the dynamics of a class, with drops in student engagement in one or several locations noted by teaching staff. It is interesting to note the relative lack of importance ascribed to the visual display mentioned above when compared with this finding, which seems to suggest that certain visual aspects are important (i.e. clear and direct view of the teacher), albeit indirectly.

Flexibility that allows for various teaching activities was also highly rated, but it is notable that students did not really link the mobility of furniture, or indeed themselves, with this statement. Lecturers have reported how the flexible physical nature of the rooms (space, furniture, displays) seems to disappear once a video-link is established and classes begin. Moving students and furniture around rooms during class requires repositioning of cameras, the tweaking of VC data sources (in the case of Course A) and the shifting of content on displays. It is disruptive and potentially counter-productive, increasing the potential for technical problems. Although flexibility of the physical space and furniture was considered a key component in the design and implementation of the rooms, VC technology (on the Wellington campus) has impacted upon this flexibility. Student responses may reflect the way staff have tended to 'set and forget' the physical space to mitigate these issues.

The issue of comfort level can mostly be explained by the lack of air conditioning in the Manawatu VLT room and is something that is currently being addressed. Temperature and lack of airflow was noticeable throughout the semester and significantly impacted student engagement towards the end of classes. Air conditioning is now considered an essential requirement of VLT rooms, which was originally beyond the initial budget.

Teaching and learning considerations

It is perhaps unsurprising that students' most important considerations were about interaction, as this is what the spaces have been designed to facilitate. Interaction with lecturers (almost 90% important or very important) topped the responses to this question, closely followed by interaction with classmates. It clearly demonstrates the need for teaching staff to devote plenty of time to student discussion and questions, and to make the most of the huge potential the rooms offer in this regard. There are important space and timetabling implications in terms of which courses and lecturers are allocated access to the facilities in the future, as the rooms were explicitly designed to avoid the problem of teachers using VC for passive forms of teaching and learning.

Students have also highlighted the importance of a variety of teaching approaches and activities. Consistent with the original goals of the project, they do not want to be talked at: students want interactive, engaging classes. Traditional lecture-style approaches and presentations are of much less importance to participants, and on the basis of these findings they do not rate highly with students. Interviews with staff also support these views highlighting that interaction is very important and that the VLT spaces are not well suited to a stand and deliver lecture-type approach.

Conclusion

In conclusion, the technical and physical flexibility of these spaces offer staff a multitude of parameters that need to be selected prior to teaching. One of the emergent findings is that the technical knowledge required by lecturers to run successful VLT classes is largely overshadowed by the pedagogical skills and lesson planning that staff need to develop. The technical design of the rooms, one-touch user presets and presence of IT technical support has helped to make VLT a relatively user-friendly experience. Initial findings suggest that the onus has now been put on to lecturers to develop suitable teaching methodologies and to employ them effectively in these technology immersive classrooms.

A second emergent point (from the wider study) is that supporting academic staff through this development process will be important to the ongoing success and viability of the technology from a pedagogical perspective. Professional development sessions offering hands-on experience are being offered monthly, and are designed to encourage staff to re-think and adapt their teaching methodologies for truly interactive forms of learning.

Final analysis of qualitative data from the Semester 1 pilot is currently underway, with a full report due before the end of the year. It is anticipated that survey feedback from students will continue to be collected over the coming year in order to form a more complete picture of the student perspective of learning in these spaces and to inform the ongoing technical and teaching development for VLT.

Finally, a positive and consistent theme that runs through the questionnaire data is the value students place on their teachers and their interactions with them. They enjoy being engaged in their learning and having the opportunity to develop closer relationships with academic staff. In this sense, the VLT rooms can be used to ‘flip’ the traditional classroom, although the effectiveness of this depends on a number of factors which include technology, physical space and pedagogical considerations. That said, the VLT project at Massey was designed to bridge the physical space between groups of students across campuses and so far they appear to be successful in breaking down the metaphorical distance between lecturers and students. There is emerging evidence to suggest that when used appropriately, VLT is paving the way for less transmissive teaching approaches and a more interactive and egalitarian classroom.

Improving learners’ self-efficacy in a learner-controlled online learning environment: a correlational study

Massey University

Online learning is gradually being adopted by higher institutes and becoming much more common in higher education worldwide, but some learners still find it challenging. Though they are familiar with computer and technology usage, they are still uncertain of their ability to perform well in online classes. A review of studies focused on how these learners gain more confidence and success shows a link between self-efficacy and learners’ outcomes. Efficacious learners tend to adapt and cope well when faced with obstacles. Moreover, learners who were given control over their learning environment performed better, were more satisfied, and had higher self-efficacy than control groups. It is theorised that embedding learner control into online learning programmes might help inefficacious learners gain more self-efficacy but few studies have investigated this relationship in the real online class setting. Therefore, this study in progress is an attempt to fill in this research gap.

Keywords: Learner control, online learning, self-efficacy, online learner

Research background

Many tertiary institutes now perceive online learning as an educational trend for the future. Online learning is cost effective and can reach more learners. In some sense, it is seen as more creative ways in teaching as well as a sustainable way for learning. Though many studies report success stories of online learning in terms of retention and effectiveness (e.g., Means, Toyama, Murphy, Bakia, & Jones, 2009), findings still show online learners have difficulties in dealing with their learning environment (Cavanaugh, 2005; Cook & Jenkins, 2010; Levy, 2007). Despite using computers and technology in their daily life, they might feel less confident about enrolling in online classes, especially at the tertiary level. They might not have enough of the necessary learning and technology skills for the combination of university and online learning such as skills to compose essays, prepare presentations, analyse data, and do research work (Kennedy, Judd, Churchward, Gray, & Krause, 2008; Mandernach, Donnelli, & Dailey-Hebert, 2006; Ratliff, 2009). Many students still find it hard to adapt and perform well in university online classes because of the demands and stress of the transition from secondary schools to tertiary education. Some students struggle to cope with the complexity of an online environment and often have doubts about their learning performance (Saadé & Kira, 2009). Thus, more technical and psychological support is often needed for online students.

Self-efficacy in online learning environment

In online learning, self-efficacy is considered to be a key psychological contributing factor to students’ success (Pajares, 1996) because it can alter students’ perceptions of their learning environment (Multon, Brown, & Lent, 1991). Consequently, students might perceive their learning environments either positively or negatively. Self-efficacy is not only a good predictor of learners’ academic outcomes but it helps learners well adjust and handle with the unfamiliar learning environment (Alivernini & Lucidi, 2011), even when they have little prior online experience (Swan, 2004).

According to Bandura’s self-efficacy theory, *self-efficacy* is defined as “beliefs in one’s capabilities to organize and execute the courses of action required to produce given attainments” (Bandura, 1997, p. 3). It is a judgment of confidence about the performance of a specific task (Lorsbach & Jinks, 1999). Self-efficacy is not the same as ability or motivation, but they are strongly related (Chowdhury & Shahabuddin, 2007; Vancouver & Kendall, 2006). Indeed, self-efficacy is the personal determination of one's own ability to deal with a certain task. Notably, this determination is not based entirely on actual past experience or existing ability and skills but also on students' perceptions of their own knowledge and ability relative to the task or situation (DeTure, 2004). Self-efficacy is specific to the context of a situation but, once established, is generalized to other situations with the strongest effect taking place in activities that are closest to those in which self-efficacy has been improved. Therefore ensuring that online learners develop self-efficacy within a course means that they should continue to be successful online learners into the future.

Aligned to Bandura's sources of efficacy information (1977), self-efficacy in online contexts is influenced by previous success with online learning systems, online learning technology anxiety, instructor feedback and pre-course training, the factors enactive mastery experience, social persuasion, and affective states (Bates & Khasawheh, 2007). In addition, self-efficacy can be improved by giving learners' control over their learning environment (Lawless & Brown, 1997; Luskin & Hirsen, 2010). Thus, an online course embedded with learner control should help support and enhance learners' efficacy.

The concept of learner control

The concept of *learner control* was firstly introduced by Mager and his colleagues to technology-assisted instruction (1961; 1963; 1962) as a way to improve learning performance. Later on, the concept was applied to distance and online learning by many theorists in this field (Candy, 1991; Dron, 2006; M. Moore, 1997; M. G. Moore, 1973). Learner control can differ depending on the technique used and background theory applied since it is multidimensional (DeRouin, Fritzsche, & Salas, 2005). In general, learner control is the extent to which students can choose what, when, where, and how to learn (Kraiger & Jerden, 2007).

Previous studies have shown that the sense of control students have gained while interacting with instructional media and content can turn into satisfaction, enjoyment, and confidence (Luskin & Hirsen, 2010). Research also found that high levels of learner control can improve students' performance (e.g., Chou & Liu, 2005) because students are engaged in greater levels of interaction. These interactions, especially with their classmates and instructors, can make students feel more efficacious through the activities they and their classmates have accomplished, along with the feedback they receive from peers and instructors and emotional states such as satisfaction and a sense of belonging (Piccoli, Ahmad, & Ives, 2001).

However the effects of learner-controlled online environments on students' self-efficacy are not consistent. On the one hand, findings show no differences in students' self-efficacy between non-interactive multimedia and interactive multimedia classes. For example, Maag (2004) found that students in an interactive multimedia online lesson showed no knowledge and self-efficacy gain compared to the control group but they were more satisfied with the interactive tools.

On the other hand, other research has reported an improvement of students' self-efficacy in learner-controlled online environments. Ebner and Holzinger (2007), for instance, found that games enhanced learning, motivation and self-efficacy with a factor called joy. Likewise, Chang and Ho (2009) found that students with the learner control version had higher test scores and self-efficacy levels than those in the programme-controlled version. In the same way, Jaffe's findings (1997) showed that a greater degree of interaction increased students' self-efficacy. However, these effects were not significantly different. This discrepancy in findings may occur because the online learning environment is complex, and the increase of students' self-efficacy can be caused or influenced by many factors other than levels of learner control. Nevertheless self-efficacy is an important factor that teachers can encourage in sustaining students' participation and effort throughout their study.

This study and its implication

As an attempt to fill this research gap, this study in progress centres the attention on the link between learner control, self-efficacy, and other factors such as previous experience in online learning programme and computer skills. In addition, literature in this area shows a few studies that have investigated experiencing levels of learner control in a real online class setting (Jaffe, 1997). Most learner control research has compared outcomes between learner control embedded in web-based learning and those in traditional learning environments (e.g., Chang & Ho, 2009; Chou & Liu, 2005). Therefore, this study focuses on learners in the formal setting of online learning programmes designed to encourage learner control in higher educational institutions.

Building on previous research this study uses a quantitative approach framed by Bandura's self-efficacy theory (1977). The population frame is online learners in an online programme at a tertiary institution in New Zealand.

The purposive sample group is learners in an online programme where levels of learner control were embedded within the course design which learners are encouraged to do a group project in their own ways or they are allowed to complete different tasks choosing their own order within a flexible time frame. To measure learners' perceived confidence toward their online learning programme, the self-efficacy scales are constructed, piloted and validated. Hypothetically, if the correlation between learner control and learners' self-efficacy does exist, learners who are studying in high learner-controlled online programme should have high self-efficacy toward their learning environment.

The questionnaire was constructed by items generated from the reviewed literature and previous validated tools. After reviewed by scholars and experts in the fields, the initial questionnaire comprised four sections: (1) demographic data, (2) a self-report of learners' computer skills, previous online learning experience, and experience with learner control, (3) an online learning self-efficacy scale (OLSE), and (4) open-ended questions for qualitative data.

Then, a pilot study was conducted to test validity of the research instrument and to establish preliminary findings. Thirty-two students, seven males and 22 females, participated in this online survey. About 75% of participants were 25 to 45 years old. About 80% had some to a lot of online learning experience. Seventy-five percent reported themselves having intermediate computer skills, and the rest were advanced users.

The preliminary findings showed a positive relationship between learner control and online self-efficacy. Pearson's product-moment correlation coefficient was calculated r (32) =0.393 at a significant level of 0.05. This coefficient meant that students' self-efficacy increased along with the level of learner control they had experience. The more in-depth study is planned for a larger and more diverse sample group in term of learner control after the questionnaire was adjusted and validated. Qualitative data, then, is analyses and used to triangulate the quantitative findings.

It is hoped that the results of this study may prove useful for educators and developers in shedding some light on how to make future online students more comfortable and confident in unfamiliar and complex online environments. Novice and inexperienced online students who possess low confidence in their ability might find it easier to interact, collaborate, and thus succeed in online courses when learner control is integrated into the online learning environment from the beginning as part of the course design.

An exploration in the inclusive teaching practices within a New Zealand university – Part one: Inclusive assessments

Ina Te Wiata
Massey University

Feona Sayles
Massey University

This demonstration is intended to relate some of the initial findings of research into the issues surrounding students with a disability when undertaking assessments.

Keywords: students, assessment, alternative, inclusive, disability, technologies

Introduction

The motivation to engage in this research partially arose due to the experiences of the one the researchers during early 2012 when a student with a disability requested if some of the learning materials could be made available in an alternative format that would be suited to his particular disability. The researcher had not previously thought in terms of how her learning environment catered for students with a disability. Discussion about both researchers practices, and reviews of relevant literature paved the way towards an understanding of the need to think 'inclusive' when designing a teaching programme. To enhance knowledge as to effective inclusive teaching practices, with the object of incorporating these practices in the researcher's university (Massey University or 'MU'), the researchers propose to explore current university policies, teaching practices/attitudes, and the experiences of learners with a disability. This research will begin by looking at assessments then later expand to incorporate other areas of teaching and learning and is a progression from prior research conducted by the researchers (Sayles, F.J. & Te Wiata, I., 2011), as a main focus will be on the use of technology to enhance inclusive learning.

Brief Summary of Literature

The ability to negotiate assessments and learning environments suited to students with a disability may not only be influenced by university policies but also the attitudes of those working within the university system (Bessant, 2012). This can include a reluctance on the part of the learner to request additional assistance, particularly if (s)he perceives it as enhancing difference between the learner and other learners (Seale, 2012). Developing assessment and learning environments that take account of students with a disability *at the start* of the planning stage can assist in overcoming some of these difficulties and may also enhance the learning experience of non-disabled students (Ball 2009). Part of improving this accessibility includes the use of technologies (Ball, 2009) in enhancing the student experience.

A quick overview of the literature on university students and their relationship with technologies shows a mixed picture of success regarding their learning experiences. This is illustrated by many researchers including, Bessant, 2012; Deepwell & Malik, 2008,Garland Thomson, 2012; Goode, 2007, and Kenney, 2012. Despite these mixed experiences, the role of technology in teaching has increased in the design of the learning environment.

Given that the technological abilities of students without disabilities play an increasing role in shaping how universities develop their approaches to teaching and learning support (Seale, 2012), the discourse surrounding students with disabilities also becomes important in understanding how university policies and practices are created. As Seale (2012) highlights, the discourse surrounding the technological abilities of the 'normate' (Garland-Thomson, 2007) student, is largely positive, (focused on what the students can do) whilst for students with disabilities the discourse is negative, focusing more on what they cannot do, and what is required to improve their accessibility to university teaching, learning and assessment practices. It has also been recognised (Ball, 2009) that one of the voices missing in this discourse and in the subsequent development of policies and practices is the voice of the student, as such any further research in this area should seek to provide a vehicle for these voices to be heard.

Methodology

In determining our methodological approach and theoretical framework for this project, we are drawing on the work of Bessant (2012), who, using an auto-ethnographic approach, studied a group of Australian university students with disabilities and their experiences in negotiations for alternative assessment practices. Using case studies and focusing on the perceptions of staff and students, both cultural and practical issues were identified, along with ideas on what needed to be done if a university was serious about addressing equity and inclusive education. The advantages of using the same approach as Bessant (2012) are twofold: the first is that we hope to increase our understanding of how well MU "measures up", and second, we can compare the experiences of various key parties of one NZ university with an Australian counterpart.

An auto-ethnographic approach follows the tradition of ethnographic research. (Denzin, N., & Lincoln, Y. (Eds.), but whereas the researcher is an "outsider", becoming an "insider" only as situation allows, an auto-ethnographic researcher recognises that she or he, is the "insider" (Duncan, 2012) . This then enables her or him, to embrace personal thoughts, feelings and observations as a way of understanding the social context which they are studying (Ellingson &Ellis, 2008). The selected sample of case studies we have chosen for this poster aims to provide insight into the worlds of students with a variety of disabilities using this approach. In following Bessant's framework, we intend to highlight some of the different wisdoms, irrationalities, feelings and biases which inform both judgment and action regarding students with disabilities by also using the personal pronoun model of Elias (1978).

This particular analytic perspective enables us to apply an, 'I', 'we' and 'they' model to our cases. We are however, cognizant that as the experience of students in our study increases and alters over time, the contexts will also inevitably change, thus we will need to be consider how much we are able to apply this model.

We also hope that like Bessant (2012), the use of the personal pronoun perspective with our case studies, will provide insights into what each of the key parties (students, staff and administrators) may be benefit from in working in an inclusive environment. Whether for example, support for staff is required in recognizing and appreciating their legal obligations, or professional development is needed, we hope that the results of this study will offer the university a way forward in improving the opportunities and learning experiences for all of its students.

Conclusion

This research project was initially started due to a personal interest on the part of one of the researchers to develop a more inclusive learning environment for her students. However, initial discussions with some key stakeholders have revealed that the research could have importance for the wider university as it progresses its vision for future, which includes an increasing expansion into attracting overseas students who are used to a different level of inclusive education.

Enabling students with disabilities to better connect with learning through the use of technologies may address some concerns, (it could be argued somewhat simplistically). However, our starting point for understanding what is happening or needs to happen at this university (MU), so as to create an equitable and inclusive environment for students, begins with a study which focuses on the assessment and students with disabilities. We intend to use the perceptions and experiences of students with disabilities, in negotiating alternative assessments (including the use of technologies), as a "vehicle" to inform both our own assessment practices, and the on-going development of university policy and practices. In doing so, we hope to initially help make assessments more student centred and inclusive, than what they are currently.

Online learning preferences: revealing assumptions and working with difference

Sue Tickner
University of Auckland

Tony Hunt
University of Auckland

This paper describes a trial of an online survey that was intended to reveal the online learning preferences of students and staff at a Faculty of Education, and our conclusions to date about the usefulness of the tool and the results it revealed. As part of a wider work in progress, the trial arose from our desire to better understand the learning needs of students from diverse cultures and how best to support online and blended students and teachers in increasingly global communities of learning. Our conclusions to date do not enable us to validate the cultural dimensions of learning on which the survey was based, but they do lead us to believe there is value in using the instrument to reveal and explore difference in online learning preferences.

Keywords: Online learning preferences; cultural dimensions

Introduction

Universities are facing a combination of challenges, many of which are likely to grow in the forseeable future. Among these challenges for New Zealand tertiary education, is an increasingly diverse student population, arising from rapidly rising immigration and expanding numbers of international students. Alongside these pressures there is a growing awareness of the needs of indigenous people and a recognition of difference in approaches to learning.

In New Zealand the proportion of Māori and Pasifika people participating in tertiary study is increasing while the numbers of students from other ethnic backgrounds is also growing. Ministry of Education statistics (Wensvoort, 2011) show that a decade ago the number of "European" students in tertiary education was around 70 percent, whereas in 2010 this had dropped to 59 percent, with 18 percent identifying as Māori, 8 percent Pasifika, 18 percent Asian, and 5 percent as from other groups. These figures include a significant number of International students, of whom 72 percent were Asian, together with students from Britain, Europe, Africa, Canada and the USA. Population projects show this trend continuing, particularly in Auckland.
Another major challenge is provided by the growth of online and blended learning which is breaking down barriers to connect communities of learners across social, ethnic and cultural backgrounds. Social software, open educational resources and mobile computing connect individuals with resources and networks which provide opportunities for informal as much as formal learning. An increasing number of online courses is offered at a distance to populations targeted as 'new' markets, with global competition for students. In the New Zealand context, these are mainly from Asian and Middle-Eastern countries.

The study that we report on here arose out of a desire to ensure that courses in the Faculty were designed to meet the needs of this diverse student population, through identifying culturally based factors which might affect student and lecturer engagement in online learning, and developing strategies to mitigate these effects.

Background

A survey of the literature relating to cultural differences and online learning, revealed a growing international concern based on these issues of educational globalisation. Several literature reviews examine culture and ethnicity in online learning environments, for example Rutherford & Kerr, (2008) and McAnany (2009). Some case studies illustrate differences in online learning behaviours that can be linked to cultural differences (e.g. Major, 2005) and provide recommendations for teaching practise. Others attempt to identify conceptual frameworks to account for such differences (Morse, 2003). Much of the literature on culture and learning stems from the model developed by Geert Hofstede (2008) and later colleagues. Hofstede's five-dimensional model was claimed to characterise behaviours (initially in corporate settings) that originate from different societies. The dimensions are: relationship to authority (small vs. large power distance); individualism vs. collectivism; masculinity vs. femininity; tolerance of uncertainty and ambiguity (uncertainty avoidance), and the fifth dimension: long-term versus short-term orientation, was later added as a result of studying Asian societies.

Many later researchers have applied or adapted this model to educational settings, for example to develop guidelines for culturally-inclusive teaching and learning and designing for diversity (McLoughlin, 2007).

The Cultural Dimensions of Learning Framework (CDLF) (Parrish & Linder-VanBerschot, 2010) describes eight key cultural dimensions regarding social relationships, epistemological beliefs, and temporal perceptions. The authors have developed a questionnaire (2009a) and analysis (2009b) based on the CDLF that can illuminate the range of preferences existing among learners.

Some literature focuses on national equity issues related to significant population groups. In New Zealand, for example, a body of research exists that focuses on Māori learning preferences and, to a lesser extent, on Pasifika students. However, as a recent report indicates, the bulk of published research relating to online learning emphasises the differences between 'Asian' and 'Western' learners (Guiney, 2012).

A strong message emerging from this survey of research is that both teachers and students need to be aware of their own cultural values and practices, as well as those of others, when they work together in an educational setting, online or face-to-face.

The current study

To us, the strategy of raising the mutual awareness of participants' learning approaches in online courses offered an appropriate way of meeting our goals within the Faculty. This has particular appeal within teacher education where a major concern is to raise students' awareness of their own role as teachers and develop their capacity for reflective practise (Major, 2005; Alton-Lee, 2003)

The CDLF questionnaire (Parrish & Linder-VanBerschot, 2009a) offered a potential tool for stimulating reflection and discussion in online courses, but there was no evidence of its validity, beyond face validity, or empirical data about its use elsewhere. We have, therefore, established an initial phase of the project to gather data on student and lecturer responses from online teacher education courses, with the intention of carrying out a factor analysis, and comparing responses between students and lecturers, and between students of different ethnicities.

Findings

Quantitative results

In the first semester of 2012 the CDLF questionnaire, with slight modifications to make the terminology relevant to online learning, was administered as an anonymous online survey to participants in 9 courses which make significant use of the Faculty of Education's Moodle online system, following ethics approval from the University of Auckland. Responses have been received from 57 of 122 students (47%) and 2 lecturers. The questionnaire will be administered to a further group in the second semester. The respondents were overwhelmingly female (97%) and covered a wide range of ages from 20 to over 50 years old, reflecting the programmes in which they were enrolled, which included pre-service (B.Ed. and graduate diplomas) and postgraduate, in-service qualifications. In light of our interest in cultural difference it is significant that most respondents (47 or 80%) identified themselves as European or Pakeha (a Maori word describing Europeans). Other respondents identified themselves mixed Maori and European (4), Samoan (3) including one part Chinese, Filipino (2), Indian, Latin American and Middle-Eastern.

The number of responses received so far do not provide enough data to carry out a valid factor analysis, but does give initial indication of some trends in student responses. In addition to completing the 36 items of the questionnaire, participants were given the opportunity to make open-ended comments about the survey and these provide some useful insights into student perceptions of online learning.

The questionnaire data has been initially analysed according to the eight dimensions with which Parrish and Linder-VanBerschott identified the items. Responses for most items show high variability and this is not necessarily a problem where the purpose of the instrument is to stimulate reflection and discussion. There are some identified dimensions within which the correlation between items is moderate to high, but there are also many correlations which are low and occasionally negative. A full analysis with more data will be required to establish how strongly the items are related to the dimensions identified.

It is interesting to note, however, the dimensions where there appears to be a high degree of agreement amongst the respondents to date. A score for each respondent was calculated for each of the proposed dimensions representing the mean ranking of the items associated with that dimension. Items had been ranked between the two poles of the dimension on a scale of 1 to 10. The means of these scores were computed for all respondents and a score between 1 and 3.5, or between 7.5 and 10 were taken as implying strong preferences for the polar positions.

These mean scores indicated that there was a strong preference, on average, for an equality-oriented approach to learning rather than an authority-oriented approach (m=3.06, s.d.=1.19), nurturing compared with challenging (m=2.74, s.d.=1.06), and for uncertainty-accepting compared with stability-seeking(m=7.32, s.d.=1.24). Despite the apparent high degree of agreement between respondents, there were some individuals whose choices were very different; this supports the belief that the questionnaire might enable individual students to develop awareness of how their approaches to learning differ from the approaches of others, and to alert lecturers to these individual differences.

Qualitative results

Included in the amendments we made to the CDLF questionnaire was the addition of a final open question inviting comments on the survey. We felt that our audience, in a Faculty of Education, would be sufficiently aware of educational research to be likely to give valuable feedback on the instrument. In fact, whilst a small minority made some superficial comments on the questionnaire, more interesting were the comments reflecting on online learning.

Less than half of respondents made open comments. However within these there seemed a possible bias towards the ‘authoritarian’ end of the scale, with an apparent student preconception that the responsibility for creating the learning experience rests with the lecturer. One learner expressed a wish for lecturers to close discussions after they (the lecturer) had posted ‘closing’ comments, as this student didn’t want to have to ‘waste time’ going back to view the comments of her peers after that. Another stated that the best lecturers had given her ‘the necessary push’ when needed, and wanted recordings, to listen to lecturers ‘lecturing’ more often. Teacher-led discussions seemed to be in demand by a few respondents, which felt at odds with the espoused socio-cultural approaches of most lecturing staff in the Faculty. Whether these comments reveal a mismatch between online teaching styles and online learning preferences would require more data from lecturers, as well as discussion with the students concerned. Furthermore there seemed little correlation between the individuals’ comments and where they placed themselves on the scales for relevant dimensions. The two respondents who made the comments above, for example, placed themselves clearly in the quality-oriented approach to learning over an authority-oriented approach. One response appeared to arise from an individualistic preference:

> The online forum is very powerful. It gives me ownership over who I choose to 'listen to' and engage with. I used to find it a frustrating waste if my time when lecturers had to repeat themselves for students who did not understand concepts. The online forum is much more efficient for learning in my opinion.

Yet this student placed herself at the collectivist end of the scale. Another respondent mentioned that as a student-practitioner, their answers were given partly as a student and partly as a teacher. We would like to interview students, and to examine whether there is cognitive dissonance in these roles in online learning preferences.

Conclusion

Soon after embarking on our project we became aware of related research. The HEART (Hearing And Realising Teaching voice) tools support teachers and learning designers involved in planning, developing or reviewing course (or learning) designs (Donald et al, 2009). The tools are intended to help make explicit teaching beliefs and educational practice in learning designs. At an early stage the HEART researchers also explored the CDLF questionnaire for their purposes, but have since based their work on Bain and McNaught’s 13 belief/practice dimensions (Bain & McNaught, 2006).

We, however, are primarily interested in revealing learner preferences, and as a result of the additional open ended comments in our survey, we feel more confident that the value of the CDLF is in the wider discussions that it could stimulate, about the nature of good online learning experiences and individual preconceptions of learning**.** Strategies which encourage students to examine their epistemic beliefs and approaches to learning appear to be important, particularly when they are, themselves, teachers.

By the time of the conference we will have more data, and aim to interview students about their responses, after asking them to place themselves on the scale for each question. The next stage of the project will be to explore how this approach can be incorporated into regular teaching of online courses, and whether this is beneficial for student learning.

We understand from the authors of the CDLF questionnaire that data is being gathered from other trials of the instrument with a view to refining the dimensions. Although our questionnaire was modified for online courses, we have agreed to contribute our data to a growing global collection to enable future analysis of a critical mass of findings.

Mobile learning, exploring the possibilities for rangatahi

Travis Timoko
Te Wananga o Aotearoa

This paper presents the findings of a small exploratory study that evaluated the effectiveness of mobile learning to supplement the face-to-face teaching and learning of a whakairo (Māori carving) three-day course for secondary school age Māori. The study found that in relation to participant learning, the use of mlearning to supplement the learning experience appeared to improve the knowledge transfer or ability to recall key elements relevant to the course for the experimental group. This study forms the basis for further research in the area of mlearning for secondary school age students within tikanga Māori learning environments. It is anticipated that the research will contribute to a tikanga-based framework, shaping the future of learning in Aotearoa.

Keywords: Māori, mobile learning, teaching and learning, secondary schools.

Mobile learning

The uptake of mobile devices, such as mobile phones and MP3 players has, over recent years, overtaken the proliferation of personal computers in both modern professional and social contexts (Herrington, 2009). With the ubiquitous uptake of mobile devices coupled with their ever-broadening technological advances and applications, mobile technologies have set alight the imagination for use within education.

> Mobiles embody the convergence of several technologies that lend themselves to educational use, including electronic book readers, annotation tools, applications for creation and composition, and social networking tools. GPS and compasses allow sophisticated location and positioning… …digital capture and editing bring rich tools for video, audio and imaging – more and more, mobiles encompass it all, and innovation in mobile device development continues at an unprecedented rate. (Johnson, 2011).

Johnson succinctly captures and highlights the current state of mobile technology in its broadest applications. While advances in technology continue to broaden the use of mobile devices for educational purposes, the field of mobile learning is still evolving (Traxler, 2007). It was within this broader context of mobile learning (mlearning) that a small exploratory study was conducted to evaluate the effectiveness of mlearning to supplement the face-to-face teaching and learning of a whakairo short course.

The rationale for evaluating the effectiveness of mlearning

The rationale to explore the use of mobile technologies for teaching and learning within the organization that the study occurred, was to contribute to an informed position on the use and application of mobile technologies for educational purposes.

A whakairo (Māori carving) short course (three days) was identified for the study as the course was already being delivered, it had been developed so successful completion would attain unit standards, and the visual dimensions inherent within the practice of whakairo readily lends itself to the media rich presentation capabilities of mobile devices (accordingly, the iPod touch was selected, in part, for its media capabilities). The purpose of the course was for students to be able to describe aspects of their lineage, heritage and cultural identity. A whakairo instructor delivered the course and the learning was then conveyed and captured through workbook completion and the medium of student designed whakairo pattern.

The exploratory study

The course was delivered one day a week over three weeks. The first aspects covered by the course include whakapapa (genealogy) and its importance to Te Ao Māori (Maori world view), whakawhanuangatanga (process of establishing relationships) and mihimihi (speech of greeting). The course then covers the key whakairo concept of whakarei (surface patterns) and provides visual examples in the learning journal of the many different styles used, their basic meaning and tribal origin. The course provides the opportunity for students to practice drawing each type of whakarei (surface patterns) before they are required to design their own pattern that captures and symbolically depicts their individual cultural identity. At about the halfway point of the course, the steps involved in carving-out whakarei are presented so students can carve-out their design. This course was delivered to two cohorts at two separate locations. There were 11 participants in Cohort A (control group) and 19 in Cohort B (experimental group). All participants self identified as being Māori. In addition to the face-to-face classroom instruction of the course, Cohort B received a mobile device to supplement the learning experience. The experimental materials for each condition are described below.

For the Cohort A classroom instruction condition the Whakairo Short Introductory Course was delivered (face-to-face) within the school marae on the first day, a school classroom on the second day and a technical facility for the final carving day. The technical facility was equipped with workbenches and vices for the purpose of whakairo. Haehae (chisels) and pao (mallets) were provided and the whakairo learning journal was provided to students for completion.

For the Cohort B classroom instruction condition, the STAR Whakairo Short Introductory Course was delivered (face-to-face) within a whakairo room. The technical facility was equipped with workbenches and vices for the purpose of whakairo. Chisels and mallets were provided and Whakairo learning journal were given to students to complete. In addition, students in Cohort B were loaned an iPod for the final week of the course. On the iPod was loaded several videos, including the CEO welcoming students through mihimihi (welcome, included lineage) and overviews of the concepts of kaupapa and whakapapa, presented by members of the Cultural Office. Video recorded sessions of the different whakarei (surface patterns) being carved into particleboard, including the name of each pattern and the carving stages were also displayed on the iPod video (refer Figure 1).

Figure 1: iPod video of whakairo pattern being carved into particleboard (example only)

For each cohort, pre-course questionnaires were administered to form a baseline of student's existing experience and understanding of whakapapa, mihimihi, whakarei, kowhaiwhai, pao and haehae. A post-course questionnaire was also administered to cohorts to gain their reactions through self-ratings. The questionnaire also provided space in which students could comment on aspects they liked least, and liked most about the course. As per the pre-course questionnaire, the post-course questionnaire again prompted students understanding of the courses key concepts (whakapapa, mihimihi, whakarei, kowhaiwhai, pao and haehae).

The study findings

The study found that overall satisfaction of the course was high, with slightly higher levels of satisfaction reported by Cohort A (control group), than Cohort B (experimental group). Of interest to the study objective, Cohort B indicated that they enjoyed getting an iPod touch to use but equally did not enjoy giving the iPod back. In relation to understanding the course key concepts, each cohort improved after completing the course. However, results indicated that Cohort B displayed an improvement in knowledge or ability to recall the meaning of the above elements than the Cohort A participants. In summary, the use of mlearning to supplement the learning experience may improve the knowledge transfer or ability to recall key elements relevant to the course.

Moving the exploratory study forward

After completing the study, questions arose about how mlearning might best be applied for Māori students. These questions were influenced by the observation that the study simply loading edited video information to a mobile device for students to view presented limitations. Alternative approaches for using mobile devices could yield substantially greater gains for participants through podcast productions and authentic e-learning.

Podcasting

Progressing from mere information consumption is the use of mobile devices for capturing and compiling information that can be delivered or presented to others through, for example, podcasts. The term podcast refers to the development and subsequent distribution of digital audio / video files manually from the Internet or automatically through subscriptions (Buffington, 2010; M. Lee & Chan, 2007; McGarr, 2009; Shumack & Gilcrest, 2009). At the risk of not fully exploiting the possibilities offered by mobile technology as highlighted by Herrington (2009), podcasting as a means of content delivery also offers relatively low barriers of access to produce knowledge and learning resources (M. Lee & Chan, 2007). These resources can augment the learning experiences of students by preparing them for an upcoming learning topic or session, or potentially be submitted for (formal) assessment. This is highlighted by the audio or video recording functions of mobile devices, the ease of access and increasingly intuitive nature of editing software, and the availability of subject matter expertise, providing the foundation for near instant development and distribution. Listening or viewing these files can be done directly from the PC desktop or via a mobile device such as an MP3 player (Buffington, 2010; M. Lee & Chan, 2007; McGarr, 2009; Shumack & Gilcrest, 2009).

Three broad categories presented by McGarr (2009) relating to the purpose of using podcasting, these are: substitutional, supplementary and creative use. At the basic level, podcasting substitutes the traditional lecture and are best suited to revision and review of passive information. The use of podcasts to provide supplementary material is of significantly more educational value, especially if the material is in addition to that provided from the lecture. Creative use refers to the construction of knowledge by students through a deep understanding of the subject matter to construct a podcast. McGarr explains that this type of use of podcasting occurs least in the literature. Similarly, Lee, McLoughlin & Chan (2008) hold strongly to the belief that knowledge creation and its ability to disseminate learner-generated content is the true potential of podcast technology.

Authentic e-learning

The concept of authentic e-learning, as described by Herrington, Reeves & Oliver (2010) occurs when learners are engaged in “an inventive and realistic task that provides for complex collaborative activities” (p.1.). Herrington et al., (2010) identify nine key elements of authentic e-learning which form a framework for the design and production of authentic e-learning courses, these elements relate to; an authentic context, authentic tasks, access to expert performances and modeling of processes, multiple roles and perspectives, collaborative construction of knowledge, reflection, articulation, coaching and scaffolding, and authentic assessment.

Herrington et al., (2010) explain that the purpose of authentic learning is to ensure that the knowledge obtained from the learning experience will be more likely to be used for problem solving situations. This claim is contrasted against the concept of inert knowledge, whereby principles, facts and concepts are taught in abstract and decontextualised form. The problem with the latter approach means that the knowledge cannot be readily retrieved and applied to a given situation, as information has been stored as facts and not as tools. As an example, viewing information simply provides a ‘window’, whereas authentic learning provides students with a ‘door’ through which they can engage with the information on a practical level.

Relevance to Aotearoa New Zealand

The convergence of several complimentary factors within the Aotearoa context also necessitated further review of mlearning, including the increasing uptake of smartphones, schools (soon to be) connecting to ultra fast broadband, a growing emphasis on NCEA attainment for target groups, and the need for increased ICT skills for students to be successful 21st century citizens.

Seemingly, most young people have at least a mobile phone in their possession and, if their mobile phone does not offer the capability, they may have a digital music player as well. Price, both in terms of the devices and the related network charges (for mobile phones), were significant barriers to access. However, advances in technology have made these devices widely and progressively more available (Hung & Zhang, 2012). As such, the use of mobile phones and increasingly smartphones are an ubiquitous feature of today’s society.

In a recent press release (National Government, 2012), the Minister of Social Development, the Honorable Paula Bennett, signaled that the Ministry has placed a priority on supporting young people (16 to 17) who have been disengaged from education and re-engaging them under its Youth Services initiative. This initiative stems from the looming issues currently prevalent among young people, a problem faced disproportionately by Māori (and Pasifika) (Ministry of Education, 2011a). Although overall improvements in performance have lifted in the education system over the last ten years, the Ministry of Education acknowledges that although the education system works for some learners it is not suitable for others (Ministry of Education, 2011a).

The Ministry of Education, in its statement of intent 2011/ - 2015/16 (Ministry of Education, 2011b), places greater emphasis on using technology in learning and improving outcomes for Māori students. Accordingly, the Ministry expects the following; use of modern technologies that supports and increases student achievement as well as effective and efficient teaching and learning; more Māori gaining NCEA level 2 qualifications and above; culturally responsive teaching that is high quality and effective; relevant skill and qualification attainment; and approaches that ensure Māori are achieving education success as Māori. Each of the above contributes to the Ministry's vision to be a "world-leading education system that equips all New Zealanders with the knowledge, skills and values to be successful citizens in the 21st-century" (Ministry of Education, 2011b).

A research proposal

It is from the potential of integrating these broad and loosely defined areas that research is being proposed to further explore mlearning for Māori. More precisely, it will seek to find an effective way to use mobile technology to engage young people in formal learning to produce positive learning experiences. Positive experiences could include something as simple as having fun or learning something new from the internet, through to something more complex like the construction of a video presentation as a piece of assessment towards specified learning criteria. As mlearning is relatively new, there does not appear to be any research relating to tikanga Māori based mlearning activities and accordingly there is no literature available on effective practices or experiences associated with such activity. While these practices undoubtedly are occurring, they do not appear to be published within the research literature. It is anticipated that the proposed research will contribute to a tikanga-based mobile learning framework to shape the future of learning in Aotearoa.

Ensuring an excellent learning experience is critical for the modern Australasian university. This is particularly important for an institution like CSU, which has the majority of its students studying at a distance. This paper presents a snapshot of student usage and attitudes towards technologies for learning and teaching, drawing on an institution wide online questionnaire in 2010 completed by 3952 students. One of the most interesting findings from this study is that students' use of educational technologies may be driven primarily by the need for their studies to be flexible and manageable around work and family demands. Students appear to be 'digital followers' rather than early adopters but are nevertheless very regular users of technologies in their own lives, and appear very receptive to the frequent use of technologies in their studies.

Keywords: Technology adoption, eLearning, Educational Technology use, students, Charles Sturt University

Introduction

Charles Sturt University has a very large and diverse cohort of students studying both undergraduate and postgraduate degrees, with many studying by distance or online. CSU has been one of the largest providers of distance education in Australia and consequently has maintained a keen interest in the use of educational technology to enhance delivery of this mode. As a university that engaged early with the development of learning management systems and other technologies that support the online delivery of higher education courses, CSU are in a good position to reflect upon the use and developments of our educational technology over time. With this in mind, it is important to ensure we build and promote sustainable systems of educational technologies that address the needs and uses of all stakeholders. Consequently, this study was initiated to explore the nature of students' use, preferences and familiarity with the use of educational technology while studying at CSU, either via distance or as an internal student.

Background

In the early part of this decade, much of the academic debate about attitudes towards and use of technology by university students was framed by Prensky's (2001) conjecture that today's students are 'Digital Natives', while their teachers are 'Digital Immigrants', and similar conceptualisations of students as being part of a 'Net Generation' who had grown up surrounded by technology use and therefore had much greater expectations of a technology enriched learning experience than previous generations (Oblinger and Oblinger, 2005). This led to a number of large empirical studies which tended to find, firstly, that age differences were not the primary factor distinguishing between student attitudes towards and use of technologies in their private lives and studies, and secondly that many students fitting the age criteria for being a 'Digital Native' or part of the 'Net Generation' were not in fact frequent or highly competent users of a wide range of technologies, and were not calling for a technology driven transformation of their university learning experiences. For example, in the largest Australian study in this area, Kennedy, Krause, Gray, Judd, Bennett, Maton, Dalgarno, and Bishop (2006) surveyed 2588 students at three universities in 2006, and found substantial diversity in technology usage and found that this diversity was largely not attributable to student age (see Kennedy, Judd, Dalgarno, & Waycott, 2010). Studies overseas undertaken during the same time period found similar results and in general tended to present a more complex picture than that proposed by commentators such as Prensky (see, for example, Salaway et al., 2007 in the US, and Jones, Ramanau, Cross & Healing, 2010 in the UK).

Alongside this empirical work, a number of scholars have also criticised Prensky's methods (see, for example, Sheely, 2008) while others, such as Bennett, Maton and Kervin (2008) have commented on the fervour with which his ideas were taken up, suggested that educators need to take a more measured stance and called for "considered and rigorous investigation that includes the perspectives of young people and their teachers, and genuinely seeks to understand the situation before proclaiming the need for widespread change" (p. 784). Senn (2008) also noted that early ICT implementation neglected consideration of student preferences and that staff willingness and/or institutional capacity to provide the level of online interaction promoted by some educators and theorists were often limited.

Communication and interaction between students and students, and students and their lecturers remain key elements of learning in higher education and many educational technologies have had a significant impact on the ways in which this communication is facilitated. The universal use of the internet in higher education has brought with it new social norms in terms of social interactions (Dykman & Davis, 2007), however, less universal has been the development of educators' communication skills to incorporate these changes into their teaching (Moller, Foshay & Huett, 2008). For an institution to begin to appropriately address these issues they must first understand how their students and staff are using ICT and what tools they prefer.

Recent studies have begun to present a picture of noticeably greater usage of technology by university students. For example the latest in a series of annual studies of undergraduate students' use of technology undertaken by the EDUCAUSE Centre for Applied Research in the US, which involved a sample of 3,000 students in 1,179 colleges and universities, found: very high levels of ownership of technologies such as laptops (87%), iPods (62%) and smartphones (55%); very high proportions of students using Facebook (90%), reading Wikis (85%) and blogs (72%) and sizable minorities also using other tools such as Twitter (37%) and contributing to blogs (43%); and very high proportions of students agreeing with a series of statements about the benefits of technology for learning (Dahlstrom, de Boor, Grunwald & Vockley, 2011).

The Study

CSU Context

Charles Sturt University is a multi-campus university with a large proportion of its students studying at a distance rather than on campus. Specifically, in 2010 23,367 students were enrolled in Distance mode, 9,568 in On Campus mode and 5,029 in a mixture of On Campus and Distance modes. In 2010 the University employed 673 full-time equivalent academic staff, in four faculties (Arts, Science, Business and Education), as well as adjunct staff in a number of partner institutions within Australia and offshore. The University has required all subjects to have an online presence containing at least the subject outline and a discussion forum since the late 1990s, with online assignment submission available in all distance subjects since the early 2000s. The Sakai based Learning Management System (named Interact within the University) was introduced in 2008, providing an announcements tool and a resource sharing tool in all subjects and tools such a blog, a wiki and a chat room at the discretion of the subject coordinator.

Questionnaire Design

The questionnaire was designed in close cooperation with staff from the University of Waikato, New Zealand in mid-2010. The questionnaire was based on the following surveys: University of Waikato, Staff and Student eLearning surveys 2008; ECAR Research study 6, 2007; Student Information and communications Technology project, University of Edinburgh; Association of College and Research Libraries, Informing Innovation survey 2009; VERSO, 2008; UNSW@ADFA, Students' ICT Experience, 2008; Victoria University, Student Questionnaire, 2009; Macquarie University, Student Experience of Technologies in Universities, 2010; University of Wollongong Survey, 2008; UTAS, Staff and Student experience with eLearning technology surveys 2010.

The questionnaire was thereafter customised to address key concerns about educational technology at CSU and had the following sections: Demographics – Personal; Demographics – Institutional; Technology Access; Use and awareness; Features currently used; Features they would like to use to support their learning; Views and Experience; University Services. As well as the questionnaire completed by students, which is discussed in this paper, a similar questionnaire was designed and administered to CSU staff.

Administration and Sample Demographics

The questionnaire was made available online in Survey Monkey between 13 July 2010 and 1 August 2010. It was widely promoted in CSU and its partner institutions through general communication channels and also through CSU's micro-blogging tool Yammer and a learning management system site called "About ICT integration" (which had just under 500 members). Ethics approval for this survey was obtained from the CSU Learning & Teaching Services Ethics Committee.

The survey was conducted anonymously and it was made clear that even though Survey Monkey used the IP address of the computer to enable students to continue if they exited the survey before the end, this would not be used to identify their contribution. It was also made clear that any publication as an outcome of this survey would not identify any individual or any particular subject in any way.

Students were encouraged to complete the full questionnaire, but could exit the survey at any time and return later to finalise it on the same computer or exit without completing. It was stated that participants had the right to withdraw from the research at any time, without penalty and they could also contact the author of the paper if they wished to withdraw after having completed part of the survey. The survey took approximately between 30 and 45 minutes to complete. This paper reports summaries of the responses to a subset of the questions in the survey relating to general attitudes towards and usage of technology, attitudes and usage of selected educational technologies, and usage of the CSU Learning Management System. Generally items have been chosen for reporting where it was considered that their usage was sufficiently common across the sector to warrant wider interest.

The survey was completed by 3952 students, including 1314 males, 2625 females, and 13 not stating their gender. There were 753 respondents from the Faculty of Arts, 882 from Business, 1000 from Education and 1221 from Science, with 96 not responding to the question. 1278 respondents indicated that they were aged 40 or over, 1419 were 26-39, 1250 were 18-25 and 5 indicated that they were less than 18. Of the respondents, 403 were international students and 3453 were domestic students. In terms of study mode, 2673 were distance students, 814 on-campus and 369 were mixed mode. 998 respondents identified as Undergraduate (Year 1), 541 as Undergraduate (Year 2), 838 as Undergraduate (Year 3 or more), 1081 as Post-graduate (Course work), 202 as Post-graduate research or higher degrees and 196 as other.

Findings

Attitude towards technology

Students were asked to choose which of a series of descriptors relating to their attitudes towards new technologies best described themselves. The descriptors ranged from "I love new technologies and am among the first to experiment and use them" to "I am sceptical of new technologies and use them only when I have to". The results (see Figure 1) show a reasonably even distribution of responses. At one end of the scale, 8.7% of students indicated that they loved technologies and were among the first to use them, and 23.5% of students indicated that they liked technologies and used them before most people they knew. At the other end of the scale 3.8% of students indicated that they were sceptical of new technologies and 8.9% indicated that they were one of the last to use new technologies. The largest group of respondents (31.6%) were in the middle, indicating that they use technologies when other people start to use them.

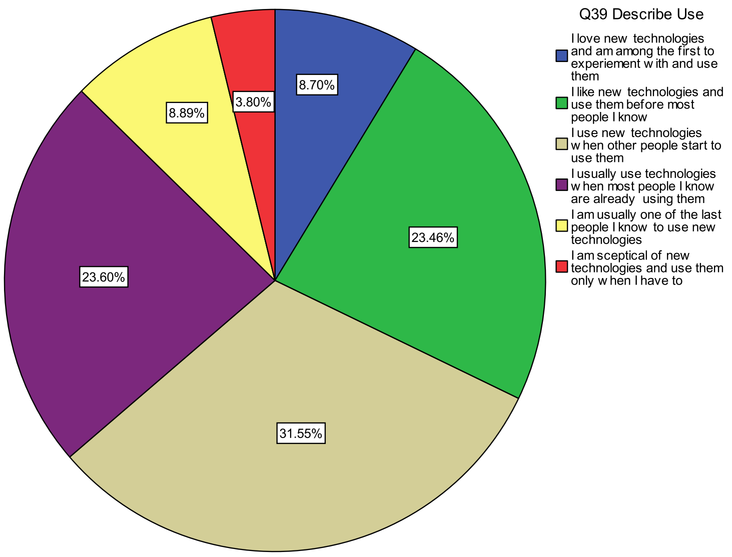

Figure 1: Attitudes towards new technologies

Usage of technology in general

Students were provided with a list of 60 technologies, tools and online information sources and asked to indicate in each case whether they had never heard of the technology, heard the name but were not sure what it was, knew what it was but had not used it, used it occasionally, or used it regularly. Table 1 shows responses relating to a selection of 16 of these 60 technologies. Tools used regularly by the majority of students included email (94%), spreadsheets (58%) and CSU Interact, the university's Sakai based Learning Management System (79%). Tools used either regularly or occasionally by the majority of students included presentation software (49% regularly and 36% occasionally), social networking (46% regularly and 27% occasionally), electronic library resources (46% regularly and 31% occasionally), and discussion forums (36% regularly and 36% occasionally). At the other end of the spectrum, the majority of students had either not heard of or were unsure what the following technologies actually were: ePortfolios (41% not heard of, 26% unsure of), web conferencing (34% not heard of, 23% unsure of), and electronic simulations and virtual worlds (34% not heard of, 20% unsure of). Technologies for which there was divergent levels of awareness and use, included Google Scholar (18% never heard of, 21% using regularly) and wikis (12% never heard of, 16% using regularly).

Table 1: Technology Use and Awareness

	Never heard of it (1)	I've heard the name but not really sure what it is (2)	I know what it is but have never used it regularly (3)	I use this occasionally (4)	I use this regularly (5)	*Mean*
Social Networking	.5%	2.7%	23.1%	27.3%	46.4%	4.16
Google Scholar	18.1%	13.3%	19.4%	28.0%	21.2%	3.21
Electronic Library Resources (e-journals/electronic databases)	2.1%	4.9%	16.9%	30.5%	45.6%	4.12
ePortfolios	41.2%	25.6%	21.9%	8.3%	3.0%	2.06
Webconferencing (e.g. Elluminate, Wimba, Dim Dim)	33.7%	23.4%	31.6%	8.2%	3.2%	2.24
CSU Interact	1.6%	2.4%	4.8%	11.8%	79.4%	4.65
Email	.2%	.1%	1.6%	3.7%	94.4%	4.92
Discussions Forums	.9%	3.0%	23.4%	36.6%	36.1%	4.04
Wikis	12.2%	11.7%	30.5%	29.9%	15.6%	3.25
Electronic Simulations and Virtual Worlds (e.g. Second Life)	33.8%	20.3%	40.2%	4.0%	1.8%	2.20
Social Bookmarking (e.g. Delicious, StumbleUpon)	50.6%	16.7%	24.7%	5.5%	2.6%	1.93
Microblogging Services (e.g. Twitter, Tumblr, Yammer)	10.2%	20.0%	57.3%	8.3%	4.1%	2.76
eBooks	4.2%	10.3%	44.5%	27.4%	13.6%	3.36
Podcasts	4.8%	13.5%	42.5%	28.3%	10.8%	3.27
Spreadsheets (e.g. MS-Excel)	.4%	1.5%	10.6%	29.2%	58.4%	4.44
Presentation software (e.g. PowerPoint, Keynote)	.5%	1.8%	12.7%	36.2%	48.8%	4.31

Attitude towards educational technologies

In order to gauge students attitudes towards the use of technology for learning, students were asked to nominate the “single most important benefit for me of using educational technology in my subjects”, choosing from six options. As shown in Table 2, the most frequently chosen benefit was “access (would have been unable to attend some or all of the required on-campus classes e.g. due to distance, family commitment)” (38%), while 27% chose the somewhat related reason “personal management (able to study at times and in places convenient for me”. Only 24% chose “improving my learning”, while only 8% chose “communication with teachers and classmates”. These results would suggest that access to information in a convenient way is still the most important application of technology. The low proportion of students (1%) indicating that they could see no benefits in the use of technology is encouraging.

Table 2: Most important benefit of using educational technology

The single most important benefit for me of using educational technology in my subject	
Improving my learning (1)	24.4%
Access (2)	37.7%
Personal management (3)	27.2%
Communication with teachers and classmates (4)	7.8%
No benefits (5)	1.3%
Other (6)	1.6%
Mean	2.29

Use of the Learning Management System

Students were asked to respond to three statements about their overall experience of the university Learning Management System (LMS), which goes by the tag "CSU Interact", rating the statements on a scale from "very strongly agree" to "very strongly disagree" and including an option for "not applicable". The first statement was "My overall experience of the functionality of CSU Interact has been positive" with 81% of students agreeing and 10% of students disagreeing. The second statement was "My overall experience of the availability of CSU Interact has been positive" with 80% of students agreeing and 11% of students disagreeing. The final statement was "My overall experience of the use of CSU Interact has been positive" with 81% of students agreeing and 9% of students disagreeing. Table 3 shows all responses to the three statements.

Table 3: Overall experience of using CSU Interact

	Very strongly agree (1)	Strongly agree (2)	Agree (3)	Uncertain (4)	Disagree (5)	Strongly disagree (6)	Very strongly disagree (7)	Not applicable (8)	*Mean*
My overall experience of the functionality of CSU Interact has been positive	14.1%	26.7%	40.1%	7.7%	6.4%	1.6%	2.1%	1.2%	2.85
My overall experience of the availability of CSU Interact has been positive	14.6%	26.9%	38.7%	8.0%	6.9%	1.9%	1.8%	1.3%	2.85
My overall experience of the use of CSU Interact has been positive	14.2%	27.1%	39.7%	8.5%	5.8%	1.6%	1.8%	1.3%	2.83

Current and desired usage of selected technologies in learning

Students were asked to indicate the frequency with which their lecturers use each of 34 technologies in their subjects and the frequency with which they "would like" their lecturers to use each of these technologies, on a scale where 1 = "more than once per week" and 5 = "never". These results were then collapsed to a 3 point scale, from "weekly or more" to "never". Table 4 shows the percentage of responses in each category for 10 of these technologies. By far the most frequently used technologies were the discussion forum and the online announcements tool in the LMS. Such tools have been in use at CSU for a number of years and have been very widely used in both on campus and distance mode teaching. Other tools being used at least sometimes in some subjects taken by the majority of respondents but generally less than weekly, included the chat room, online assignment marking, and online quizzes. It is interesting to note that a sizable minority of students have experienced the use of wikis, blogs and lecture recordings in their studies.

By comparison, students' desired frequency of use of technology in their studies is noticeably higher than the actual frequency. Technologies with particularly high desired use but only moderate actual use include lecture recording (58% desiring weekly use, while only 18% reporting actual weekly use), the chat room (52% desiring weekly use, while only 27% reporting actual weekly use) and online quizzes (40% requesting weekly use, while only 14% reporting actual weekly use). Other technologies for which a large proportion of students desire at least occasional use include the provision of subject information on handheld devices (50% desiring use, while 15% reporting actual use), online assignment marking (94% desiring use, while 61% reporting actual use), and Blogs (64% desiring use, while 32% reporting actual use).

Table 4: Frequency of use and desired use for selected educational technologies by lecturers

	Frequency of Current Use			Frequency of Desired Use		
	Weekly or more (1)	Less than weekly (2)	Never (3)	Weekly or more (1)	Less than weekly (2)	Never (3)
Announcements	54.5%	40.9%	4.7%	74.3%	24.3%	1.4%
Lecture recordings	18.1%	25.5%	56.5%	58.4%	27.7%	13.9%
Discussion forums	63.6%	26.8%	9.6%	72.2%	21.7%	6.0%
Chat room	27.0%	30.2%	42.8%	52.3%	28.1%	19.6%
Wikis	12.7%	29.7%	57.5%	33.2%	36.0%	30.8%
Blogs	11.1%	21.3%	67.6%	31.7%	32.3%	36.0%
ePortfolios (PebblePad)	6.6%	17.5%	75.9%	22.0%	33.4%	44.60%
Assignments - getting marked work back online	7.8%	53.1%	39.0%	30.1%	63.4%	6.50%
Quizzes for learning/self review/assessment	13.8%	41.4%	44.8%	40.4%	48.8%	10.80%
Subject information on my mobile device (handheld)	6.7%	8.8%	84.4%	28.5%	21.0%	50.50%

Comparison by Study Mode

A Multivariate Analysis of Variance (MANOVA) was also used to compare the mean frequency of use of a range of technological tools within subjects undertaken by respondents enrolled on campus and in distance mode (see Table 5). Students were asked to indicate the frequency with which their lecturers used specific technologies in their teaching on a scale where 1 = "more than once per week" and 5 = "never". The results show small but statistically significant differences for most of the selected technological tools. Particularly noticeable differences include announcements, ePortfolios and tracking progress and grades e.g. Gradebook (all of which were used more in on-campus or mixed mode subjects than distance subjects).

Table 5: Frequency of use of specific technologies lecturers currently use

	Study mode Mean response on frequency of use of specific technologies lecturers currently use					
	Distance (n = 2673)	On-campus (n = 814)	Mixed (n = 369)	All students (n = 3952)	F	p
	Mean	Mean	Mean	Mean		
Announcements	2.56	2.08	2.08	2.42	83.518	<.001
Online readings	2.93	2.73	2.59	2.86	15.678	<.001

Notifications sent to my mobile device (handheld)	4.71	4.52	4.71	4.67	11.652	<.001

Discussion and conclusion

The respondents to the question about students' attitudes towards technology suggest that only a small proportion of respondents (8.7%) "love technologies and are among the first to experiment with and use them " and a minority (23%) "like new technologies and use them before most people" (see Figure 1). The average CSU student who responded to the survey in 2010 was clearly a digital follower, rather than an early adopter of new technologies. However, it is interesting to compare the frequency of usage of technologies such as Social Networking by the students responding to this 2010 questionnaire with the frequency reported by the students responding to the 2006 questionnaire reported in Kennedy et al. (2007). As shown in Table 1, 73% of students responding to this questionnaire used Social Networking regularly or occasionally, compared to only 44% of students responding to the 2006 questionnaire. On the other hand, the percentage of these students using presentation software such as PowerPoint regularly or occasionally (84%) was very similar to 89% reported by Kennedy et al. (2006). This suggests that even though the self reported orientation to technology does not imply that these students are necessarily 'Digital Natives', their regular use of both productivity technologies and social technologies does suggest that they are now well prepared for the use of technologies for learning.

Students' responses to the question about the most important benefit of using educational technology suggested that students' current use of educational technologies appeared to be driven by a desire for flexibility in their non-virtual world, with 38% specifying "Access" and 27% choosing "Personal management" as the most important benefit and only 24% choosing "Improving my learning" (see Table 2). Broadly speaking, the technologies most frequently used by students tended to be those that facilitated asynchronous communication, including email (see Table 1), and online forums and announcements (see Table 4) as well as technologies used for assignment production such as spreadsheets and presentation software (see Table 1). The desired shift in educational technology use as expressed by students (see Table 4) tended to focus on those that support 'time-shifting' or increased flexibility, such as increased use of online announcements, recorded lectures and asynchronous discussion forums. Also noteworthy was a desire for an increase in the use of synchronous interaction through chat rooms.

Student responses to the questions asking them about their desired frequency of use of a range of technologies suggest that in general they have a very strong preference for the use of technology in their learning, with the majority of students wanting to see technologies such as online announcements, recorded lectures and discussion forums used at least weekly. Looking at this in conjunction with their responses to the questions about the experience with CSU's online learning platform, Interact (for example 82% agreeing that their overall experience of the functionality of CSU Interact has been positive), provides an overall impression of a student body very enthusiastic about the ways in which technologies are being used and very keen for increased usage. This is consistent with the results of the most recent EDUCAUSE study in the US (see Dahlstrom, de Boor, Grunwald & Vockley, 2011).

The comparison of the use of technologies by distance and on campus students provides some interesting findings, which may reflect the differing learning needs of these cohorts as well as the opportunities provided by their lecturers (see Table 5). For example, the greater use of forums and chat rooms in distance mode subjects probably reflects the fact that for these students such technologies provide the main avenues of communication with their peers and lecturers. Similarly, the higher use of electronic assignment submission in distance subjects reflects the fact that for these students the only other alternative is to mail their assignments, and because they have to arrive at the university before the due date, this results in lost time to work on the assignment. By comparison, on campus students can hand deliver their assignments and so electronic submission is not as important. The greater use of electronic announcements in on campus subjects may reflect the fact that these announcements often relate to late breaking information about the subject delivery. The higher use of quizzes for on campus students is somewhat surprising, although the usage appears to generally quite low. The higher use of electronic return of assignments in on campus subjects is also surprising, although the difference between distance and on campus respondents is relatively small in this case.

A recent study at CSU of distance student use of technology including virtual lectures and asynchronous forums and grades found that the more the students engage with these online resources the greater their academic achievement (Crampton, Ragusa & Cavanagh, 2012). The authors noted that it was perhaps the students who realised the value of the resources, students perhaps with higher self regulation skills, who were more likely to engage with the resources and that development of student led regulation/ self directed leaning skills should be included early in a students' academic career (Crampton, Ragusa & Cavanagh, 2012).

The desire for an increase in the use of online marking and quizzes (see Table 4) was consistent with internal subject evaluations in which students continued to request improved mechanisms of feedback. Quizzes and online marking promote self directed study as well as facilitating the return of feedback during the session, at a time that is maybe most productive for improving learning. CSU's large contingent of distance students for whom the practical realities of their sometimes very remote locations can prevent the timely return of some assessment items. Therefore it could be argued that just as educators are starting to see technology as a means of addressing existing barriers rather than just a call by some to totally change how they teach, so too students are beginning to understand the role technology can play in improving experiences they currently value such as feedback in a more appropriate and useful manner.

It is important to note that apart from the use of the subject outline tool and the discussion forum, there are no mandatory requirements for any particular educational technology to be used in any class at CSU. For some aspects of this survey (such as Table 4 which displays results of students' actual-versus-desired use of particular technologies) results may be skewed due to the possible lack of student experience of a particular tool. For example, it may be difficult for a student to determine that they would like to use more blogs or wikis in their class interactions if they have little or irregular experience of these tools, especially in this context. As most students indicated they wait for others to take the lead in terms of new technologies (see Figure 1), it is difficult to know to what extent we need to further adopt such technologies on this basis alone. Apart from communication and administrative functions (email, chat, resources, etc), and tools that enable students to study in ways that enable them to work their study commitments around work and family obligations, it may be assumed that technologies should still be chosen for their pedagogical benefits, rather than student desire alone.

Looking forward, we see the emergence of more mobile learning initiatives and strategies and would suggest that institutions learn from past blind forays into LMS. Important questions that need to be asked are "what gap/s will be addressed by such technologies?", "what are student needs?" and "what pedagogical affordances will mobile learning address?". Our results would suggest that space and opportunity to explore need to be provided to staff and students as a first step down any new paths so that increasingly limited resources can be channelled in the most effective ways rather than be driven by the technically savvy early adopters.

A matrix for sustainable online community development

Susan Tull
e-Learning Lab
University of Canterbury

In supporting the development of an online community of practice, the uniqueness of a community and its situation need to be recognised in both its design and growth. The matrix outlined in this paper and poster draws from both guidelines and frameworks in the literature, and the study of one developing online community of practice. The perspective it provides will be of particular value to those seeking to grow and sustain an online community of practice, for a relatively small community of educators.

Online community, Matrix, Framework, Design, Community of practice, Adult education

Designing for an online community

An online community of practice (OCoP) for professional development has much to offer. In designing and creating such an environment Stuckey and Barab (2007) note that a "community-based approach holds great promise for learning, as it does not simply support content acquisition but is focussed on transforming practices ... by putting the power of this transformation in the actions of its members" (p.443). Developing an OCoP, however, requires careful consideration and planning, and takes time and attention to implement and grow (Stuckey & Barab, 2007). As stated often in the literature, a community of practice cannot be designed, but it can be designed for.

In creating an environment for an online community, the community itself needs to be considered. While focussing on design for online learning communities Riel and Polin (2004)explain that, "a community differs from a mere collection of people by the strength and depth of the culture it is able to establish and which in turn supports group activity and cohesion" (p.18). It is a combination of the environment, community members, and the activities which they undertake within it, which help to create a community. The activities in which a community involves its members need to be meaningful and linked to their practice. As Schlager and Fusco (2003) found, "simply having the ability to interact more frequently and for longer durations online than face-to-face does not translate directly into high-quality learning experiences or sustainable communities" (p.127). Not all efforts to create an online of community of practice for teachers have been successful. Schlager and Fusco (2003) also observed that "few professional development projects … resulted in online communities … sustainable enough to support teachers as they engage in the extended process of classroom reform" (p.127). Schwen and Hara's (2003) research observations and review of CoP literature reported that none of the fully functioning CoPs in their study had been designed. All had evolved naturally over several years.

The apt analogy of plant growth has been used for community development. Designing for an OCoP for one organisation's distributed community of adult educators was akin to preparing the soil and planting the seeds. From its beginnings, this OCoP, like a living entity, continued to change. Stuckey and Barab (2007) explain that a community is "continually evolving according to the relationships between members and the maturing practices of the community" (p.441). There are many conditions which need to be considered in designing for a community, and these must be kept in balance for healthy growth to take place. The matrix in this poster paper outlines the different elements needed by this community as it grew through the phases in its development.

A matrix of elements for developing online communities

As Stuckey and Barab (2007) point out, "No one who has tried to develop a Web-supported community in the service of learning could deny the challenges in doing so" (p.456). However, there are some helpful examples, frameworks and guidelines available in the literature. Riel and Polin (2004) structure their view of the community through the four dimensions of; membership, task features and learning goals, participation structures, and mechanisms for further growth and reproduction. In her meta-analysis of guidelines Stuckey (2004) uses Hillery's (1955) four common components of community; common ties, people, social interaction and place. Preece (2001) offers purpose, people and policy as the three design criteria for sociability and dialogue and social support, information design, navigation, and access as the four design criteria for usability. In developing the matrix from this study, all these dimensions/components/criteria have been combined to form three components of the online community, namely Environment, Engagement and Stakeholders.

Each of these components is considered in terms of the elements which have encouraged the development of the online community within the three phases of this study. These phases loosely align with what Stuckey (2004) calls "areas of influence and action", where the developers seek to design, implement and sustain the community. Elements within the full matrix are drawn both from the literature and from the study of the design, implementation and growth of the online community designed for the organisation of adult educators. Following an initial coding of the data using constant comparison to distil grounded theory on the elements of the community's development, the data was re-coded using the elements of Stuckey's (2004) meta-analysis. This re-coding highlighted existing elements of Stuckey's framework which were relevant, and some which were not appropriate for this community, as well as new elements distinct to this community's development. From this a matrix of elements for developing an online community relevant to a distributed single organisation's OCoP was created. The community specific elements contributed to the framework by this research are displayed in Table 1 and the full matrix can be viewed in the poster.

Table 1: Summary of additional community specific elements

	Environment	Engagement	Stakeholders
Sustain	*Maintain flexibility of design	*Maintain the value added	*Encourage more community members to provide leadership, impetus, and inspiration *Encourage members to run subgroups
implement	*Be open to community input *Develop both whole community and small group spaces	*Highlight the value added *Keep it relevant to the professional practice *Encourage a critical mass of engagement *Provide the means for collaboration to take place *Encourage member connections through communication and community awareness *Create new rituals	*Find well respected community members to provide coordination, leadership, impetus, and inspiration
Design	*Situate the community in the practice *Fulfil existing community needs *Design with simplicity *Ensure appropriate IT infrastructure is in place	*Keep it relevant to the professional practice *Develop connections	

While all components; environment, engagement and stakeholders, needed to be considered throughout the community's development, the emphasis of the developer activity fell on different components as the community developed through the phases. The environment was most important during the design phase. In the implementation phase, engagement was most important and in the sustain phase, the emphasis moved to the stakeholders. Because the community in this study is comparatively young and still very much under development, some of the elements in the sustain phase are still to be verified. These elements are based on data of what has sustained the community so far, and the missing elements which may be holding it back from further growth. The matrix as a whole should provide focussed support for community development in a similar context, throughout the design and implementation phases and on towards sustainability.

Understanding novice programmers: their perceptions and motivations

Kylie Turville
University of Ballarat

Grant Meredith
University of Ballarat

Philip Smith
University of Ballarat

This paper presents the initial findings of an ongoing research program eliciting a basic understanding of students undertaking a first year programming course at the University of Ballarat, with a particular focus on their motivations and aspirations. This paper also provides a brief history of the course within its institutional setting including the different strategies that have been implemented over the last decade, an overview of the overarching study that is currently being undertaken, a discussion of some of the initial results, as well as a short discussion further research that is currently being undertaken. Results from the initial study indicate that students are positive coming into our courses but can become disillusioned as the course progresses. The research path forward will also be presented along with the discussion of these initial findings.

Keywords: Novice programming, motivation, perceptions

Introduction

Programming is a proven difficult topic to learn and teach and there is a great wealth of research attesting to this (Bergin, Reilly, & Traynor, 2005; Bonar & Soloway, 1983; Lewandowski, Gutschow, McCartney, Sanders, & Shinners-Kennedy, 2005; Lister et al., 2004). In spite of the effort dedicated to understanding and resolving this problem, IT programs and courses, including our own, are still suffering high attrition, failure and dropout rates (Ramalingam, LaBelle, & Wiedenbeck, 2004; Roberts, McGill, & Hyland, 2012). This situation is made even more perplexing by the perceived shortage of IT professionals in the work force (Barnes, Powell, Chaffin, & Lipford, 2008).

Like many others educational institutions, we have been experiencing on going challenges delivering introductory programming courses to commencing first year students (Bonar & Soloway, 1983; Lewandowski et al., 2005; Lister et al., 2004; Nagappan et al., 2003). In order to better understand the perceptions, motivations, aspirations and concerns the students have when they undertake our degree we planned and deployed a series of surveys throughout the first 2012 semester of a first year programming course. We endeavoured to discover if the students have any pre-existing programming knowledge, what motivates the students to undertake the course, and whether their motivations fluctuate during the lifespan of the course.

This paper provides a brief overview of the history of our programs and the first programming course that most of our students are required to undertake, and discusses some findings of interest from the first exploratory survey that was conducted prior to the students' first programming class. The students' responses to the various questions were in general very positive indicating that, at this initial stage, many of them perceived programming to be both achievable and relevant to their career goals.

Background

The University of Ballarat (UB) is a small, regional university located approximately 100 km northwest of Melbourne, Australia. UB draws a range of domestic students mainly from Western Victoria, and they tend to have a wide variety of backgrounds and abilities. Many of our students come from circumstances that fit them into one of our so-called "equity groups" which indicate disadvantage – for example, many come from sparsely populated areas that have limited access to certain resources such as broadband Internet, or at times may be the first on their families to attempt tertiary education. Some have not had great success in their secondary studies, may come from low socio-economic backgrounds and in turn face many challenges in undertaking tertiary study (Devlin, 2010; University of Ballarat, 2011). A further complication that we are currently facing is the emergence of a demand driven intake which has resulted in a far wider range of students that has been encountered by UB to instruct, support and assess.

ITECH1000 Programming 1, SITEs CS1 course, is a core course within many UB degrees including the Associate Degree, all the undergraduate IT degrees delivered by SITE, the Bachelor of Mathematical Sciences, in most of our conversion Masters degrees and the course is also offered by most of our partners. Students enter our degrees through a variety of means including students with ATAR scores, direct entry, students articulating from TAFE, students who have completed our Foundation Access Studies Program (FAST), mature aged students, along with international students from a variety of countries and educational backgrounds. This diverse, mix of students has made the shaping and delivery of courses to be a continually challenging and evolving process within SITE.

Since 2001 ITECH1000 has undergone a significant number of structural and pedagogical changes following the trends of many other universities and lines of research (Barnes et al., 2008; Koffman & Wolz, 1999; Smith & Boyd, 2001). During this time the school also developed a number of partnerships with private providers; as a consequence, the programming course underwent further changes to internationalise the content of the courses and to accommodate a wider variety of commencing student types. The course also had to be developed in such a way that it could be delivered as a standalone package to enable partner lecturers to deliver the material successfully and without further development. Adding to this momentum of change was the school adopted policy of providing students with early feedback within all first year courses. This process of early intervention enabled students who were struggling with the course to be given an opportunity to seek personalised assistance early and in turn raise their chances of successful course completion.

Like many other universities we also utilised a number of other evolving and differing approaches to aid student learning. These approaches have included, but are not limited to, the use pair-programming within the laboratories (Nagappan et al., 2003), using exercises to challenge high-achieving students who were becoming disengaged, using robots to enable program visualization (Wu, Tseng, & Huang, 2008), and implementing a Peer Assisted Study Scheme (PASS) to provide further assistance to students (Devey & Carbone, 2011). Nonetheless students continue to have difficulties.

It has become apparent that we now need to focus on the demographics, needs, motivations and expectations of the students involved. The first step towards this new approach was to develop an understanding of the backgrounds, motivations and perceptions of the new students entering the course. We also intend to study how these factors change for the student during the lifespan of the course.

The Study

The purpose of the main study was to develop an understanding of the students undertaking the first programming course in our IT degrees, focusing on the motivations and perceptions of these students. A series of exploratory surveys were planned over the semester including prior to the students first lecture, the mid-point of the semester (week 6 of 12), and in the final week of learning (week 12).

This paper focuses on the data collected prior to the first lecture in week 1 of the first 2012 semester and contained a series of questions covering demographic data, perceptions of programming, issues regarding the commencement of programming, prior programming experience, students' thoughts regarding how they would approach the course, and the final result the student expects to obtain for the course.

Further data was collected throughout the semester to provide a comparison with the students' initial responses, focusing on their perceptions of success or failure within the course, how their view of what programming is changes and where they will seek assistance. This data is continuing to be gathered and analysed for future publications and presentations. In the following section we provide a description of the participants of the survey, an overview of the initial data that has been collected and how the data has been analysed.

Results

Participants and Data Collection

The participants are fifty eight (N=58) students who were enrolled in ITECH1000 Programming 1 which, as outlined earlier, is the first programming course taught within a number of degree programs at the University of Ballarat and is generally a core, unavoidable course for most enrolled students. The course may also be taken as an elective by other students at the University but in general this is a rare occurrence. The data collected was analysed using Minitab. Descriptive analysis was conducted using Pearson Chi-squared tests and basic thematic analysis was used to model trends.

Participants – Demographics

The majority of the students who participated in the study were under twenty (20) years of age (72.4%). The cohort was predominantly male (82.8%) and there were only small number of international students who took part in the initial survey (13.8%). Over half of the students entering the course have had some form of prior programming experience (58.6%). The languages previously used by the students varied. Most of the previous experience was completed within a formal school setting, however, a small percentage (8.3%) were self-taught.

We also asked the students why they were undertaking the degree. Most of the students indicated that they were enrolled as they wanted to become an IT professional, with second most common response was that they enjoy working with computers. Surprisingly and encouragingly there were indications that the surveyed cohort had entered our degree and introductory courses with a very solid pre-understanding of the concept and meaning of programming. The students generally expressed a detailed view of what programming meant in terms of: different languages that could be used; automation of processes; the building of applications to solve problems and a multi-industry view point of use. Although interestingly a small number of students who answered this question seemed to confuse scripting with programming. Even more surprising was the consistently solid understanding of what programming entailed. These themes include the likes of: having to apply different languages; continual learning; testing and debugging; and the use of multiple platforms.

None of the students who completed the survey expected to fail the course, with the majority of the students expecting to receive a final grade of HD (33.3%) or D (42.11%). Only four of the respondents expected to receive a final grade of P (7.0%). Due to the low numbers of respondents who indicated that they would receive a C or P grading (N<9), the data for these two categories was combined for the purposes of the analysis.

Expected Results

A Pearson Chi-square test was run to investigate whether there is a relationship between gender and expected final grade. The results indicate that there was not a significant relationship between the gender and expected final grade (see Table1: Gender and Expected Result).

Table 1: Gender and Expected Result

	M	F	All
HD	15	5	20
	70.00	55.56	34.48
D	22	2	24
	44.90	22.22	41.38
C/P	12	2	14
	24.49	22.22	24.14
All	49	9	58
	100.00	100.00	100.00

A Pearson Chi-square test was also run to investigate whether there was a relationship between prior programming experience and expected final grade. The results indicate that there was a significant relationship between the prior programming experience and expected final grade. By examining the table below overall students with prior experience expect to get a higher grade and those without experience lower, this is evidenced by 71.43% of the students with no prior experience expecting to get a C/P grade (Chi-square = 6.920, DF = 2, p-value = 0.031; see Table2: Prior Programming Experience and Expected Grade).

Table 2: Prior Programming Experience and Expected Grade

	Yes	No	All
HD	14	6	20
	70.00	30.00	100.00
D	16	9	24
	66.67	33.33	100
C/P	4	10	14
	28.57	71.43	100.00

All	34	24	58
	58.62	41.38	100.00

Future Directions and Conclusion

We wish to draw what conclusions we can about first year student motivations and pre-existing programming knowledge in order to better prepare materials and shape pedagogical practise. Our ultimate aim is to improve student performance (i.e. grades) without adversely affecting learning outcomes or diluting course content. We especially want to reduce the number of failures and dropouts which are so problematic to a small teaching institution in a competitive environment. We have anecdotal evidence that some students in the past have changed degrees or have dropped out of tertiary study based upon not being able to successfully pass the introductory programming course on their first attempt.

Once we have completed the whole series surveys we will match it up with other sources of data such as attendance records (at labs and lectures), and final grades. We will examine the access of Moodle (our electronic repository for materials) to see whether students are finding more flexible ways to learn the material. We will also examine any exit interviews provided by students who do drop out although these are not always available.

We then expect to expand our studies to our partner institutions who are also concerned about failure and dropout rates. These students differ in demographics from those at our Mt Helen campus in that they are mainly international students. We would expect these students to have a different set if backgrounds, concerns and motivations from those of our domestic students. We will also conduct surveys with our Programming 2 (CS2) students and students in more advanced courses to how motivations have changed during the course of their degrees.

This initial survey into various perceptions, motivations and concerns of students commencing our CS1 course (Programming 1) was an exploratory survey conducted in response to concerns of high failure and dropout rates of students in these early core courses. We found students, in general, have very positive attitudes towards their new course, expect to do very well and have a firm entering understanding about what programming means and entails. Many of them had very explicit ideas of what careers they wished to pursue once they finish their degree which indicates an intrinsic motivation towards their studies. Follow up studies will attempt to elicit if and when these motivations change and will be used to find possible remedies for this problem.

ANU Campus Quest: A Mobile App For Transition

Jodi Tutty
Academic Skills and Learning Centre
Australian National University

Sage Leslie-McCarthy
Academic Skills and Learning Centre
Australian National University

This paper outlines a new mobile application designed to assist student transition at the Australian National University (ANU). It briefly outlines the importance of addressing student transition in the current higher education climate, and explains why the ANU has decided to move into the mobile space in order to assist student transition to the geographical, social and institutional context of the university. The app is designed as an information-based scavenger hunt, informed by research into the social and learning utility of games. Students need to work in teams to devise strategies to approach the game, assisting them to make social connections, while the game itself takes students across campus to discover spaces and university cultures.

Keywords: transition, gamification, mobile apps

Introduction

Transition to university is a significant issue for higher education institutions, emphasised by the increasing social, cultural and academic diversity present in the incoming student cohorts. This diversity is likely to increase following the release of the Bradley report which recommended widening participation to increasingly include non-traditional students from low socio-economic backgrounds, equity groups and mature age students (Bradley, Noonan, Nugent & Scales, 2008). Not surprisingly, these students exhibit diversity in terms of existing academic knowledge and are managing a variety of work/life balances. To accommodate these differences, universities have responded by offering more flexible study patterns such as different times of entry (mid year etc), different modes of study (distance, face to face, online etc) and part time study. All this increases the challenges in managing successful student transition to university (Johnston, 2010; Kift, 2009).

This paper outlines the rationale for and design aspects of a new mobile application (app) designed to assist student transition at the ANU. It focuses on the decision to utilise the mobile space, explains why the app is designed as a game, and outlines the key features of the app including the need for students to work in teams, form strategies and physically engage with the campus itself.

The need to address student transition

Holistic approaches to transition are needed that recognise a wide range of transition issues including cultural and community, academic, social and personal elements (Johnston, 2010). These approaches, dubbed as third generational approaches (Kift, 2009), are essential as the more socially and academically engaged the students the greater their persistence (Tinto, 2009). Establishing firm social networks is a crucial aspect in student retention (Christensen & Evamy, 2011) with Willcox, Winn and Fyvie-Gauld (2005) finding in their small study that the lack of friends was a significant factor in student withdrawals. One focus of transition is the first few weeks of a new student's university life as it can involve great emotional and social upheaval. Students "have an urgent need to belong, to identify with others, to find a safe place and to negotiate their new identities as university students" (Willcox *et al.,* 2005). Making initial contacts with others is important in helping students adapt to university life. Transition activities need to provide opportunities for students to do this as well as orienting them to campus and academic life.

ANU is developing a more holistic approach to transition. One of the initiatives that forms part of this wider program is a mobile application for Orientation week that aims to start students on their journey to engage with the university. Specifically the app aims to:

- geographically orient students to the campus
- encourage students to socially connect with their peers
- introduce students to the institutional structure.

Why a mobile app for transition?

Smartphones are becoming ubiquitous. Already, Johnson, Smith, Willis, Levine, & Haywood. (2011 p.13) estimates that “virtually 100% of university students worldwide have mobiles”. Increasingly these phones are smart devices capable of connecting to the Internet, and 62% of smartphone users downloaded an app in the last 30 days (Neilsen, 2011). This uptake of smart mobile devices is predicted to continue with 80% of access to the Internet by 2015 to be via mobile devices (Ericsson as cited in Johnson *et al.*, 2011). This strongly suggests that smartphones are a medium that will become increasingly important in the tertiary education environment.

However, despite these figures, the impact of mobile devices and other Web 2.0 tools on university learning is open to question. Some such as Prensky (2001) and Brown (2002) coined the term digital natives to describe the generation brought up with the Internet, and contend that this group learns in fundamentally different ways to older generations. To engage this cohort, they argued new approaches to learning were essential. Increasingly this is being challenged as the wide diversity in IT skills and associated learning approaches among university students is recognised (Kennedy, Judd, Churchward, Gray & Krause, 2008; Lorenzo, Oblinger & Dziuban. 2006). Notwithstanding these differences, technology use is escalating and students increasingly have expectations of “access, convenience and connectedness” (Kennedy et al. 2008, p.118). In this increasingly connected world, both the university and students need to become competent and engaged users of the technology.

In this context, creating a mobile app for transition was a logical choice. Mobile apps are popular and this was one way of seeking student involvement at a time when a lot of things are competing for their attention. It was also an authentic use of the technology that fitted well with encouraging greater use of appropriate technology in the university context. Smartphones offer portability, location detection (knowing where they are) and image capture (Johnson *et al.,* 2011), all necessary features for the orientation app. Finally, while not all students would have smartphones, the use of teams in the orientation activity would ensure all students could participate.

Why make the app a game?

Our orientation activity needed to encourage social interaction and engagement with the university; it needed to do more than provide information. To this end, the app incorporates a game-based approach as this is capable of both encouraging social interaction and facilitating engagement.

Social interaction and cooperation with other players are powerful attractions of a game. This is reflected in social games such as *Farmville* or *World of Warcraft* where competition is still often an important element of a game but not the overriding reason to participate. In team games, more players are motivated to participate than if they are only competing for themselves (Zicherman & Cunningham, 2011). If students are motivated to work together to achieve team goals they are conceivably more likely to engage interpersonally with their team members and to begin the process of social transition to the university.

Similarly, games can be a powerful tool to increase a person’s engagement in tasks that might not have interested them. Kapp (2012) gives the example of a subway station where the exit stairway was changed so each step played a musical note when stepped on by a commuter. As a result, the use of stairways over the escalator increased by 66%. Fun, an essential element of games, not health concerns made commuters engage and change their behaviour. In the transition context, many students attend the campus during orientation week but anecdotal evidence suggests they often do not wander far from the commercial hub of the campus, or get a feel for the campus as a whole. Reasons for this include the lack of motivation to do so, or the fact that such exploration may not be as exciting as other socially-based orientation activities. On a campus such as the ANU which is geographically large, it is important that students begin to find ways of coming to terms with and navigating this vast physical space. This is encouraged by giving students a fun and social reason to start exploring the campus.

The ANU Campus Quest app

The Campus Quest app is designed as an information-based scavenger hunt to be undertaken during Orientation Week. Students will be organised into teams to complete a number of activities. Activities fall into 3 broad categories: multiple-choice questions, alphanumeric questions requiring the entry of a correct response, and image questions that require students to use their phones to take a photo of a particular thing, the GPS coordinates of the image then being verified with the coordinate range of the correct location (see Figure 1). The points awarded for an activity depend on its difficulty. At the start of the hunt, teams will be given some time and campus maps (print or electronic) to plan and strategise. Through the app, activities can be assigned to members. Teams then break up and spread across campus to answer activities. Team progress can be seen throughout the hunt. Activities are not marked until the end, to give students an opportunity to discuss and alter their responses throughout the challenge. To avoid last minute guessing of multiple choice questions, points will be deducted for incorrect answers. At the completion of the quest, the team with the most points will be announced the winners and awarded a real-world prize.

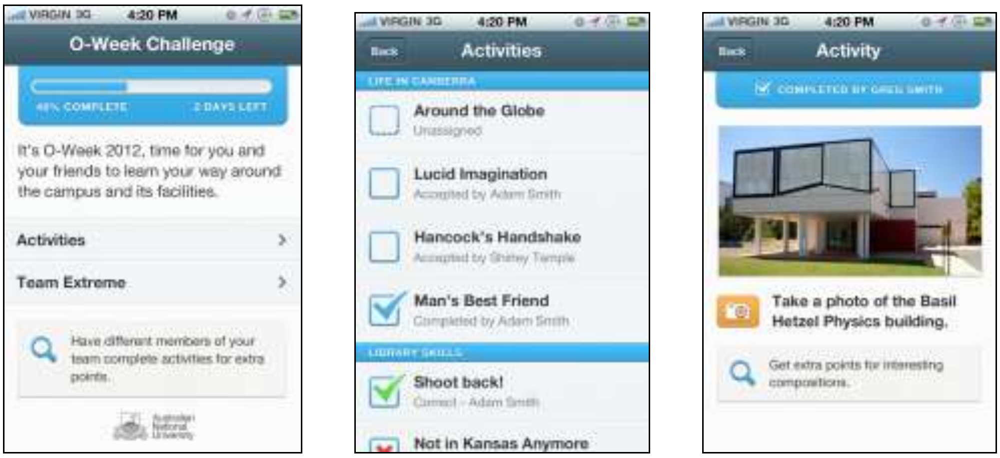

Figure 1: Three screen shots showing the screen for Team Extreme, the list of activities, and an activity. The list of activities shows who has been assigned an activity and if it has been answered.

The app has been designed to meet three aims: to encourage students to socially connect with their peers, geographically orient students to the campus and introduce students to the institutional structure. To encourage social interaction, the game requires significant collaboration between team members. Students register as individuals and then will be broken into teams so they will have the opportunity to meet new people. The app allows for the number of people per team to be greater than the number of phones; for example a team of 10 students will only be allowed a maximum of 5 phones. Thus, students will have to work in small groups to go around campus to complete the activities and will also have to coordinate and form strategies with other team members to allocate tasks. Extra points will be awarded to the teams that spread the tasks most evenly amongst themselves. This will be measured by how many activities each 'phone' completes and the spread of completion across the team.

Each activity is designed to help students orient themselves to the physical environment or institutional context of the university. For example, students may be given a photo of a small part of a building and asked to identify it, or be asked to obtain a key piece of information from the plaque of one of the many statues around campus. Other activities focus on places to eat and exercise, and may ask students to obtain prices of coffee or gym membership. Still other activities focus on how the university works, and ask questions about, for example, the college structure or university motto which can be obtained by navigating the university's website - familiarising students with this important resource.

To succeed in its aims, the scavenger hunt must be fun. Game designers aim to get players into a state of flow or 'in the zone' (Zicherman & Cunningham, 2011). Flow is a state between anxiety, where the task is too difficult and stressful, and boredom where the task is repetitive and unengaging. When designing activities for the game it was therefore important for us to consider the fact that activities that could conceivably meet the transition goals (for example asking questions about course rules and university regulations) may not necessarily enhance student engagement with the game. Additionally, the activities need to be challenging but doable and not repetitive if we want to maintain engagement, hence we needed a range of challenges from easy to difficult. Rewards help to keep players in a state of flow. Surprisingly, rewards that are not predictable in their occurrence or size are often the most effective (Zicherman & Cunningham, 2011). We have tried to build in some unpredictability of rewards with hard challenges where there is no certainty of success.

Similarly, a recognition that not all students are sophisticated users of technology means that the app only requires them to employ the basic functions of their phones. Thus tools such as Foursquare (https://foursquare.com/), that require downloads or even tools such as QR codes (http://www.denso-wave.com/qrcode/index-e.html) that require a more sophisticated use of technology were avoided. However, this may change in later iterations. The app is capable of working on both Apple iPhones and Android phones.

Finally, the app was designed for both large numbers and flexibility. To facilitate large numbers, all activities are machine verifiable. Thus winners are available as soon as the quest is over. Later iterations may include new types of activities that may require human verification, such as the taking of photos of 'favourite' or 'quirky' locations on campus. Flexibility is incorporated by not limiting the number of activities, size of teams, length of quests, or content of activities. It is hoped that this will eventually allow the app to be used for a wide range of situations and groups.

The app will be piloted during July 2012 before being rolled out for O week 2013. Pilots are planned both with a group of postgraduate students involved in a mid-year intensive program and with new undergraduate students as part of the orientation activities for Semester Two. The pilot sessions will give teams twenty minutes to work out their strategies before having a two hour quest window. Feedback on aspects of useability and experience will be gathered from the pilots.

For orientation 2013, the quest will be open to all new students. We plan to run quests tailored to individual academic areas. This will not only allow students to meet new people studying similar courses but allow us to tailor activities more appropriately (e.g. send law students to law locations etc). Depending on the feedback from the pilot, we may also look at running different length quests or themed quests, e.g. history of the campus.

Conclusion

Though this app is still in the pilot stage it is envisaged that a game-based design that encourages social interaction and campus exploration while assisting students to learn more about the university itself and its culture will assist students to begin their transition process at the ANU. It may not suit all students, nor is it by itself the solution to transition issues. Rather it needs to be one part of an integrated package.

While this app has been designed with O week in mind, it has the potential to be used much more widely. It is suitable for many groups new to the university, e.g. school groups, short courses etc. Similarly the generic nature of the activities may allow the quests to be expanded beyond orientation to more academic content.

Breaking the Rules: Supporting Learning and Teaching Technology Innovations

Philip M. Uys
Division of Learning and Teaching Services
Charles Sturt University

Cathy Gunn
Centre for Academic Development
The University of Auckland

The learning and teaching landscape in higher education fails to actively support innovators to experiment with new technologies and educational methods. It is also a poor provider of ongoing support for innovations after start up funding runs out. There are tensions between enterprise systems and 'grass roots' initiatives in a context where technology is changing rapidly and institutions are slow to respond. Innovators in learning and teaching using emergent technologies are often treated as suspects in an undefined crime. They are pushing boundaries... and bureaucratic institutional buttons! Charles Sturt University (CSU) took an unprecedented step to break these punitive rules of engagement with an institutional Learning and Teaching through Technology Innovation Support Service (LATISS). The LATISS is described within the framework of a four phase learning and teaching with technology innovation (FPLTI) management model, and offered to other institutions of higher education as a means to foster innovation.

Keywords: innovation; educational technology; learning; teaching; rules; sustain; institutional impact

Introduction

Innovators in learning and teaching using educational technologies are often treated as suspects of an undefined crime (Discussions at ACODE 57, 2011). They are pushing boundaries... and therefore also bureaucratic institutional buttons. Charles Sturt University took the unprecedented step to break the rules of engagement to actively support innovators using educational technology through the Learning and Teaching Innovation Support Service (LATISS). The institution takes a positive stance on academics using external technologies, and the first author is currently leading a group to develop guidelines for their use within the institutional environment.

An innovation management model with distinct but overlapping phases of support has emerged from practice at Charles Sturt University and from the literature. The result is a four-phase learning and teaching with technology innovation (FPLTI) management model. Phase one encourages and supports innovation and experimentation, through strategies like LATISS. Staff are encouraged to try new learning design approaches and technologies within a scaffolded framework, and without too much concern for the risk of making mistakes. Phase One is the focus of this paper in which LATISS play a key role. Phase Two involves analysing the educational potential of the innovation for niche or wider applicability at the university, while Phase Three leads to University support for dissemination and adaptation of the innovation for use in different contexts. Phase Four deals with the critical activity of sustaining the innovation through a projected lifecycle that makes optimum use of the available potential.

LATISS has been conceptualised and implemented within the broader framework of learning and teaching innovations in higher education. Experience at Charles Sturt University and research conducted in the wider context of the international higher education sector provides the theoretical basis for design of this support model.

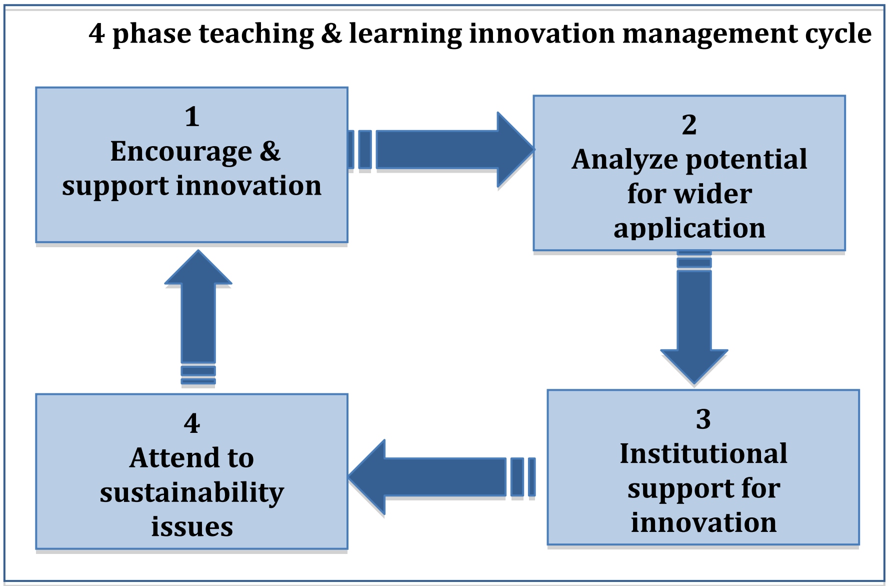

Figure 1: The FPLTI management model.

The challenges of supporting learning and teaching innovation

The challenges associated with learning and teaching innovation in higher education are not new. Earlier research explored the motives and drivers behind innovations involving new technology, and identified different sets of challenges and opportunities associated with top down versus individually driven initiatives. Hannan, English & Silver (1999) drew on interviews with 221 staff from 15 UK universities to acknowledge a range of punitive effects on lone innovators, despite the existence of institutional strategies that espoused their support. As noted above, these innovators are often treated as suspects in an unspecified crime as they challenge tradition in disciplines and institutions, and thus put personal career progression prospects at risk. This is hardly a just 'sentence' for creative attempts to leverage new technology to enhance student learning, accommodate larger and more diverse groups of learners, and meet demand from the professions for actively engaged and broadly educated graduates. Indeed, it is a testament to the commitment of the individuals concerned that innovation happens at all.

The tendency of top down initiatives to seek a 'one size fits all' solution has been found equally detrimental to the instantiation and spread of innovations. Gibbs & Gosper (2006) criticized the 'narrow view of education and pedagogically weak designs' reflected by the capabilities of the current generation of institutional elearning systems. They found the common practice of developing strategy at the centre, without broad consultation, resulted in low practitioner involvement. Hannan, English & Silver (1999) had already found teaching and learning support units struggling to implement centrally driven strategies that defined the direction, if not the actual form, that innovation should take.

A more recent study of 22 high profile elearning innovations from the Australasian higher education sector identified similar barriers in the structures and processes of the institutions that espouse their support (Gunn & Herrick 2012). On the technical side, centralized IT Services models are not set up to promote experimentation with emergent elearning tools, and pedagogical strategies are often (though not always) perceived to be constrained by the capabilities of the LMS. Common administrative tools provided by the LMS meet most faculty needs, but the 'art' of learning design demands greater flexibility and user choice. It is not, of course, reasonable to expect a central service department to be equipped to support every choice a creative teacher or adventurous learner might make.

The root of the problem can be traced to tensions arising from the interaction of new technologies with new sets of circumstances against a backdrop of institutional traditions (e.g. established ways of teaching and leading from the top) and constraints (e.g. resource limitations and enacted priorities). Various authors have defined the conditions required to support elearning innovations, (e.g. Alexander 2001; Southwell et al 2005; Stansfield et al 2009: Gunn 2011). These differ considerably from the conditions found in many contemporary universities, and are summarized as follows:

- A vision for elearning at the institution
- A culture that supports teaching and learning innovation, collaboration and risk taking
- Faculty development opportunities in learning design, project management, teamwork and evaluation
- Faculty workload policies that accommodate elearning, e.g. with time release for development
- A comprehensive technology plan, maintenance of reliable technology networks, and facilities to provide technical support to staff and students

These high level statements translate into different realties in particular institutional contexts. However, a recent study involving a group of individual elearning innovators found very few situations where all these conditions were present in their professional practice context (Gunn 2010b). Another issue here are the 'significant shortcomings in the capability of senior management teams in HEIs to identify and exploit the full strategic potential of technology' reported by Duke, Jordan & Powell (2008). Unfounded speculation and failed expectations of the impact of new technologies on higher education (e.g. Zemsky & Massy 2004) make it a hard task to gain high level commitment and to encourage other faculty to follow the road marked out by pioneers (Hannan, English & Silver 1999). So scenarios where individual innovators struggle for recognition and strategic initiatives fail to gain traction remain all too common in the university sector. A workable solution is required so the espoused institutional intention to support teaching and learning innovation can be realized. Better business intelligence to inform management decisions would be an integral part of that solution, and wider consultation is one sure way this could be achieved.

From an institutional perspective, some degree of standardization and constraint must be applied for budgets and support service provision to remain feasible. However, the trick is finding a balance that will support rather than stifle innovation, and allow the experience of exploratory work at grass roots level to inform later developments and influence strategic initiatives. This implies a staged approach to support for different types of innovations. Kelly (2006) provides an example where exploratory, developmental and validation phases take place within an educational design research cycle. Nieveen, McKenney & van den Akker (2006) note the predominant focus of published literature on validation studies. This could be explained as a result of the types of research that are acceptable for publication. Whatever the cause, it creates a communication gap that is unhelpful for individuals or institutions seeking to learn through shared experience and discussion of ideas at the exploratory or developmental stages. The most accessible place to begin to address this gap may be at institutional level, where attempts can be made to define the kind of support that innovators need and that central services can reasonably provide.

While innovation and user choice need to be encouraged, at least in the early stages, there are clear benefits from situating these opportunities within an institutional framework that shifts the perception of innovators as outlaws, and provides a reasonable level of support for exploratory work. Ideally, this would make the best expertise from across the institution accessible to innovators, foster broad collaboration, and keep central services such as Teaching and Learning Development and IT departments engaged with emergent trends (Gunn 2010b). Diffusion of leadership roles and responsibilities around elearning innovation could also be facilitated through a networked approach. As far as the literature is concerned, the challenge of defining such a framework has yet to be resolved, and the need for discussion and dissemination of ideas among innovators, teaching staff and managers remains largely neglected. The affordances of social networking technology offer the means to address these issues in a practical, inclusive and affordable way. The challenge lies in shifting institutional culture and practice to actively support what the technology affords, and in the process, turn innovators from suspects to star witnesses and key informants.

From suspect to star witness

The problems facing teaching and learning innovators and institutions are well documented, and provide a sound basis on which to build a supportive institutional framework (Stansfield et al 2009; Gunn 2010a&b). In general the learning and teaching innovation landscape in higher education can be characterized as:

- Lacking active support for innovation and experimentation
- Failing to provide ongoing support for innovators after initial funding rounds
- Lacking transparency and consultation around decisions on technology for teaching and learning
- Responding slowly to rapid advances in technology
- Espousing rather than enacting values around elearning innovation

- Creating tensions between enterprise systems and ‘grass roots’ initiatives
- Failing to acknowledge the different phases of innovation, i.e. exploratory, validation, dissemination

While broader action is needed to address many of these deficiencies, the LATISS was conceived to address the first two issues listed above.

Advancing innovation at Charles Sturt University

In the past, the Charles Sturt University innovation landscape included a number of institutional players, but support mostly occurred in formal and selective ways. A Flexible Learning Institute supported small-scale innovations, and developed ‘self help’ resources relevant to the institutional community for both small and large-scale initiatives. Further support was available through colleagues in faculties or schools, such as a fellow champion, Sub-Dean Learning and Teaching, Head of School or Learning and Teaching committee members.

LATISS was conceived by the Strategic Learning and Teaching Innovation section in the Division of Learning and Teaching Services so innovators could share what they are doing, and if required, be supported by the Information and Communication Enables Learning community of practice that has just over 650 members. This community uses Yammer, a microblogging tool, to share information and request support. The rationale for LATISS includes the beliefs that: a) to remain competitive in an open Educational Market, Charles Sturt University must create an environment supportive of learning and teaching innovation using technology; b) without this kind of innovation the University will be a perpetual follower - not an innovator; c) smaller learning and teaching innovations and experiments with new technology that happen outside the scope of projects are often valuable but not supported; and d) support should be provided for distinctive applications of educational technology in specific areas and possibly with small groups of students.

Larger scale innovation is supported at Charles Sturt University in a number of ways. Plans for new or updated educational technologies for a significant segment of Charles Sturt University can be discussed with the Executive team, Strategic Learning and Teaching Innovation or Educational Design and Media sections of the Division of Learning and Teaching Services . Proposals ultimately go to the Curriculum, Learning & Teaching Committee and the Information and Learning Systems Committee for consideration. The Flexible Learning Institute’s Teaching Fellowships provide for significant release from regular duties, and Course Team Symposium Grants offer annual funding for successful applicants to develop a course level blended and flexible learning strategy. This Institute further fosters innovation through evidence-based practice, applied research and scholarship. The university also has an Initiatives Handling Process for major strategic initiatives, and Faculty and School based schemes that deal with larger innovations.

LATISS, however, addresses informal and small-scale innovations, as outlined in this description of Phase One.

Phase One: encouraging and supporting innovation

While some of the institutional issues outlined above may be harder or take longer to address, creating an environment for mutual exploration and discussion of the affordances of new technologies can be immediate and effective. Anecdotal evidence shows that institutional social networks facilitate conversations that previously did not take place, at least in such transparent and inclusive format. Criticism of institutional systems can be aired in open channels, and so can discussion of elearning innovations and pedagogical strategies that are being tried out in different parts of the institution. This is a positive move towards a culture of collaboration, where risk taking is encouraged by the knowledge that others may be exploring similar opportunities. It is also an unprecedented way to take the pulse of the institution on matters related to any topic that may be raised for discussion by participants. While representation of staff in these networks is not uniform, it is growing rapidly in many contexts.

Innovators are in the minority among academic staff at Charles Sturt University, a situation that is typical for Australian universities, and that might be another reason why so little attention and support are provided to innovators. However, champions can have a powerful multiplication effect in their faculties and schools on integrating educational technologies within learning and teaching.

The LATISS was launched on 1 May 2012 by the Information and Communication Enables Learning community of practice, which is facilitated by the Strategic Learning and Teaching Innovation section of the Division of Learning and Teaching Services under the direction the first author. Leading up to the launch, feedback on the concept was sought from key units across the University, in particular, from academics involved in innovation with technology.

LATISS has the following key objectives:

- To communicate to innovators that the University is positive about innovations and innovators
- For champions and early adopters to innovate i.e. support personal innovation so that staff tap into their creative talents to make performance improvements in their own work
- To improve learning and teaching at Charles Sturt University by feeding back the results to appropriate groups and committees
- For innovators to share their innovations with the rest of the ICT-enabled learning community of practice
- To provide support via the Information and Communication Enables Learning community of practice to the innovators - and thus create a "lattice" of support!
- To link up innovation activities.

The public interface to LATISS is a set of Yammer pages that is only accessible to Charles Sturt University staff members. While this limits the extent of sharing to the institutional community rather than opening innovations up to the world, it is an increasingly popular set up in universities and for academics where no commitment to an open access philosophy has been made.

The LATISS concept was formulated by the Strategic Learning and Teaching Innovation section, then discussed by various interested parties, including the Division of Learning and Teaching Services Executive, the Educational Technology Reference Group that represents the four faculties, the Library, Division of Information Technology, Flexible Learning Institute, Education for Practice Institute and the Division of Learning and Teaching Services staff. It was also shared with relevant university committees, so wide consultation has helped to shape its implementation.

The opening page of LATISS links to the following pages: Charles Sturt University innovation landscape; the Division of Learning and Teaching Services support for LATISS; Library support for LATISS; Division of Information Technology support for LATISS.

On the opening page staff are asked to describe their innovation by providing as much as possible of the following seven points:

1. Aim: what learning/teaching aim are you trying to achieve through the innovation?
2. Technology: what technology/technologies will you be using?
3. Objectives: what faculty/school objective(s) are you trying to address?
4. Who: who is involved?
5. When: when do you plan to run this experiment?
6. Support: do you need support? If so, what support do you need?
7. Students: How will the students be supported?

The service was launched with an invitation to a number of academics to put up innovations that they are busy with or planning on the opening Yammer page. Eight academics responded within the first two weeks following the launch. Two further innovations were added soon after the initial eight.

The innovations posted are quite diverse, and some examples are outlined below:

> For a subject with a workplace learning component, the lecturer wants students to be able to add info into cells in a table against workplace capacities and skills that are listed in a column. The idea is for students to be able to add to this over time, as they progress through 3 subjects in a series of workplace learning subjects.

> I am taking the TESOL students from a print-based DE mode of delivery through to a blended mode of delivery and want to demonstrate what blended learning might achieve when they are considering ways to teach their own learners.
>
> We are demonstrating how to create a visual presentation that supports key thinking, and also allows students to learn about creative commons images, copyright, attribution etc. This innovation is a real-world experience, as students are already translating the new practice into their own classroom teaching.
>
> Over the last few years I have experienced a sense of disconnectedness with DE students. The forums are losing their value, as students want an answer NOW, resulting in less communication through this channel and therefore less connection within the cohort. This group of students also lacks the ability to compare assessments in the way internal students do after class and during all night library sessions. I think this communication is important in driving student achievement – most people are after all a little competitive.
>
> I am planning to refine and refocus my "Introduction to Educational Computing" subject. It works very well at the moment, and even though I usually support the idea that if something's not broken it doesn't need fixing, it is a subject that has grown and developed quite organically and needs regular updating as technologies and educational policies change. Newer technologies need to be incorporated - particularly apps and mobile devices. Two of the creative and engaging assessment tasks need to be constrained - students tend to get carried away and make HUGE assignments. Great learning, but difficult to mark and students spend too much study time on them.

The types of support that may be provided by the Information and Communication Enables Learning community of practice through LATISS include advice; brokering support within and external to units such as the Strategic Learning and Teaching Innovation section and doing this within the Division of Learning and Teaching Services; collaboration in activities; linking activities; assistance in software development; providing access to a technical innovation systems environment through the Division of Information Technology; and actual implementation.

The Strategic Learning and Teaching Innovation section has appointed a staff member who does follow-up on the innovation as one of his duties. This staff member reviews the opening page for new innovations, discusses possible support with the Strategic Learning and Teaching Innovation section colleagues, and posts a response to each innovation. The staff member will also follow up with the innovator at the end of the experiment to encourage them to post their findings on the opening page with the original information on their innovation.

It is still very close to the launch and there is currently a long teaching break, so we look forward to seeing more innovations being listed, but at least some innovators have shared their work and it is now known that Charles Sturt University is proactive in supporting its learning and teaching with technology innovators.

Phase Two: analysing the innovation for niche/wider applicability

Phase two of the process is where innovations that have passed an initial proof of concept phase can be assessed for feasibility, and potential for application beyond the original development context. This presents challenges around the sharing of information at an individual level, and knowledge management by the institution, so that even if a development will proceed no further, the experience gained through exploratory phase is not lost. The ability to pursue this form of evidence based practice is important to produce efficiencies, and to guide teaching and learning development at both individual and strategic levels. This has been problematic in the past, however, as innovators tended to stay off the radar so the 'suspect' nature of their activities did not attract attention. A more transparent process and enacted support for innovators will hopefully help to address the challenge.

From an institutional perspective, it is necessary to determine if the innovation addresses wider needs: either for a particular niche or for use across the University. Either case would be fine, but there is currently no specific process in place in most institutions to either gauge or encourage wider interest, or to determine what level of investment might be justified given the prospects. Central service units often showcase and highlight support available for innovations. However, it is not uncommon to find an original developer trying to take responsibility for all user support and professional development in order to disseminate their work. Different sets of skills are involved in development, dissemination and support; so different people should be allocated to these processes, including professional development, customization of learning designs, end user support and technical maintenance.

A challenging question in this context is, what kinds of evidence need to be gathered and presented to convince other faculty and institutional leaders that support or further investment in justified? Few innovators in learning and teaching with technology would aim to present a business case to the institution to secure the future of their creations. It is more likely that they would evaluate its impact on student learning in different educational contexts and publish the results in conference proceedings and scholarly journals. These two forms of reporting are equally valid, but serve very different purposes, so the question needs to be addressed from the perspective of the different interests and priorities of those involved.

A further challenge relates to the emergent nature of learning innovations, and the fact that it may be impossible to predict or fully appreciate potential in the early dissemination stage. The only reliable prediction about the use of new technology in education is that forecasts are usually wrong. It is often not possible to predict how people will use a new system or tool until they actually get involved and try it. The eventual uses often come as a surprise to the developers. It is therefore asking the institution to take a risk in backing emergent innovations, the prospects of which cannot easily be framed in ‘business language’. As Lorraine Stefani (ACODE 58 Presentation) said ‘we must be more business like, but not more like business’ as the impact of promising innovations cannot be costed, yet investment decisions demand an evidence-base of a ‘business like’ nature. Broad consultation is also required to determine processes and structures for Phase 2 of the Innovation support initiative. However, this remains a work in progress for most institutions.

Phase Three: University support for innovation

Once an innovation has been reviewed and scope for wider application identified, the following issues need to be addressed:

- Identify affordances and strategies to promote integration into pedagogical practice
- Licensing arrangements (if appropriate)
- Professional development requirements and strategies
- Change management plans
- Implications for guidelines/policies;
- Staff and student support requirements
- Ongoing financial commitment

These are all significant issues in the university context, which given the pace of change, will take some time to work through and involve a degree of uncertainty around eventual outcomes. Again, broad consultation is required, and possibly also the establishment of new working relationships. For example, some of the innovations examined by Gunn & Herrick (2012) involved collaboration across teaching departments, libraries, central teaching and learning and IT support centres. Establishment of these cross-functional relationships for a particular project was usually not an easy task, so it may be reasonable to expect that doing so on a longer-term basis would be equally challenging, at least in the establishment phase. Shifting the culture and practice of learning and teaching within an institution is no simple task either. A suitable approach is identified in the ‘ecologies of learning’ concept defined in a report from the UK Association of Learning Technology (ALT 2010). The multi-faceted support strategies provided through flexible and responsive systems that are required to articulate such ecologies present multiple challenges to established institutional culture and practice.

Phase Four: Sustain the innovation

As well as supporting early stage exploration and broad collaboration, institutional social networks provide a way to gauge popular interest in particular innovations, which in turn can be used to guide decisions about what to support and where to invest resources. Gunn & Herrick (2012) recommended ways to support innovations after an educational concept has been proved either with or without the start up funding that most institutions already provide. Proposed actions include the use of initial scoping information gathered through systematic process as an input to design and decision-making; and use of more formal project management techniques by multi-skilled teams for the development and dissemination phases. Two critical success factors, however, are choosing the right innovation to back, and getting the right team together to promote it. The common situations where innovators and initial developers are also expected to take responsibility for dissemination and provide all forms of support have proved to be unrealistic. This is not surprising given the wide range of skills and the time commitment involved in these different activities. Evidence from their investigation of 22 case studies (Gunn & Herrick 2012) showed that the number of years in development and levels of investment were not reliable predictors of dissemination or sustainability prospects. Since management backing does not appear to be the most reliable predictor of popular interest, it may be posited that a more democratic method for choosing what to support could lead to better results.

It is critical to employ appropriate change management strategies to sustain innovations in learning and teaching with technology. Managing change for enterprise-wide impact in higher education is particularly problematic since people are central to the process, and it is therefore necessary, as Fullan (1991, p350) suggests, "…that we explicitly think and worry about the change process" in educational reform. The LASO (Leadership, Academic & Student Ownership and Readiness) Model for Technological Transformation in Tertiary Education attempts to address the wider context in which the infusion of educational technologies takes place, and acknowledges that the process of enterprise-wide technological transformation is complex with many dislocations, dilemmas and uncertainties (Uys, 2007). The LASO model proposes that top-down, bottom up and middle out strategies operate in unison to achieve sustainable change (Uys, 2010; 2009a,b &c).

Summary

A service like LATISS is designed to fill a very specific void in the typical innovation landscape at universities. It is very early in the use of LATISS, but it is promising that 10 innovations were listed in the first few weeks after the launch of this service. Although it limits the spread of innovation to staff in a single institution through a social networking extension to the intranet, this is a sufficiently major change for many, and will inevitably lead to wider sharing as individuals engage in various external networks. It also provides an important preliminary step into the social networking world for novices.

A local version of the LATISS and the four phase learning and teaching with technology innovation management model could be of value to higher and tertiary education providers who wish to ensure successful innovation. A service like LATISS could play a significant support role in Phase One, and the strategies for action recommended by Gunn & Herrick (2012) could usefully address later stages of the process. An ecological approach is essential to the innovation process, which has neither a fixed start nor end point, and where the outcomes of dissemination strategies often cannot be predicted before they materialize. The unpredictable nature of innovation presents many challenges to planning and budget cycles and the forecast based futures of higher educational institutions. However, failure to respond to these challenges with flexible and supportive strategies for innovation creates the unacceptable risk of failing to move with the times in an environment where no university can afford to be left behind.

Faculty experiencing first-line implementation of Technology Enhanced Learning

Marichelle van Deventer
North-West University

Higher education is entering an interesting period of change. Faculty and students will have to adapt to a more technologically enhanced environment for teaching and learning. Adopting new pedagogy can place a critical responsibility on faculty. This article evaluates members of a small faculty's experience of the implementation of laptops as part of Technology Enhanced Learning (TEL) at a residential higher education institute (HEI) in South Africa. The study population comprised 36 first year Humanities students, the Faculty Dean, and seven lecturers of the first year modules. Data collected through semi-structured interviews, focus group discussions and an open ended questionnaire were captured in an integrated dataset using Atlas.ti^{TM}. Coding and categorization focused on the requirements of TEL in the faculty and the researcher derived at two themes: (i) Demands of TEL and (ii) initiation characteristics.

Keywords: Faculty; Technology Enhanced Learning; Information and Communication Technology

Introduction

With traditional pedagogical methods in higher education (HE), changing at an accelerating speed to online or blended learning, change is expected (Tang & Austin, 2009). Adopting the use of new (and some not so new) Information and Communication Technology (ICT) devices, e.g. laptop computers, iPads, smartphones, tablets, and android devices as learning technologies have implications for HE teaching pedagogies. This implies change beyond verbal and visual learning to a virtual way of teaching and learning. Traditional learning principles should be revisited and adapted accordingly (Njenga & Fourie, 2010; Proserpio & Gioia, 2007) to develop teaching and learning strategies to incorporate the strengths and opportunities of online learning with those of traditional modes of learning (Emerson & MacKay, 2010). Moving towards a more technologically enhanced learning approach seems revolutionary yet necessary.

Technology enhanced learning

Technology enhanced learning (TEL) is "characterized as maximizing the best advantages of face-to-face learning and multiple technologies to deliver learning" (So & Brush, 2008, p. 321). Salinas (2008) suggests that this new environment relates to enhanced motivation, new roles for students and faculty, and improved learning outcomes. For a transition like this to take place, a paradigm shift is predictable. Teaching and learning have to move away from a teacher-centered approach to a cooperative and student-centered model (Salinas, 2008; Weaver & Nilson, 2005).

Adapting to this environment poses new responsibilities for the faculty. Faculty have to become creative in the redesigning of their courses in order to actively integrate technology for learning (Emerson & MacKay, 2010; Proserpio & Gioia, 2007; Tang & Austin, 2009; Wurst, Smarkola, & Gaffney, 2008) and create innovative learning opportunities for their students (Proserpio & Gioia, 2007). Technology integration in HE demands major changes in the way faculty views technology, as well as in teaching and learning (Salinas, 2008). Faculty has to combine technology, assignments and learning material in such a matter that it leads to optimal learning. This may ultimately lead to better student learning and satisfaction, and the best combination may enhance faculty members teaching abilities and lead to better teaching evaluation (Tang & Austin, 2009). Faculty are compelled to consider students' "learning styles, perceptual modality preferences and computer or Internet proficiency when introducing technology into their teaching" (Tang & Austin, 2009, p. 1252). These changes lead to additional challenges for teaching and learning (Tang & Austin, 2009) as the roles of students and faculty during course communication change (Proserpio & Gioia, 2007; Salinas, 2008; Wurst, et al., 2008). These changes result in instructional implementation of the technology; it is not technology itself that effects the learning that takes place (Tang & Austin, 2009).

The Internet with its quick access to a wealth of information does not necessarily lead to meaningful knowledge creation and demands much more from faculty to ensure the transformation of information into knowledge (Guri-Rosenblit, 2005). The availability of modern technologies does not imply educational usage thereof

(Proserpio & Gioia, 2007). This statement highlights the importance of the compatibility of ICT with the users, their preferences, and the way technology is implemented.

Faculty members often remain sceptical about the value of these new technologies to improve teaching and learning and research on the topic is still inclusive (Salinas, 2008). Sufficient knowledge and skills are needed to ensure that the use of technology is beneficial in teaching and learning (Kay, 2008). Research should focus on developing a better understanding of ICTs used at HEIs and the effect thereof on the different role-players. Therefore, this paper aims to contribute towards the understanding of a HE faculty experiencing first-line implementation of Technology Enhanced Learning to foster sustained research, support, and training for high quality teaching and learning.

Research design and methodology

Context of the study

The Teaching and Learning Committee of the North-West University (NWU) launched a pilot study to determine the feasibility of issuing laptops to all students on the Potchefstroom Campus. They targeted the smallest faculty on the Potchefstroom Campus and at the onset of the 2011 academic year each first year student received a custom loaded laptop computer. The cast contained *inter alia* anti-virus software, MS Office™, OneNote™, and several e-books. The computers linked to the NWU wireless Internet network that gave the students access to e-Fundi—the university's learning management system (LMS) which provided links to an email account, the library's resource database, electronic study guides, communication to faculty, discussion forums, technical assistance, posting of assignments, and online assessment. In spite of contradictory indications from the literature, the Committee aimed to determine if the Virtual Generation students perceived their teaching and learning experience to be positive (Fried, 2008; Kirkwood & Price, 2005; Mottarella, Fritzshe, & Parrish, 2004; Njenga & Fourie, 2010; Tang & Austin, 2009; Wurst, et al., 2008). The Committee also aspired for improved student achievement as a positive spin-off of the "Laptop Project."

The Dean of the involved Faculty's strategic plan aligned with the HEI's change towards technologically driven teaching and learning and its perceived competitive advantages for the global market (Rice & Aydin, 1991). The Dean's vision was to gradually evolve ICT into teaching and learning, shifting the current instructivist teaching paradigm towards a learner-centred approach (Salinas, 2008), changing the perceptions of faculty members and students about dealing with information and content. This change encompassed establishing new partnerships between teaching and learning responsibilities at his Faculty.

Participants

The participants comprised the total intake of 36 first year on-campus students, registered for a qualification in the Humanities, seven Theology faculty members responsible for the first year modules and the Dean of the Faculty of Theology.

Methods

The study followed a qualitative case study design to capture insight, discovery, holistic descriptions, and a better understanding of the experiences of lecturers during TEL (Leech & Onwuegbuzie, 2007; S. B. Merriam, 1998; 2009). The researchers collected data at several occasions over a period of one year, according to five strategies:

(i) An interview with the dean of the faculty which focussed on his strategic views on the establishing and implementation of a TEL environment.
(ii) Semi-structured individual interviews with six purposively selected students. The questions focused on students' expectations, their experiences and their use of the technology for academic or other purposes.
(iii) A semi-structured focus group discussion with faculty members focussing on the integration of technology into teaching and learning.
(iv) A semi-structured focus group discussion with seven first-year students that focussed on how technology supported their learning.
(v) An open-ended questionnaire posted to the learning-management system for all 36 participants, although only fourteen students responded to the questionnaire.

The use of the different strategies aimed to triangulate the data of the semi-structured focus group discussions with faculty's experiences that added value to the results.

Data analysis

Data were analysed with the focus on the requirements of TEL on the faculty. Atlas.ti™, a qualitative data analysis and research software programme, combined the textual data from the five data collection strategies as an integrated dataset. The author coded and categorized the participants' responses into 68 codes, seven categories, and two themes according to the use of the constant comparative analysis method (Leech & Onwuegbuzie, 2007, 2008). This method identified underlying themes from the data. The researcher grouped phrases together as meaningful parts and linked them with a code. Subsequent chunks of text were pared with existing codes. Codes were grouped together due to their similarity as categories, and then as themes (Figure 1).

Findings and Discussion

The findings are presented according to the two themes identified from the data: (i) Demands of TEL and (ii) initiation characteristics (Figure 1).

Demands of TEL

The theme demands of TEL originated from four categories: (i) Mind shift for teaching and learning with technology, (ii) concern about students, (iii) barriers caused by the laptops, and (iv) added responsibility.

Mind shift for teaching and learning with technology
Some faculty members had little confidence in the changes stowed upon them regarding their new roles and pedagogical practices of integrating technology into their established learning environments. Although there was conscientiousness amongst faculty members about their new role and responsibilities (seeGuri-Rosenblit, 2005), the new technologies required that faculty had to make a mind shift and develop new teaching and technology skills. Nevertheless, faculty still felt responsible to attain the previously defined pedagogical outcomes that did not take into account a different teaching environment (Mottarella, et al., 2004). They took the responsibility to adhere to and reach these outcomes during a contact session seriously, in spite of a dramatically changed learning environment. This stance compromises the ideals of TEL and illustrates resistance to change:

> I did not make any mind shift. My preparations remained the same. I teach or lecture the same way while I will communicate with them through e-Fundi and all that...

Due to their insufficient knowledge on TEL, faculty members reduced ICT's potential to the use of e-Fundi, a dependable Sakai™-based e-learning platform (Abbad, Morris, & de Nahlik, 2009; Fichter, 2005); some computer applications; and PowerPoint™ presentations. These previously used ways of teaching let faculty to believe that traditional learning can continue as usual and that the students needed to adapt:

> I did not need to make a paradigm shift but my concern is not about myself but about the students (Faculty, focus group discussion).

Faculty members were no longer considered as the *sage on the stage* (Palloff & Pratt, 2003), with students perched at their feet, ready to absorb any knowledge. Faculty should evolve to *guides on the side* (Palloff & Pratt, 2003) who holistically share in the teaching learning experiences of their students. This will involve role adjustment and a pedagogical shift to learner-centred learning. However, not all of faculty shared this progression and they strongly voiced their traditionalist defiance:

> I must reach my outcomes...There are outcomes to be achieved and someone says make it work and I say it's not working and we are wasting time by this argument its working, make it work, it's not working, make it work and so forth and where is the process of teaching and learning it's being hurt (Faculty, focus group discussion).

Faculty members agreed that the success of the pilot project depended on their positive attitude and change of teaching philosophy according to the demands of TEL. Change did not happen easily. Resistance, being one of the most important stumbling blocks in implementing e-learning (Njenga & Fourie, 2010), was strongly experienced by some faculty members:

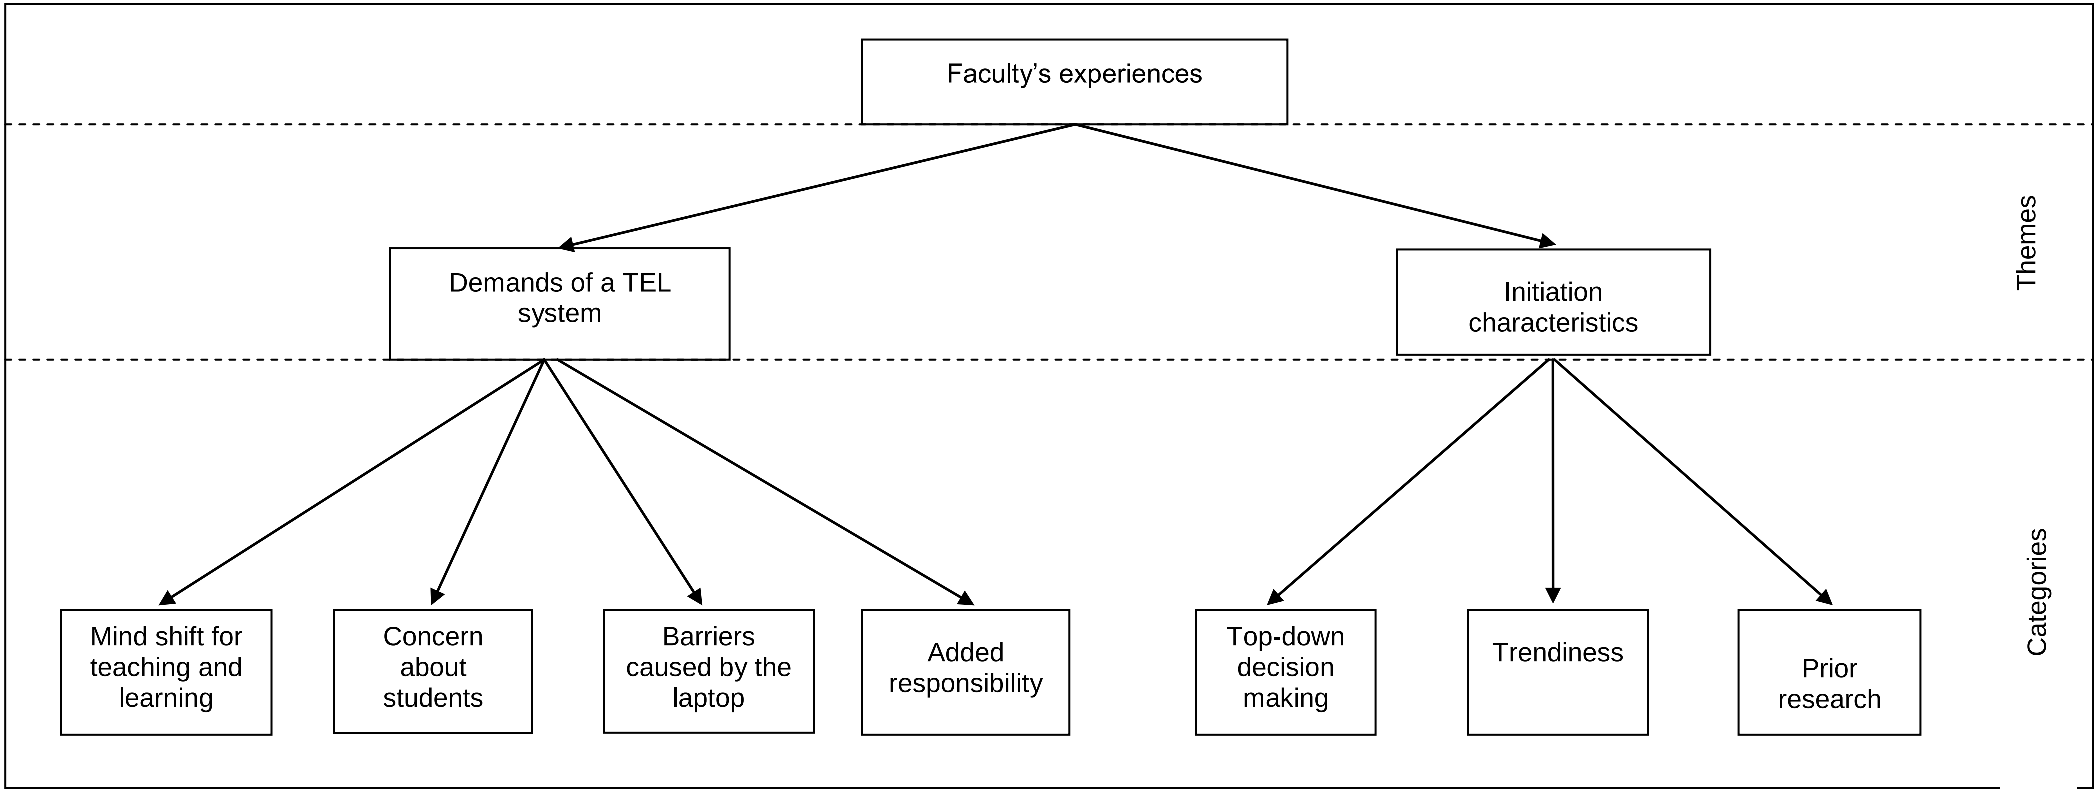

Figure 1: Categories and their distinguished themes relating to the Faculty's experience of the implementation of Technology Enhanced Learning at a residential Higher Education Institution

> I think when we closed last year I was halfway with my preparation for Greek for this semester and then only to come back in January and hear that there is this thing. Can you imagine now I'm halfway with my work. Some of my tests are already set. I know I am going to do this work at this time and so forth. You had your schedules and know you have to adapt to the new system. It's a traumatic situation that we've started this academic year (Faculty, focus group discussion).

Concern about students

Management initiated the laptop initiative, but during the first year of the rollout, faculty did not fully buy into the change. They were uncertain about the advantages of the endeavour for the students, and felt that more research should have been done. Guri-Rosenblit (2005) warns against these substantive issues of ICT implementation in HE. Faculty members were concerned how the shift towards TEL would affect the students. Faculty members not from the Virtual Generation voiced their concerns that the pilot project was too much, and too fast. They maintained that the approach did not take into account the technology preferences of the Virtual Generation. The students voiced their concerns:

> I was affected in a huge way, when I was used to taking note on paper and now it is done on the laptops it's a big change which on the other hand it slows you down, because I'm still getting used to the typing (Student, open-ended questionnaire).

> The change, previously just listening to the professor and taking notes (it's easier this way) now it's different. Somehow it can be in the negative, it can even effect your concentration or the effectiveness to think... This can influence your learning experience. At first you don't feel all together in class with all these things in the class. I felt like, am I really going to manage this (Student, individual interview).

Uncertainty about the advantages associated with TEL and the unforeseen mistakes and gaps that accompany such change predominated faculty members' concern for their students' learning process:

> Has it been resolved by whoever that the future is an e-learning environment as they describe it, and why, and what are the advantages and why is it better than the previous? (Faculty, focus group discussion).

> I'm very worried about is actually the gap which is created especially in the contact session. The focus and participation is actually reduced. The attention is now given to the computer (Faculty, focus group discussion).

Barriers caused by the laptop

In their minds, incorporating ICTs in-class proved to be more of a hindrance and faculty preferred the traditional teaching environment. Obtaining and maintaining students' attention while they were interacting with their laptops irritated the lecturers and disrupted their classes. Faculty asserted that the laptops distracted students' attention in classes and that students required maturity and discipline to focus their attention on the facilitation at hand:

> I think what needs to be done is a way of… if using a computer in a contact session, to prepare the students, they need that preparation. Yes, they need that shift for them to be able to use the computer and concentrate at the same time (Faculty, focus group discussion).

The in-class use of the laptops diminished the interactivity with course content during contact sessions and estranged social interaction in real time and space:

> I feel that a contact session, in the deepest sense of the word, it must be a face to face talk and then questioning and answering, discussing, rather than a communication by passing through the computer... (Faculty, focus group discussion).

However, they acknowledged that out of class use of the laptops was convenient. Communication and studying could now take place in the students' own time and space; and that this boundless environment had a positive effect on TEL (Guri-Rosenblit, 2005; Mottarella, et al., 2004; Proserpio & Gioia, 2007; Tang & Austin, 2009).

Besides the insufficient attention and focus in-class, faculty were concerned about possible loss of traditional skills by students in the TEL environment:

> The other problem I said to the class is that yes you can use this tool but the problem is when you go to the exam I'm not going to allow you to use the computer. I need to be able to write the Hebrew characters with your own hand so in a way computer is not helping in this situation (Faculty, focus group discussion).

In spite of the challenges, some students, faculty and management believed that TEL could contribute towards an improved teaching and learning experience:

> Improvement of teaching and learning is like that, it can lie within effective access to information that one has as result of this teaching aid (Management, individual interview).

> The level of teaching that can be supported by technology is much better if everybody involved adapts to it and takes part (Student, open-ended questionnaire).

Faculty made an effort to incorporate the laptops in class and use other available technology; everything to the students benefit:

> They make quite an effort to get us involved with the laptops (Student, individual interview).

> A few of the older lecturers or Prof. seem to have problems with the e-Fundi. They say they don't quite know what to do yet. And one of the other lecturers uses e-Fundi but loads the material wrong. He puts the dates wrong, but he is working on it, so he is managing. They are all definitely making an effort to learn (Student, individual interview).

> They undoubtedly do everything to be to my advantage. I will not be disadvantaged because of e-Fundi or the computers (Student, individual interview).

Added responsibility
Faculty feared for the quality of their teaching. Previously insurmountable information at students' fingertips could enrich their learning experiences, yet did not replace the distinction between information and knowledge (Guri-Rosenblit, 2005). The responsibility fell on faculty to devise learning strategies to ensure that students benefited from instant access to data (Wurst, et al., 2008). Faculty members pronounced that it was not their responsibility to teach computer literacy to students and viewed TEL as an additional burden that will delay students' academic development:

> The students needed the proper preparation to use this tool, because I think instead of helping, it's not… it can't progress to their full potential at the moment it's not going to work well especially with the languages (Faculty, focus group discussion).

Initiation characteristics

Three categories relate to the theme initiation characteristics: Top-down decision making, trendiness and prior research.

Top-down decision making
Changing a pedagogical system requires careful planning and inter-systemic collaboration. Several factors should be taken into consideration like, potential users, the effects on these users, management and existing research. Faculty had to make a systemic change. Adapting to TEL meant working through much uncertainty, concern and reluctance. In this kind of development all role-players should be involved (Davis, Bagozzi, & Warshaw, 1989). Adoption of TEL takes effort and careful consideration. A partnership between all role-players is vital before changing from traditional classroom-based teaching and learning to TEL. This may be the most important aspect in successfully integrating TEL at traditional HEIs. The Dean of the faculty conceded irrevocable changes in HE, but faculty members experienced being excluded from this process:

> We don't know why it has been implemented, we were simply confronted with it and it happened like that (Faculty, focus group discussion).

> We were not part of the process; we were just informed that from now on it will be like this (Faculty, focus group discussion).

Faculty members felt that although change was mandatory, their opinions were not heard and that the responsibility of reaching traditional teaching and learning outcomes was still their responsibility:

> What I'm trying to say here is having introduced to the whole system and it's like we (personnel) are not listening to each other. When I stand up and say in Greek it won't work in our environment someone will stand up and say make it work and you see now there is a struggle I must make something to work while time is passing by (Faculty, focus group discussion).

> I must reach my outcomes, there are outcomes to be achieved and someone says make it work and I say it's not working and we are wasting time by this argument its working, make it work, it's not working, make it work and so forth and where is the process of teaching and learning it's being hurt (Faculty, focus group discussion).

Besides being pushed far beyond their comfort zone, faculty members remained true to their perceived responsibility towards their students:

> I will do anything to improve things for my students. Really, I think it is every lecturer's responsibility (Faculty, focus group discussion).

Trendiness

Faculty members experienced this change to be beyond feasible, especially for languages. Being pioneers in the use of TEL did not only place much pressure on them, but they felt concerned about possible errors during decision making:

> We pay a price for being trendy and being first and other people might learn from our mistakes, but we learn from our own mistakes and worst of all the students learn from our mistakes and I don't know if it can be corrected (Faculty, focus group discussion).

> I don't know if they (lecturers) had any...A course or something to teach them how to use the technology better. It seems to me that some of them (lecturers) are forced to use it. So they are doing it to meet the minimum requirements, but it is of little use, giving us computers to enhance the learning experience without equipping them with the abilities to meet the possibilities that has been created (Student, individual interview).

Prior research

The success of the pilot project depended on the initial project preparation, which included thorough research of the system requirements to adopt TEL. Thorough research is vital when changing a pedagogical paradigm. Insufficient knowledge of this system aroused questions, like "Was significant research done before the initiation of the change?"; "What was the rationale for the project?" and "Do we know enough about the generation students we teach?":

> Much more research should have been done beforehand on all possible aspects, advantages and disadvantages, and experience from other people should have been interpreted (Faculty, focus group discussion).

> I feel that it is my responsibility as a faculty member if it is a new system at the university let it be well researched let us be well trained as faculty and professors and let the student be well oriented to the system (Faculty, focus group discussion).

> I think we fooled ourselves. We said children were computer literate from the age of four years and that is why it will be wonderful for them to continue with the computer here. We were wrong, it isn't like that (Faculty, focus group discussion).

Faculty had to plan ahead, consider controlling measures, as well as augment stereotypical classroom teaching. Both ease of use and usefulness depend on how faculty design the classroom experience and not on the technology itself (Proserpio & Gioia, 2007). Having faculty members trained to effectively integrate ICTs with their teaching will be a vital factor to promote learning (Fried, 2008; Proserpio & Gioia, 2007; Wurst, et al., 2008).

Conclusion

All motives, rewards and promises of TEL have not yet been explored. However if technology is incorporated to suit both the user and the pedagogy the result can be surprising. The researcher is suggesting the following technology implementation aspects that might be helpful during this adaptation (suggestions is applicable for this context):

1. Top-down decision making creates resistance and negative attitudes in faculty. Faculty members need to be involved from the initiation phase of TEL to become a motivated and transformed teaching corps.
2. A partnership between all system role-players must be formed.
3. There is a need for sustained overt communication between management and faculty members.
4. Current research in the field needs to be studied and the value of TEL needs to be communicated to faculty members.
5. For a TEL system to function sufficiently all learning material and the method of teaching will have to change.
6. To move away from the traditional teaching culture faculty members can start exploring a more constructive, learner-centred approach to teaching.
7. Training members of faculty for their new role and the pedagogical transformation is very important. Training can focus on new innovative and creative ways to effectively integrate technology with teaching and learning and the appropriate learning strategies effective in TEL.

To improve student learning and success in a science field while at university, it is important that students begin their studies with good basic science knowledge. Thus, it is important for high school science teachers to be teaching current scientific methods. To update their skills high school teachers need to participate in professional development programs to update their own knowledge of current science research and techniques used in labs. Towards this goal, the John A. Burns School of Medicine at the University of Hawaii developed a professional development program for high school science teachers. In 2012, eight high school science teachers attended the program for eight week days over a two week period. This study is a report of the teachers' experiences within the program. Specifically, this paper reports on the results of the teachers' evaluation of the online materials and their perspectives of real world application of the learned material are investigated. The data set in this study includes all eight teachers' pre-survey responses and final survey data.

Keywords: professional development, online learning, blended learning, educational technology.

Introduction

High school teachers are persistently looking for ways in which to inspire youths to commit to the science field. The competitive nature of the science field encourages a thorough understanding of current scientific techniques and knowledge to become successful in science. It is essential for teachers to be up to date with current skills and knowledge of science to effectively educate students. As The Committee on Science Engineering and Public Policy suggest (2007), professional teacher development is necessary to evolve and boost the current state of science education. Studies investigating the effects of professional development on science teachers have been positive. For example, Radford (1998) reports that teacher development training improved teachers' confidence to teach and content knowledge within science. Moreover, teachers who engage in hands-on science benefit in their teaching practices as there is a clear indication of improvement in creating a culture of science within their classrooms (Cuevas, Lee, Hart, & Deaktor, 2005).

Unfortunately, it is evident from previous research that it is scarce for high school science teachers' to attend professional development programs frequently and engage in hands-on lab work (Parisky & Boulay, 2010; Boulay, Parisky & Campbell, 2010). In efforts to help facilitate student learning and keeping teachers up to date with current research, online materials are fast becoming a popular method to augment offline learning (Parisky & Boulay, 2010). This type of learning is termed blended learning and is an important tool in the current professional development program. Past studies have found great success in implementing online learning materials. For example, one study found that introducing a simulation program prior to engagement in labs increased comprehension of techniques and concepts in comparison to those who did not have access to the simulations (Martinez-Jimenez, Pontes-Pedrajas, Polo, & Climent-Bellido, 2003). Utilizing a blended learning approach, The John A. Burns School of Medicine (JABSOM) developed a professional development program for high school science teachers with additional online materials to augment face-to-face learning.

To evaluate the usefulness of the program and the online materials, this study seeks to investigate how eight teachers' evaluated the online materials after engaging in a professional development program. Additionally, teachers' comments on how the learned material in the program relates to real world situations are examined.

Method

Program Development

Preparation for the professional development began in 2009 with the formation of the online materials (see Boulay, Anderson, Parisky, & Campbell, 2009). The first time the professional development program initiative was conducted occurred in 2010 at JABSOM (see Boulay, Parisky, & Fulford, 2010). The program was run three years in a row, each time taking place over the summer period. Each year, the program undergoes an evaluative procedure by which the head researchers and leaders consolidate the effectiveness of the program and make any changes necessary to update the program for the benefit of the participants. Additionally, online materials were developed to augment the learning of the high school science teacher's participation in the program (see Boulay, Anderson, & Parisky, 2009; Boulay, Parisky, & Campbell, 2010).

Data Sources

The data sources for this study include all of the teachers' pre-survey responses and all of the teachers' final survey responses. The pre-survey gathered additional information about the teachers' experience and background in education. The final survey included five major sections asking about the teachers' personal molecular biology definition, their experiences in the program itself, the molecular biology techniques they learned, their evaluations of the scientists' presentations, and their evaluation of the website. Teachers also completed final written reflective statements. The final written reflective statements included prompts on their experiences in five general areas. These areas asked teachers about their initial goals before entering the program, knowledge/skills acquired during the program, how participating in the program impacted their teaching, how participating in the program influenced their attitude towards teaching, and how the program impacted on their goals.

Participants

Eight high school science teachers were invited to participate in the 2012 professional development program. Teachers ranged in total teaching experience from 2-15 years (M = 8.5, SD = 4.14). Teachers taught at their current school for an average of 6.75years (SD = 2.49). The teachers' latest academic degrees varied. For example, the latest academic degrees awarded to the teachers were MEd in Secondary Education, M.S. in Biological Oceanography, B.S. in Biology, and Post-Bachelors in Science. The year the last degree awarded to the teachers ranged from 1994 to 2010. Teachers were selected for their multiple assumed roles in their high schools. For example, some of the extra roles teachers assumed were Assistant to the Director of Curriculum, Department Chair, Science Olympiad Coach, Advisor, Instructional Leadership Team Leader, and Science Fair Assistant Coordinator. Of the 16 techniques teachers reported to have used before, the most common techniques were pipetting, centrifugation, DNA electrophoresis, and microscopy. In the professional development program various techniques were practiced in the lab including multiple techniques new to teachers. Some of the main techniques practiced in the program were centrifugation, DNA electrophoresis, DNA plasmid purification, DNA ligation, restriction enzyme digestion, western blotting, polymerase chain reaction, use of a spectrometer, immunostaining, cell culture, tissue sectioning, microscopy, and pipetting.

Analysis

Investigator triangulation (Keyton, 2006) was used in thematic analysis of the current data (Braun & Clarke, 2006; Glaser & Strauss, 1967). In the original data from 2010, multiple researchers agreed upon a set of 24 codes without any *a priori* hypotheses or themes. In 2011, researchers coded with the original set of codes in mind but several extra codes arose. In the 2012 dataset, 27 agreed upon codes were used to manually code post-surveys and final written reflective statements. In this study, only the codes labeled *website* (W) and *real world application* (RW) are investigated. In the thematic analysis nature, codes were designated as important if they were recurring (same thread of meaning), repeated (repetition of key words or phrases), and forceful (stressed phrases or words) (Owen, 1984).

Results

The results are separated into three sections. Firstly, teacher's responses to one core question in the pre-survey are reviewed. Secondly, teachers' website experiences and evaluations are reviewed. Thirdly, teachers' perspective of real world application of the content learned in the program is reviewed.

Pre-survey

Program expectations
The last question in the pre-survey asked teachers what their expectations were for the professional development program prior to participating. The most frequent theme in this question was teachers' goal of improving their abilities to help educate their students. For example, some of the teacher responses to the question were:

> To gain knowledge and experience to take back into the classroom. Also, to stir up more of an excitement first within myself, then transfer it unto the students.
>
> Learn, Learn, Learn... Advance my lab skills to be able to teach my students.
>
> Learn real-world applications of biological science principles to share with my students and to promote some career choices.
>
> I would expect to have a much deeper understanding of molecular biology concepts, learn new techniques and increase my skill level to make me a more effective instructor for students and teachers.

Undoubtedly, teachers show a concern for the welfare and future of their students. As noted above, teachers aim to inspire students into the science field, once they complete high school, and to help them succeed in their future. The following excerpts from teachers after participating in the program shows that their expectations for the program succeeded.

Website

Any reference made to the online materials was coded as *website* (W). The online materials received very positive reviews from the teachers. A theme within the W code is the teachers' perspective of using the website in their own classrooms. For example:

Classroom application using online materials

> … I will use it more as I improve my current curriculum of my molecular biology course at my school.
>
> The content on tissue culture (the video) was useful and I will use this in my class with plant tissue culture.
>
> This is a great resource for teachers to use in the classroom.
>
> I plan on using it (the website) more in the future as I expand the curriculum in my courses.
>
> I will definitely be sharing this (Information of Safety and Laboratory Equipment and Protocols) with my students.
>
> I plan to use the website materials (particularly Module 1) to help my students learn more about the laboratory procedures and techniques that I hope to cover in class.
>
> I will use the website material for before I start the lab activity with my students. I will use it as homework for them.

Real-world application

Any reference made to the application of current research was coded as *real-world application* (RW). Especially from the evaluations of watching professional scientist presentations, teachers' commented on the importance of real-world examples to take back to their students. For example:

Classroom application of real world research

> I loved learning about what the researchers are currently doing. I will be using examples from their lectures in my classes. I now have many more answers to the dreaded question "why do we need to know/learn this?" Just being able to give specific examples of how the lab techniques are used today to find new breakthroughs will be extremely valuable to me and my students.
>
> I would also love to have any of the scientists come to my class to present what they do to my students. Nothing beats real-life experience and they can provide more for my students when it comes to true application in research.
>
> Just learning about what is going on right here in Hawaii. I would never have known about the great things happening right now if I did not get to hear their presentations. I would love to have them speak to my students and get the younger generations excited about science and research that they can do here at home.
>
> By looking at the facility and learning from the people who actually works in it, I could definitely give "real-life" example of why we're learning molecular biology, as it is often the questions of students.

Conclusion

In conclusion, the results of the present study describe the usefulness of the professional development program and the online materials. The eight high school science teachers reported positive experiences after participating in the program. Before participating in the program, it was clear that teachers wanted to learn new material or update their skills to help their teaching abilities. After participating in the program, teachers found the online materials to be very helpful to them but also to their students and future curriculums. Incorporating online materials into an educational setting is also being introduced and tested at the tertiary level. For example, Andrewartha and Wilmot (2001) describe how students learning style is altered when utilizing computer based program to replace existing face-to-face teaching. By integrating virtual learning during high school, students transitioning college may benefit immensely. The evaluation of the online materials in this program clearly indicates the usefulness and attainable application of extending online learning into college curricula.

Meeting the scientists in particular gave teachers some real world examples to bring back into their classrooms to help show students why a career in science is important. Making clear the usefulness of scientific research to high school students, it is more likely their dedication to the field will extend into college. Keeping this in mind, future professional development programs should seek to update both teachers' knowledge and abilities in a scientific lab and teaching skills to bring back into their classrooms to benefit students success at the tertiary level.

A blended approach to Canadian First Nations education: The Sunchild e-learning community

Norman D. Vaughan
Mount Royal University

The purpose of this research study was to investigate if and how a blended approach to Canadian First Nations education could be used to foster student engagement and success. The study examined the Sunchild E-Learning Community program through the lens of the *Seven Principles of Effective Teaching* (Chickering & Gamson, 1999). Data was collected via an online survey, interviews, and site visits. The study participants indicated that the deliberate and intentional integration of mentors at local learning centers with online teachers, who provide synchronous tutorials through the use of a web-based learning management system and conferencing tool, was the key to academic success.

Keywords: blended learning, First Nations education

Introduction

The Sunchild First Nation Reserve (40) is located in the western central part of Alberta, Canada. The reserve has an area of 52.18 square km. As of 2008, the First Nation had a registered population of 1209 people, of whom 732 live on their reserve (Government of Canada, 2008).

In 1999, members of the Sunchild First Nation considered the lack of education in their community and decided alternative methods were needed to reach First Nations students. They discovered that:

- First Nations students faced unique challenges including family and legal situations, time away from class and relocating to new homes.
- Many First Nations students were adults. These students wanted to upgrade and build a better future while meeting their current schedules and responsibilities (Sunchild E-Learning Community, 2012).

In order to address these challenges the Sunchild E-Learning Community Program was established. This program adopted a blended learning approach for high school courses by combining the use of mentors at local learning centers with online teachers who provide synchronous tutorials through the use of a web-based learning management system and conferencing tool.

The purpose of this research study was to investigate if and how this blended approach to Canadian First Nations education could be used to foster student engagement and success. All students enrolled in the Sunchild E-Learning Community were invited to complete an anonymous online survey in the fall 2011 semester. Online follow-up interviews were conducted with students in the winter 2012 semester as well as online interviews with learning centre mentors, online teachers, and administrators involved in the program. In addition, site visits to learning centers were undertaken. The following three questions were used to guide this study:

1. What are the advantages of a blended approach to Canadian First Nations education?
2. What are the challenges?
3. Recommendations for improving this approach to Canadian First Nations education?

Blended learning

The idea of blending different learning experiences has been in existence ever since humans started thinking about teaching (Williams, 2003). What has recently brought this term into the limelight is the infusion of web-based technologies into the learning and teaching process (Allen & Seaman, 2010; Clark, 2003). These technologies have created new opportunities for students to interact with their peers, teachers, and content.

Blended learning is often defined as the combination of face-to-face and online learning (Sharpe et al., 2006; Williams, 2002). Ron Bleed, the former Vice Chancellor of Information Technologies at Maricopa College, argues that this is not a sufficient definition for blended learning as it simply implies "bolting" technology onto a traditional course, using technology as an add-on to teach a difficult concept or adding supplemental information. He suggests that instead, blended learning should be viewed as an opportunity to redesign the way that courses are developed, scheduled, and delivered through a combination of physical and virtual instruction, "bricks and clicks" (Bleed, 2001). The goal of this redesigned approach to education should be to join the best features of in-class teaching with the best features of online learning to promote active, self-directed learning opportunities for students with added flexibility (Garnham & Kaleta, 2002; Littlejohn & Pegler, 2007; Norberg, Dziuban, Moskol, 2011). This sentiment is echoed by Garrison and Vaughan (2008) who state that "blended learning is the organic integration of thoughtfully selected and complementary face-to-face and online approaches and technologies" (p.148). A survey of e-learning activity by Arabasz, Boggs & Baker (2003) found that 80 percent of all higher education institutions and 93 percent of doctoral institutions offer hybrid or blended learning courses (Figure 1).

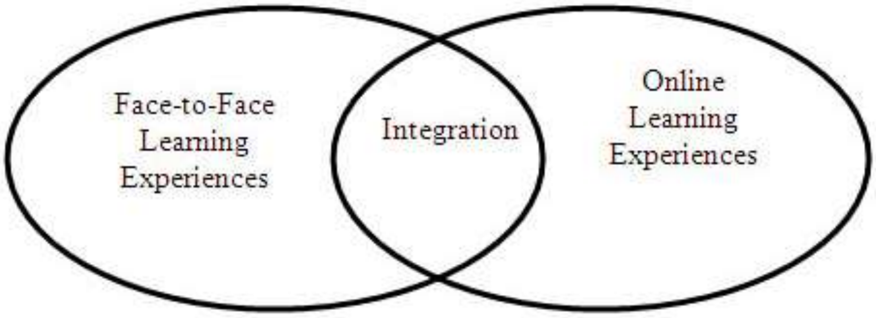

Figure 1: Campus-based blended learning approach

Campus-based environments have their roots in educational systems where classes have been delivered by teachers in synchronous class lecture settings. Initially, blended learning has been used to complement these synchronous lectures through the use of asynchronous discussion forums and learning management systems such as *Blackboard* and *Moodle*. With the advent of synchronous tools, such as *Blackboard Collaborate* and *Adobe Connect*, opportunities have been created to provide students with both synchronous and asynchronous communication possibilities.

Power (2008) has coined the term Online Blended Learning to describe the simultaneous and complimentary integration and implementation of an asynchronous-mode learning environment (i.e. a course management system, or CMS) and a synchronous desktop conferencing environment (i.e. virtual classroom). The Sunchild E-Learning Community framework has further expanded this conception of blended learning by fully integrating face-to-face and online synchronous and asynchronous learning opportunities for their students through the use of mentors at local learning centres and highly qualified online teachers (Figure 2).

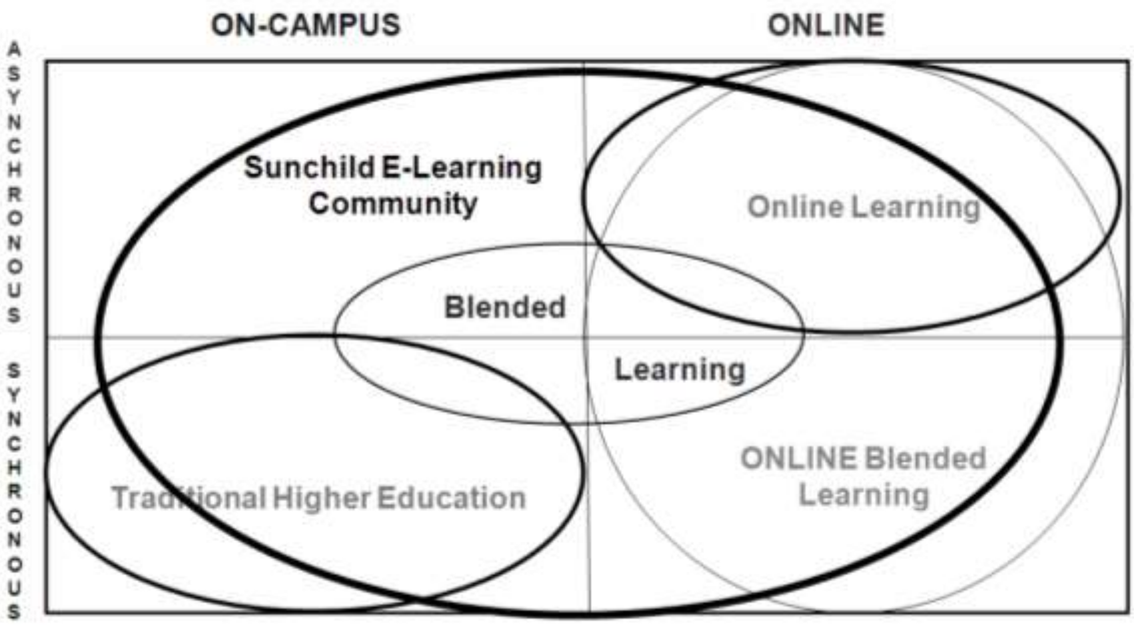

Figure 2: Sunchild e-learning community program framework

Methods of investigation

An action research (Stringer, 1999) and case-based method (Creswell, 1997) were utilized for this study. Gilmore, Krantz and Ramirez (1986) define such a framework as:

> Action research . . . aims to contribute both to the practical concerns of people in an immediate problematic situation and to further the goals of social science simultaneously. Thus, there is a dual commitment in action research to study a system and concurrently to collaborate with members of the system in changing it in what is together regarded as a desirable direction. Accomplishing this twin goal requires the active collaboration of researcher and client, and thus it stresses the importance of co-learning as a primary aspect of the research process. (p.161)

This approach consisted of a mixture of quantitative and qualitative data collection methods. All students enrolled in the Sunchild E-Learning Community program were invited to complete an online survey in the fall 2011 semester and then follow-up online interviews were conducted in December 2011 with four of the students who completed this survey. In the winter 2012 semester, these online interviews were expanded to include seven mentors, two online teachers, and the principal of the program. Two site visits were also conducted (Chinki Adult Education Center and the Calgary Aboriginal Futures Center).

The educational research literature strongly suggests that student engagement is the key to academic success and retention (Astin, 1999; Kuh, 2008; Pace, 1980; Pascarella & Terenzini, 2005). The National Survey of Student Engagement (NSSE) defines student engagement as the amount of time and effort that students put into their academic studies that lead to experiences and outcomes that constitute student success, and the ways that programs allocate resources and organize learning opportunities and services to induce students to participate in and benefit from such activities (NSSE, 2011). The NSSE is constructed on the Seven Principles of Effective Teaching (Chickering & Gamson, 1999):

1. encourages contact between students and teachers,
2. develops reciprocity and cooperation among students,
3. encourages active learning,
4. gives prompt feedback,
5. emphasizes time on task,
6. communicates high expectations, and
7. respects diverse talents and ways of learning

These seven principles are based on over fifty years of educational research (Graham et al., 2001) and they were used to guide the data collection and analysis for this study.

Findings

This section begins with a demographic profile of the student participants followed by a summary of the results for each of the three research questions based on the seven principles of effective teaching framework:

1. What are the advantages of a blended approach to Canadian First Nations education?
2. What are the challenges?
3. Recommendations for improving this approach to Canadian First Nations education?

Demographic and technology profile of student participants

There were three hundred and eight students enrolled in the Sunchild E-Learning Community in the fall 2011 semester. In order to establish a context for the study findings, the initial online survey asked a series of demographic questions (n=24, 8% response rate). Table 1 compares the demographics of students in the Sunchild E-Learning Community to students at a university in Calgary, Alberta who had recently completed a similar survey (Vaughan et al., 2011). The purpose of this comparison is to demonstrate the demographic similarities and differences of students enrolled in the rural Sunchild E-Learning Community program to those attending an urban university.

Table 1: Student comparison of Sunchild e-learning community and Mount Royal University

Student Item	Sunchild E-Learning Community	Mount Royal University
Gender		
Female	68%	55%
Male	32%	45%
Age		
Under age of 24	54%	89%
Over age of 24	46%	11%
Place of Residence		
Living with parents	46%	62%
Living with own family with children	42%	0%
Living alone	0%	10%
Living with roommates or partner with no children	13%	23%
University residence	0%	5%
Employment Status		
Currently not working	83%	23%
Currently working part-time	16%	65%
Currently working full-time	0%	23%

Two-thirds of Sunchild E-Learning Community students were female and one-third were male. The students surveyed ranged in age from 18 to over 41. There appeared to be a bi-modal age distribution with two-thirds of the students between the ages of 15 to 27 and one-third between the ages of 31 to 41 plus. In terms of place of residence, 46% of the students lived with their parents, 42% lived with their own family with children, and 12% lived with roommates or partner with no children. With regards to employment status, 83% of the students were currently not working compared to only 23% of the Mount Royal students (the remainder had either a part or full-time job).

A similar comparison was made between Sunchild E-Learning Community and Mount Royal University students with regards to access to technology and self-reported skills (Table 2).

Table 2: Comparison of technology access and skills between Sunchild e-learning community and Mount Royal University students

Technology Item	Sunchild E-Learning Community	Mount Royal University
Home access to the Internet	37%	100%
Access to high-speed home Internet connection	33%	98%
Have your own a mobile communication device (e.g., cell phone)	62%	90%
Have your own laptop computer	38%	89%
Have your own a mobile communication device with Internet access (e.g., Smart Phone)	29%	82%
Personal Rating of Computer Skills		
Novice (not really comfortable using computers)	0%	5%
Intermediate (comfortable using computers)	70%	59%
Advanced (have developed some expertise and enjoy using a computer)	30%	36%

In terms of technology access, only 37% of the Sunchild E-Learning Community students surveyed had home internet access. Two-thirds of the students had a mobile communication device (e.g., cell phone, Blackberry, iPhone), 38% had their own laptop, and 33% had access to a desktop or laptop computer at home that they share with others. Despite this lack of home and personal access to computer technologies, through participation in the Sunchild program, 70% percent of the students rated themselves as intermediate with regards to their computer skills while 30% rated themselves as experts.

Seven principles of effective teaching practice framework

Principle 1: Good Practice Encourages Student-Teacher Interaction

Frequent student-teacher contact in and out of class is one of the most important factors in student motivation and involvement (Light, 2001). Teacher concern helps students get through rough times and keep on working. Knowing a few teachers well enhances students' intellectual commitment and encourages them to think about their own values and plans (Chickering & Gamson, 1999). The Sunchild E-Learning Community is designed so that students have optimal contact with mentors at the learning centers and the online teachers through synchronous and asynchronous communication systems (Figure 3).

Figure 3: Student and mentor at the Chiniki adult learning center

Mentors

Students interviewed indicated that there is an opportunity to interact with the mentors on a daily basis that helps form a relationship and a bond over time. The mentors commented on how they know what is happening in the student's school and family life and how they gently nudge students forward through encouragement and help. The online teachers stressed that an active mentor is the key to the success of the program. The more active the mentor, the more students they draw to the site and the more they retain their students – the key to academic success.

Online Teachers

The students indicated that the one-to-one interaction in the online tutorials and personal emails from the online teachers really helped them succeed. One student also commented that "I get along with my online teachers because they don't know me, my reputation, and how I've been in the past, how I acted out in high school that gave me a really bad reputations" (Student 2). The mentors stated that Sunchild has "amazing online teachers – they really know their stuff and they are very encouraging with the students" (Mentor 5). The online teachers stressed that "we are here for the students – we are a face on the screen, a voice in the headset – more than just an email message" (Online Teacher 1). And, that "synchronous online communication is the key to establishing relationships with students – without this component it would just be a glorified correspondence program" (Online Teacher 2).

Integration

The students emphasized how important it was for them to integrate both the mentor and online teacher support. For example, "I learn new ideas and concepts in the online tutorials and then I practice them with the mentors help in the classroom" (Student 4). It's "almost like having two teachers for all of my courses" (Student 2). "Pretty well like having a teacher right beside you all the time" (Student 3).

Several of the mentors also commented on the integration of teaching support, "I can listen to the online teacher and then explain the concepts to the students" (Mentor 7). "Having both a face-to-face mentor and online teachers is important to balance student support and perspectives about learning" (Mentor 4). "Students are motivated and encouraged by both the online teachers and mentor to succeed" (Mentor 2).

Mentor - Challenges and Recommendations

The students identified mentors potential lack of educational experience and sometimes not a positive relationship with all students as a couple of challenges. The online teachers also indicated that some mentors are quite hands-off with their students and quite hands-off with the online teachers, which can lead to communication and student progress challenges.

Several students recommended having more than one mentor at each centre so that you can find someone whose personality you can relate to. The online teachers suggested that the mentors receive training and become more active in counselling students about appropriate courses. For example, having students complete basic literacy and numeracy pre-requisite modules before attempting high school level courses.

Online teacher – Challenges and Recommendations

The only challenge identified by students is that sometimes they feel like they have to wait a long time to have their questions to the online teachers answered by email despite the fact that there is a 24 hour response policy in place (except for weekends).

Both online teachers interviewed emphasized that workload was a serious issue. They indicated that to do a good job teaching online you cannot do it full time. "What has happened to some people is that they have actually burned out" (Online Teacher 2).

One of the mentors suggested having online teachers come to each of the sites to meet their students a couple of times each year, "putting an actual face to a name" (Mentor 6). And, the recommendation was made to hire more online teachers and lighten their teaching load.

Principle 2: Good Practice Develops Reciprocity and Cooperation among Students

Learning is enhanced when it is more like a team effort than a solo race (Chickering & Ehrmann, 1996). Good learning, like good work, is collaborative and social, not competitive and isolated. Working with others often increases involvement in learning. Sharing one's ideas and responding to others' improves thinking and deepens understanding. This Sunchild E-Learning Community intentionally emphasizes cooperation and community for everyone involved in the program – students, parents, mentors, online teachers, principal, and administrative staff.

Students

The program and the learning centers are designed to create a cooperative environment for the students. For example, students are able to interact and work with other students while they are at the center. In addition, "they get to participate in real online sessions with other students their age from other reserves. Not with younger students so they feel more comfortable with their learning" (Mentor 1).

The mentors also work hard to provide a sense of community and belonging at the learning centers. "I do lunches with my students so that it becomes more of a community. We do it for special holidays and at the end of each semester. This keeps the students engaged and makes them feel like they are part of something" (Mentor 2). At another center, "we've got a lunch area and a pool table in the basement of our center where students can relax and socialize" (Mentor 3). And, "we're not in the main school so the students feel like they are not going to the regular high school. The students are older and this building feels more like their place – not a traditional school with younger children" (Mentor 5). At the Chiniki Center, "they actually have their own Students Council – so there is some form of community and opportunity to socialize" (Mentor 3).

Mentors and Online Teachers

Both the mentors and online teachers interviewed commented on how they work hard to cooperate and create a community amongst themselves. One online teacher indicated that "the proactive mentors are constantly emailing me with questions – they are really involved with their students – you get to know these mentors and you have a great relationship with them (Online Teacher 2). In addition, "all the mentors and online teachers have Skype so that we can have instant conversations rather than waiting for email" (Mentor 6). One mentor has constructed" a bulletin board at our site that introduces the online teachers and the subjects they teach" (Mentor 4).

Principal

All of the mentors and online teachers were unanimous in their praise for the tremendous support and mentoring provided by the Principal of the Sunchild E-Learning Community. She works very hard to establish a sense of community for the program by always being available for help and coordinating monthly online team meetings with all the mentors and online teachers. Currently, the team is reading and discussing the *Blended Learning in Higher Education* book (Garrison & Vaughan, 2008) during their monthly meetings (Online Teacher 2). Each August, the Principal also organizes and facilitates an annual face-to-face meeting of all the online teachers and mentors in Red Deer before the start of the school year (Mentor 5).

Student - Recommendations
One student interviewed suggested that there should be more face-to-face group work. She commented that "there are lots of students in my online class but for me it seems easier to work in a face-to-face group" (Student 4).

Mentor - Recommendations
Since the mentors work with the students on a daily basis one mentor recommended that "a mechanism should be developed where mentors could have some input about common student learning issues or problems. I think this would help improve parts of some of the online courses" (Mentor 3). Support is already provided to help new mentors establish their learning centers but one mentor also commented on how important it is to include a social context to these centers so that students immediately have a sense of belonging and community (e.g., displaying their work on the walls, creating a student council, creating a lunch and leisure space).

Principle 3: Good Practice Uses Active Learning Techniques
Learning is not a spectator sport (Chickering & Ehrmann, 1996). Students do not learn much just sitting in classes listening to teachers, memorizing pre-packaged assignments, and spitting out answers. They must talk about what they are learning, write reflectively about it, relate it to past experiences, and apply it to their daily lives. They must make what they learn part of themselves. In order to achieve this ideal, Littky and Grabelle (2004) advocate for a learning environment that stresses relevance, rigor, and relationships (3R's of engagement).

Life Skills
In the interviews, all the mentors and online teachers stressed how relevant the Sunchild E-Learning Community learning experience was for the students. For example, "the students are learning so many key life skills through this program such as time management, money management, public relations skills, online and face-to-face communication skills" (Mentor 7). And, "they are learning important technology life skills through their studies – searching, word processing, spreadsheets. They receive one Career & Technology Studies (CTS) credit for doing the online orientation to the program, which is an introductory computer skills module (Online Teacher 1). In addition, "the program teaches students to be more accountable for their own learning. They become independent, mature, and self-directed learners" (Mentor 2).

Technology
The students indicated that they found learning with technology to be very motivational. They also commented on how "the computers at the center work – very few technical or Internet connectivity problems" (Student 3). One of the mentors also stressed how he had "great local IT support from the Band" (Mentor 3).

Online Learning
Several of the mentors described how the online learning component of the program was interactive and visually stimulating for the students. "Students are able to see everything on the whiteboard, write on the whiteboard, speak, or text. It's much more interactive than a conversation" (Mentor 2). "The audio and visual recorded tutorials enable students to pick up where they left off. I have seen first-hand, how this is a very valuable aspect of the program" (Mentor 6)

Technology - Challenges and Recommendation
While the students seemed relatively content with the technology and Internet connectivity at the learning centers the mentors and online teachers identified several challenges and recommendations. The Calgary Urban Center has experienced rapid growth and they identified lack of computers and printers as an issue. "It's sometimes hard to get students to come into our centre when they have to wait for a computer or printer to use" (Mentor 2). At some of the more remote sites Internet connectivity was raised as an issue. "Slow Internet connection – really impacts students' ability to view the recorded tutorial sessions" (Mentor 4).

Several student issues with technology were also raised. For example, "some of the older students initially find the technology to be a barrier – they lack the previous experience and they panic when they encounter logon or tool problems – they sometimes wish they could just use pen and paper and fax in their work" (Online Teacher 2). Or, "sometimes students forget where they saved their work – on the network or on the computer. After students make a few mistakes, they don't make them again" (Mentor 3). And, "wide open access to the Internet. I have found that some students become sidetracked very easily – such as going on YouTube" (Mentor 5).

Numerous recommendations were provided by students, mentors, and online teachers about improving the use of technology to support an active learning environment. One online teacher emphasized that is should be "mandatory that all students complete the online orientation module BEFORE they begin their academic studies – reduce anxiety and frustration and level the playing field" (Online Teacher 1). It was also suggested that "all the sites should have the same level of technology – older sites have older computers while newer sites have newer computers" and that there should be "more on-ground technical assistance – some sites are very isolated while others are right in the middle of Calgary" (Online Teacher 1). Several of the mentors echoed these comments and one indicated that he's been working hard to obtain newer technology "but it's the Band's decision and budget" (Mentor 6).

Two mentors stressed the need for "more printers, we always get students to print out their work just in case something gets lost on the computer. Also, students can take their work home with them as many of them do not have computers in their homes" (Mentor 1). And, another mentor commented that she would like to see the "SCCyber website more user friendly – navigation around the site isn't that easy" (Mentor 6).

Finally, one of the students would like to "find a way to use the online whiteboard without using the computer mouse or keyboard – I find it difficult to show the teacher how I can solve a problem by just using my mouse to write out the answer on a whiteboard" (Student 4). A potential solution maybe the purchase of a *Wacom Drawing Tablet* (http://www.wacom.com/en/Products.aspx) or even an *iPad* (http://www.apple.com/ipad/) for each of the learning centers.

Other – Challenges and Recommendations
The students and mentors both indicated that the Science and Math courses were very demanding. One of the mentors suggested that there should be "extra tutorial time for courses like Science and Math 10. These are heavy courses and there is a lot covered. I think students need some extra time and assistance with these courses" (Mentor 2).

Principle 4: Good Practice Gives Prompt Feedback
Knowing what you know and don't know focuses your learning. In getting started, students need help in assessing their existing knowledge and competence. Then, in classes, students need frequent opportunities to perform and receive feedback on their performance. At various points during courses, and at their end, students need chances to reflect on what they have learned, what they still need to know, and how they might assess themselves. The Sunchild E-Learning Community program places a huge emphasis on frequent and weekly assessment feedback (Figure 4).

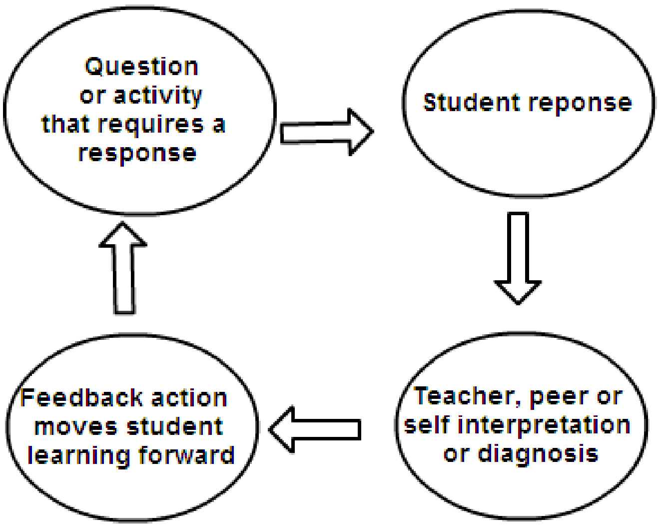

Figure 4: Student assessment feedback loop

Students
Through the use of the online grade book in the *Moodle Learning Management System* the students "have access to their grades online, which is updated every Monday morning. So the students know from Monday to Monday if they are passing or failing a course" (Mentor 1).

Mentors
The mentors are constantly providing students with feedback and checking in on assignment completion. "A week does not go by without me personally checking in on student progress" (Mentor 7). "Any time a student emails a completed assignment to an online teacher it gets copied to the mentor. The mentor also gets a copy of the marked one as well" (Mentor 3). The students commented that this immediate assistance and feedback with questions and any problems with the computers really helped with their academic progress (Student 1).

Online teachers
Students indicated that they can always get an email reply or one-to-one tutorial assistance for difficult questions from their online teachers (Student 3). "All the student assignments that are completed by Thursday are returned to each student by the following Monday with a grade and assessment feedback" (Online Teacher 2).

Principal
If there are any serious academic issues with students the principal of the program will talk to them right away and sort out the problem (Mentor 6).

Integration
The students interviewed described how immediate and weekly feedback from both the online teachers and mentors is critical to their academic success. "If I have a question I get immediate feedback from either the mentor or online teacher – there is no waiting around or confusion" (Student 2). In addition, every Monday the mentors "get a report from the online teachers about each student's progress. It contains two columns – an average for assignments completed and an average for all assignments, including the ones not completed. I then add my comments to the report and email it to the student. I then sit down and review the report with each student each week" (Mentor 2).

Principle 5: Good Practice Emphasizes Time on Task
Time plus energy equals learning. Learning to use one's time well is critical for students and professionals alike. Allocating realistic amounts of time means effective learning for students and effective practices for mentors and online teachers. In the interviews, the students and the mentors stressed how the computers, the learning centers, and the weekly emphasis on organization and scheduling helped them stay focused and on-track with their academic studies. (Figure 5).

Figure 5: Focused student work in the learning centers

Computer-based learning
Some of the students interviewed had encountered conflict with teachers and peers at other schools. They indicated that “when I’m on the computer – I’m focused on just learning not worrying about getting along with other students or teachers” (Student 1). I can “focus on learning not on classroom ‘drama’ – it’s not based on your personality like a normal school” (Student 3)

Learning Centers
For many of the students involved in the Sunchild E-Learning community the home environment is not an ideal place for academic studies. Students commented that the learning centers are a “Safe and quiet place to learn – not like my home” (Student 2). The mentors indicated that they “really work hard to make sure there are no distractions” at the learning center (Mentor 2). “The students can work at their own pace. They get their headsets on and they just focus on their learning. They don’t worry about other people in the room or any other distractions” (Mentor 3).

Organization and scheduling
The mentors provide on-going support for the students with the organization and scheduling of their academic studies. “We help our students to continually stay on track with their studies. I meet with each of my students once a week. We go over where they need to be and where they are with their studies. For example, if they have 9 assignments and only 6 have been handed in, what is going on with the other 3?” (Mentor 2). We also “help the students organize and schedule their high school program – funding forms, weekly schedules and progress reports” (Mentor 6).

Challenges
The only challenge identified for keeping students focused and on task came from students and mentors at the Calgary Urban Centre. They indicated that their learning center needs “more computers and printers – as students often have to wait for access” (Student 1).

Principle 6: Good Practice Communicates High Expectations
Expect more and you will get it. High expectations are important for everyone — for the poorly prepared, for those unwilling to exert themselves, and for the bright and well motivated (Chickering & Gamson, 1999). Expecting students to perform well becomes a self-fulfilling prophecy. The Sunchild E-Learning Community has developed a series of strategies to communicate high expectations to their students (Figure 6).

Figure 6. Learning center wall of success

Wall of Success
At “each of our centers there is a Wall of Success – where student accomplishments are posted and profiled” (Mentor 2). In addition, there is a bulletin board at each learning center that advertises careers, future learning opportunities, and colleges and universities – providing goals for the students to strive for.

Additional Strategies
The mentors indicated that the program uses a combination of strategies to communicate high expectations “deadlines, real online teachers to talk to and get help and encouragement. Sunchild is much more motivating

that just using workbooks on your own" (Mentor 7). And, one of the students commented that "all the support makes me want to step up my game and graduate from high school" (Student 4).

Principle 7: Good Practice Respects Diverse Talents and Ways of Learning

Many roads lead to learning. Different students bring different talents and styles to their studies. Brilliant students in a classroom might be all thumbs in a lab or studio; students rich in hands-on experience may not do so well with theory. Students need opportunities to show their talents and learn in ways that work for them. Then they can be pushed to learn in new ways that do not come so easily. Everyone interviewed commented how the Sunchild E-Learning Community's blended approach to learning supports diverse talents and ways of learning (Figure 7).

Figure 7: Synchronous online tutorial in Blackboard Collaborate

Blended Learning – Flexibility

The blended approach utilized by this program provides students with the flexibility to succeed in their academic studies. "Flexibility for students like myself who are single parents with children under the age of 12. I could still log on from home and continue my studies. I let the mentor know that I was sick but could still connect with the online teachers. If it wasn't for this flexibility I would probably not have graduated with my Grade 12 diploma (Mentor 6). "This program takes the best of face-to-face and online learning to provide flexibility and alternative learning pathways for our students. Sunchild is more than just passing or failing our students. We actually want our students to learn and understand what they are being taught – to take ownership for their learning" (Mentor 2).

Blended Learning – Communication

In the online sessions "we can communicate either by speaking or texting – depending on how comfortable we feel" (Student 3). In addition, "online learning is easier and more environmentally friendly – not a lot of paper" (Student 2).

Blended Learning - Self -pacing

All of the online tutorial sessions are recorded and archived "so students can play them again at their own pace and location – at the center or at home (Online Teacher 1). The students indicated that these "recorded sessions are really helpful because sometimes I forget important points or ideas" (Student 4).

Blended Learning – Challenge and Recommendation

One of the online teachers believes there is a "direct correlation between student attendance in the live sessions and student success in a course" (Online Teacher 2). I would recommend that students should be strongly encouraged to not only attend but to actively participate in these live sessions – either by voice or text chat.

Recommendations – Additional Courses
The vast majority of students, mentors, and online teachers interviewed were satisfied with the current courses offered by the Sunchild E-Learning Community. They indicated that these courses provided a solid foundation for an accredited Alberta High School Graduation Diploma. As the program continues to grow and evolve, recommendations were made for additional life skills, options, and college and university bridging courses.

Life Skills
The mentors and online teachers interviewed suggested that there should be “more basic level knowledge and employability skills courses” (Online Teacher 2). For example, “maybe some more life skills courses like coping with conflict and issues. A lot of our students are having problems at home which keeps them from passing or doing any school work” (Mentor 6). In addition, one mentor suggested “more single credit CTS courses” in order to encourage student success and course completion (Mentor 4).

Options
Several mentors suggested the addition of Fine Arts courses such as Art 10. “There are no Fine Arts courses but maybe in the local community they could find someone to teach them piano or art work” (Mentor 5). In the southern part of Alberta, mentors would “like to see us getting the Blackfoot language courses up and running so that we are covering the languages relevant for our students. Sunchild now has sites in all three Blackfoot reserves in Alberta” (Mentor 2).

College and University Bridging Courses
One mentor indicated that “we have some adults who have finished high school who would like to come back but we don’t have any College courses to offer them right now” (Mentor 1). Another mentor mentioned that there are some bridging courses and programs to “NAIT and DeVry but that these should be expanded to other Alberta colleges and universities” (Mentor 6). Hopefully, as a result of this program evaluation study Mount Royal University will become a more active bridging partner.

Conclusion and recommendations

> If students learn to make education a priority they are going to succeed in life. (Mentor 3)

The study participants indicated that the blended approach of the Sunchild E-Learning Community program through the deliberate and intentional integration of mentors at local learning centers with online teachers, who provide synchronous tutorials through the use of a web-based learning management system and conferencing tool, was the key to academic success. They also emphasized how this blended approach helped First Nations students overcome major learning challenges such as remote locations, lack of access to digital technologies, high speed internet access, and quality teachers. An evaluation of this program through the lens of the *Seven Principles of Effective Teaching* (Chickering & Gamson, 1999) clearly demonstrates that this task is being accomplished.

Principle 1: Good Practice Encourages Student-Teacher Interaction

Synchronous and asynchronous communication technologies are being used by students in the Sunchild E-Learning Community to increase access to their online teachers and mentors, help them share useful resources, and provide for joint problem solving and shared learning that is being combined with face-to-face mentoring at the learning centers. These communication technologies are strengthening online teacher interactions with all students, but especially with shy students who are reluctant to ask questions or challenge the teacher directly. These students find that it is often easier to discuss values and personal concerns in writing rather than orally, since inadvertent or ambiguous nonverbal signals are not so dominant.

The roles and responsibilities of the online teacher in this program can become overwhelming and a recommendation has been made to have each of the online teachers log their daily activities for a one week period. Then, at one of the monthly team meetings the results can be shared and strategies developed for managing the workload of an online teacher in the Sunchild E-Learning Community.

Principle 2: Good Practice Develops Reciprocity and Cooperation among Students

The Sunchild E-Learning Community strategically works at creating a cooperative learning environment amongst the students, parents, mentors, and online teachers. The focus of the program is on self-paced learning but the study participants suggested that communication and information technologies could be used to support additional opportunities for study groups, collaborative learning, group problem solving, and discussion of assignments.

In addition, many of the students and mentors emphasized how important it is to create a sense of community at the learning centers (e.g., displaying student work on the walls, creating a student council, creating a lunch and leisure space). A recommendation has been made to have senior mentors travel to new sites to help the new mentors establish their learning centers.

Principle 3: Good Practice Uses Active Learning Techniques

The range of technologies that the Sunchild E-Learning Community uses to encourage active learning is extensive. In the past, apprentice-like learning has been supported by many traditional technologies: libraries, laboratories, art and architectural studios, athletic fields. Newer digital technologies can now enrich and expand these opportunities – especially for those students located in rural and remote parts of Alberta and the Northwest Territories. For example:

- Supporting apprentice-like activities in fields that themselves require the use of technology as a tool, such as statistical research and computer-based music, or use of the Internet to gather information not available in the local library.
- Simulating scientific techniques such as helping chemistry students develop and practice research skills in “dry” simulated laboratories.
- Helping students develop insight. For example, students can be asked to design a radio antenna. Simulation software displays not only their design but the ordinarily invisible electromagnetic waves the antenna would emit. Students change their designs and instantly see resulting changes in the waves. The aim of this exercise is not to design antennae but to build deeper understanding of electromagnetism.

Many of the students enrolled in this program also have their own mobile devices and a recommendation has been made to have them use these devices to document and record their learning in their local communities. For example, they could use their phones to take pictures and record videos that could then be used in the creation of digital stories for course assignments (*Center for Digital Storytelling* - http://www.storycenter.org/).

Principle 4: Good Practice Gives Prompt Feedback

The combination of a learning center mentor and online teacher for each course ensures that all students enrolled in the Sunchild E-Learning Community receive timely and regular feedback about their academic studies. Computers also have a growing role in recording and analyzing personal and professional performances. Teachers can use technology to provide critical observations for an apprentice; for example, video to help a novice teacher, actor, or athlete critique his or her own performance. Teachers (or other students) can react to a writer’s draft using the “hidden text” option available in word processors: Turned on, the “hidden” comments spring up; turned off, the comments recede and the writer’s prized work is again free of “red ink.”

In addition, as Alberta Education moves toward portfolio assessment strategies, computers can provide rich storage and easy access to student products and performances. Computers can keep track of early efforts, so teachers and students can see the extent to which later efforts demonstrate gains in knowledge, competence, or other valued outcomes. Performances that are time-consuming and expensive to record and evaluate — such as leadership skills, group process management, or multicultural interactions — can be elicited and stored, not only for ongoing critique but also as a record of growing capacity.

Principle 5: Good Practice Emphasizes Time on Task

The Sunchild E-Learning Community program allows students to work at their own pace in a safe environment with constant monitoring of their progress. The mentors and online teachers interviewed indicate that some students have problems completing their assignments in a timely fashion and thus, have to hastily complete a large portion of them at the very end of the semester. Strategies have been put in place to enforce regularly-distributed deadlines that encourage students to spend time on tasks and help them avoid procrastination. These deadlines also provide a context for regular weekly contact with the mentors and online teachers.

Principle 6: Good Practice Communicates High Expectations

This program does an excellent job of communicating high expectations and publicly praising students through the *Wall of Success* (student course completion certificates) at each learning center. Communicating high expectations for student performance is essential. An additional way for teachers to do this is to give challenging assignments. For example, assigning tasks that require students to apply theories to real-world situations rather than remember facts or concepts. This case-based approach involves real-world problems with authentic data gathered from real-world situations.

Another way to communicate high expectations is to provide examples or models for students to follow, along with comments explaining why the examples are good. Teachers can provide examples of student work from a previous semester as models for current students and include comments to illustrate how the examples met the required expectations. In addition, the online teacher can provide examples of the types of interactions she or he expects in the discussion forum. One example would be to provide an exemplary posting while also providing an example of what *not* to do, highlighting trends from the past that she or he would like students to avoid.

Principle 7: Good Practice Respects Diverse Talents and Ways of Learning

Finally, the Sunchild E-Learning Community clearly demonstrates how communication and information technologies can be used to support different methods of learning through powerful visuals and well-organized text; through direct, vicarious, and virtual experiences; and through tasks requiring analysis, synthesis, and evaluation, with applications to real-life situations. These digital tools are also being used to encourage self-reflection and self-assessment. In addition, technologies are being used in this program to help students learn in ways they find most effective and broaden their repertoires for learning. The technologies, with the mentor and online teacher's support, are supplying the structure for students who need it while leaving assignments more open-ended for students who don't. Fast, bright students can move quickly through materials they master easily and go on to more difficult tasks; slower students can take more time and get more feedback and direct help from the online teachers and mentors.

Finally, every Sunchild E-Learning Community student who participated in this study commented on the "passion and commitment" that the mentors, online teachers, and administrators involved in this program had for student success. They all emphasized that the Sunchild E-Learning Community was "making a difference for their lives". This enthusiasm for learning is definitely infectious and it is strongly recommended that more government departments, educational institutions, and corporations partner with this program in order to expand the positive impact on the lives of First Nations students in Canada.

Risk assessment for human and animal diseases is performed to clarify pathways that may result in disease, and estimate the likelihood of this outcome in specific settings; the outputs are typically used to inform decisions and support policy development. It is often performed using a structured process of elicitation of opinion from subject experts, which aims to minimise the inherent element of uncertainty due to the subjective nature of elicitation. User-friendly software tools can generate insights into risk perception of assessors, elicitation of expert opinion and quantitative estimation of risk. Such tools were incorporated into an online postgraduate course on risk analysis delivered to 36 veterinarians across South Asia. The activities developed to apply these tools required careful staging and scaffolding within the course framework. They highlighted the importance of good coordination and effective communication between the assessors, as well as with the course tutors.

Keywords: risk analysis; risk perception; cognitive maps; network analysis; online learning.

Introduction

The rate of emergence and global spread of new, highly infectious diseases such as severe acute respiratory syndrome (SARS), avian influenza (H5N1) and H1N1 influenza is accelerating (Jones et al., 2008). A common feature of these diseases is that they originated in animal populations before crossing the species barrier to infect humans. Timely identification of such novel infections is essential to implement measures for preventing their spread. This can be challenging for a number of reasons. Firstly, differentiating such new infections from known infections can be difficult, especially if the symptoms are quite generic ("flu-like"). Secondly, their diagnosis requires the presence of suitably skilled human and animal health professionals, as well as adequate facilities and resources. A third prerequisite is the effective coordination between public health and animal health professionals, within as well as between countries. The rapid globalisation of diseases such as SARS and H1N1 influenza has exposed shortcomings in all three of these areas. This has mobilised substantial investment to increase capacity. A key perceived need is the strengthening of cross-sectoral collaboration between doctors and veterinarians, an approach known as 'One Health' (Zinsstag et al., 2011); the foundation of effective action begins with education (Conrad et al., 2009; Osburn et al., 2009).

In 2010 Massey University launched a 'One Health' programme in Asia to strengthen the management of current and emerging human and animal diseases (Vink et al., in press). This programme provides formal training of public health doctors and veterinarians through two Masters degrees: a Master of Public Health (Biosecurity) and a Master of Veterinary Medicine (Biosecurity). The first cohort of students, who commenced their studies in May 2010, consisted of 70 doctors and veterinarians with relevant experience in disease control activities from Afghanistan, Pakistan, India, Bangladesh, Nepal and Sri Lanka. Equal numbers of doctors and veterinarians were enrolled, the objectives being a) to strengthen technical capacity, and provide a unified epidemiological lexicon, b) to foster interaction, communication and active collaboration between the professions and between the participating countries, c) to establish an effective professional network that will be able to bring into practice the principles of 'One Health', and d) to improve the candidates' competence at using information and communication technologies, and confidence in working in an online environment. The Masters programmes require completion of eight courses, as shown in Figure 1. Seven of these are taught entirely online, using the Moodle Learning Management System (LMS) (Moodle, 2012); the remaining course (the fourth of the foundation courses) is a combination of online and face-to-face training. The first four courses provide a foundation in epidemiology and are common to both degrees. The remaining four courses address specialised topics related to human or animal health.

This paper presents a selection of interactive learning activities that were integrated into the veterinary specialty course entitled "Risk and Decision-making During Disease Outbreaks" (Figure 1). In the subsequent section, we will summarise the aims, pedagogical considerations, design and structure of the course. This will be followed by a description of three specific activities, successively defining the objectives, implementation and outcomes of each. The paper will conclude with a general discussion on how these activities contributed towards achieving the course aims.

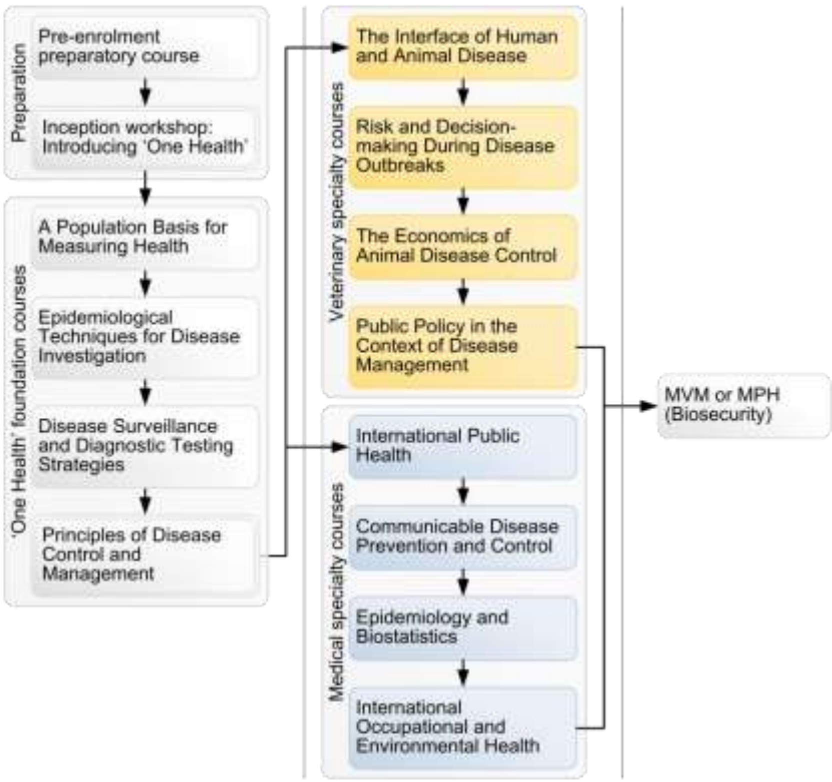

Figure 1: Programme structure of the MVM (Biosecurity) and MPH (Biosecurity) programme. The activities described in this paper fall within the second course in the sequence of veterinary specialty courses, "Risk and Decision-making During Disease Outbreaks".

Considerations informing course design and structure

Risk assessment is performed for human and animal diseases to clarify and quantify pathways that may result in disease, and estimate the likelihood of this outcome in specific settings. The outputs are typically used to inform decisions for the management and control of disease. In analogy with evidence-based medicine, the risk assessment process strives to make use of the most reliable and current knowledge. We can distinguish between explicit knowledge (which is recorded or quantified) and tacit knowledge (which is individual and experiential) (Sandars and Heller, 2006). As the amount of available explicit knowledge on which to base an assessment of risk is often limited, structured techniques have been developed to incorporate the tacit knowledge held by "subject experts". This conforms to the social constructivist view of knowledge, which holds that the knowledge base used for decision-making is not static, but is constantly being expanded and augmented by information-sharing and incorporation of tacit knowledge. This is an integrative process: learners are actively attempting to "update" meaning (Siemens, 2005) and are "learning by doing" (Harasim, 2000). The constructivist theory has led to the concept of "communities of practice" consisting of individuals or members who actively contribute to and expand this collective knowledge base. Such communities can be formally or informally structured, and can meet face-to-face or virtually (Sandars and Heller, 2006).

The course aims were to enable students to formulate risk pathways that may result in disease, estimate the likelihood of this outcome, and utilise these outputs for decision-making. A key objective of the course design was to implement "active" modes of learning which encouraged small-group work and active collaboration. Thirty-six students from Bangladesh, India, Nepal, Pakistan and Sri Lanka were enrolled and grouped into six groups with as diverse a membership as possible in terms of nationality, professional experience and ability. This strived to foster a sense of community of practice, which is reflective of the environment within which risk assessments are carried out in reality. One tutor supported each group when they undertook specific activities; at other times the course coordinator (the second author) provided student support. She also oversaw the delivery of the course, and was involved with overall course assessment and evaluation.

The course was delivered online over a six-week period with a study load of about 20 hours per week. All study materials were made available in the Moodle course, including readings and resources; in addition, all students had full access to the Massey University library. Intensive use was made of native Moodle functionality to perform a combination of individual and group work, including discussion forums, lessons, quizzes and questionnaires. To carry out the specific risk assessment exercises, use was made of additional software tools which were embedded as seamlessly as possible into the LMS. As the course was delivered over a compressed time period, the sequence of content and activities was quite rigidly staged. To ensure students could plan for and engage in the synchronous and asynchronous group activities, they were informed of key calendar dates one month before the course started, and upon course commencement were presented with a clear 'roadmap' that outlined activities and assessment dates. Assessment consisted of a combination of individual and small-group outputs. The main assignment (50% of the course total) consisted of an individual risk assessment performed by the student on a topic of his or her own choosing, applying the techniques taught in the course. The activities described below counted for a total of 30%, with the remainder made up of quizzes and the student's participation in the small-group activities.

Course activities

Three specific activities are described in this section. Each made use of a specific software tool. The activities represented a logical sequence, namely:

- Ranking of disease hazards and agreement between assessors, to illustrate the importance of discussion for overcoming ambiguities in individual risk perception.
- Cognitive mapping of a disease outcome, to illustrate differences in perception and outlook, even when developed as a group, that is, that different "communities of practice" will reach different endpoints.
- Formal specification of a risk model, to quantify the likelihood of a disease outcome under different conditions.

The first two activities were performed in groups, while the third was individual.

Risk ranking and risk matrix development

Definitions and objective
The central concept of a risk matrix is that the likelihood and consequence of disease events are individually scored on a discrete scale by a number of assessors. These descriptors are then used to quantify the level of risk. When repeated for different disease hazards, the hazards can be ranked by risk, and the variability of the risk scores between the assessors can be measured. As the categories on which the scales are based are descriptive, this process is qualitative. This can hinder interpretation, reducing the level of agreement; a process that is referred to as linguistic uncertainty (Regan et al., 2002). Typically, several rounds of risk scoring and discussion are needed to satisfactorily deal with the problems of language and interpretation.

The objectives of this activity were to emphasize problems associated with myopia and overconfidence in performing risk analysis, and to instil an appreciation of the capacity of communication and discussion to buffer against these problems. This demonstrates that it is unwise to rely on the perception and tacit knowledge of the individual, and that even within a group, an iterative process is required to refine the analysis.

Implementation

The activity was structured in a similar fashion as described by Carey and Burgman (2008). In a questionnaire in Moodle, students were asked to qualitatively estimate the consequences associated with eleven infectious animal diseases. Each disease was assigned a numeric score ranging from 1: Insignificant to 5: Catastrophic. Subsequently, the students were asked to estimate the likelihood of these diseases occurring, ranging from 1: Rare to 5: Almost certain. The results were compiled into a risk matrix using Subjective Risk Assessment, a Flash-based tool (Australian Centre of Excellence for Risk Analysis, 2012). Outputs for each group were made available, including a correlation matrix, which measured the level of agreement between each pair of students in the rank order of risk posed by the eleven disease hazards (Figure 2) and a hazard ranking graph, which ordered the disease hazards by magnitude of risk while also displaying the variability of the responses for each disease (Figure 3).

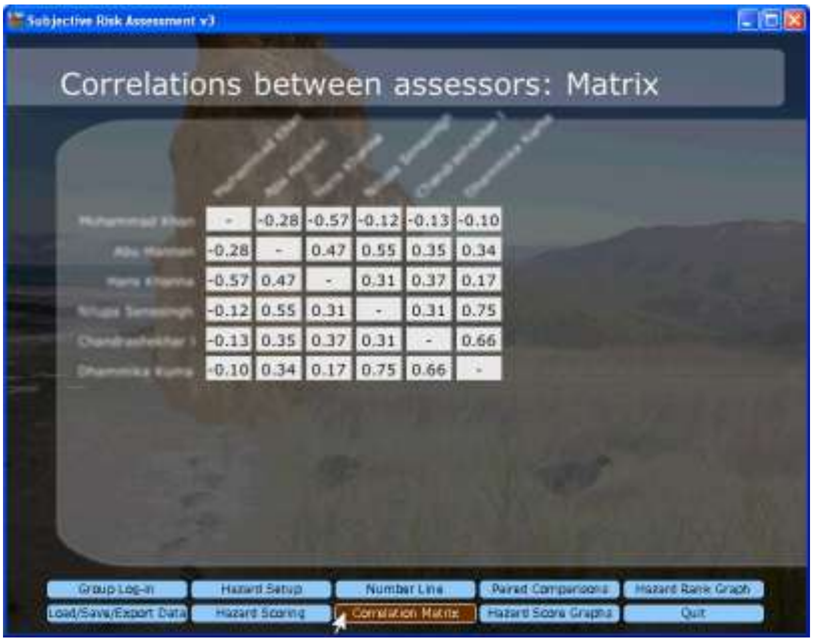

Figure 2: Screenshot of the Subjective Risk Assessment interface, showing the rank correlation matrix between six students in one student group. The scores range from 1 (perfect agreement in rank order) to -1 (complete disagreement), with 0 indicating the level of agreement that could have arisen purely by chance.

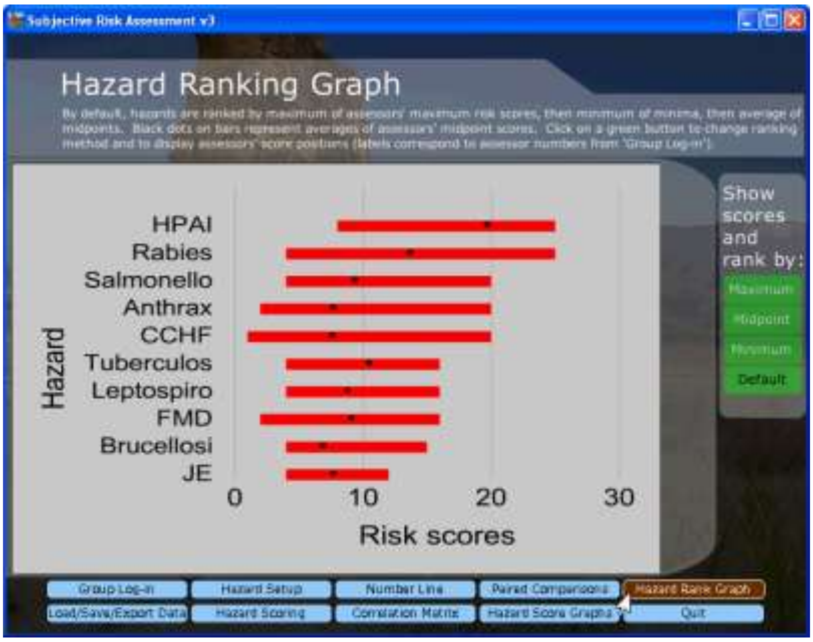

Figure 3: Screenshot of the Subjective Risk Assessment interface, showing the hazard ranking graph for the top ten of eleven diseases of one student group.

In a grouped Moodle discussion forum, students were asked to interpret and discuss the results. They had the opportunity to directly discuss their scores with whomever showed poor agreement to themselves. Subsequently, the sequence of steps was repeated to assess the consistency of the ranking, and whether the agreement between the students had improved.

Students attributed poor agreement entirely to the fact that groups included members from different countries within South Asia, representing a diverse range of backgrounds. To show that these factors could not explain all the variability, the responses of the two questionnaires were also used to generate five country risk matrices.

Outcomes
The level of agreement in the first round of assessment was generally poor; there were substantial differences in the risk rankings of the disease hazards, as well as in the variability in the perceived risk of each hazard.

In the discussions that followed in the Moodle forums, the six groups generated 187 discussion threads with over 300 comments posted over a four-day period. However, while the hazard rankings in the second round of assessment were somewhat more consistent, and the within-group variability did decrease, the magnitude of the effect was not substantial. For the country-level groups, the students expected the rankings to be more consistent than the regional groups, with smaller variability; this was not the case.

In summary, no clear patterns emerged. This result can be primarily attributed to linguistic uncertainty (Carey and Burgman, 2008), that is, uncertainty arising from inconsistent interpretation of words, or different or imprecise meanings of words. This was alluded to in the discussions, in which students mentioned that they found it difficult to assign scores to consequence or likelihood in such a general context.

Cognitive mapping of a disease

Definitions and objective
Cognitive maps, which were introduced in the 1970s by Robert Axelrod (1976), are graphical tools for organizing and representing knowledge, and reflect a ‘narrative’ of cause and effect (Novak and Cañas, 2006). They are directed graphs in which nodes represent key concepts, and interconnecting edges represent causal relationships. They are developed following a process of elicitation, which involves selecting relevant concepts, and specifying the direction and sign (positive or negative) of the associations between the selected concepts (Maule et al., 2004). Cognitive maps have been extensively used in education, including in the medical field (Pinto and Zeitz, 1997; Cañas et al., 2003). In medical education, they were found to assist learning for causal mechanisms in the development of disease (Kumar et al., 2011).

In the context of disease causation, it is customary to define an outcome (disease) and putative factors which influence the risk of this outcome occurring. Cognitive maps can effectively visualise the complex and dynamic processes that lead to disease, incorporating factors which are directly related to the outcome (e.g. an infectious agent) as well as factors exerting more indirect effects (e.g. social, cultural and economic drivers). As a consequence of inherent differences in perceptions and outlook, it is inevitable that different people will construct different cognitive maps for the same problem, even when presented with a common set of defined concepts. Elicitation within a community of practice representing multiple stakeholders draws on collective insights, knowledge and experience: this can improve and prioritise exposure pathways. The collaborative nature of elicitation can reconcile different perspectives and reduce linguistic misunderstanding through clear articulation and communication of causal pathways.

The objective of this exercise was to demonstrate that, even when constructing cognitive maps for the same outcome and starting with the same set of factors, and communicating in real time rather than asynchronously, there is substantial variability in the final maps produced; in other words, that the communities of practice represented by the groups had developed distinct ideas and perceptions.

Implementation
This activity was performed as a combination of small-group and individual activities. The disease chosen was rabies, at it has serious implications in human and animal populations, and is prevalent throughout the region in which the course was taught. Consequently, all students had good understanding and knowledge of the disease. Use was made of the IHMC CmapTools software (Institute for Human and Machine Cognition, 2012). A CmapServer was installed on a web server at Massey University, and used to develop the cognitive maps. The students downloaded and installed CmapTools on their laptops, and connected to the CmapServer (Figure 4).

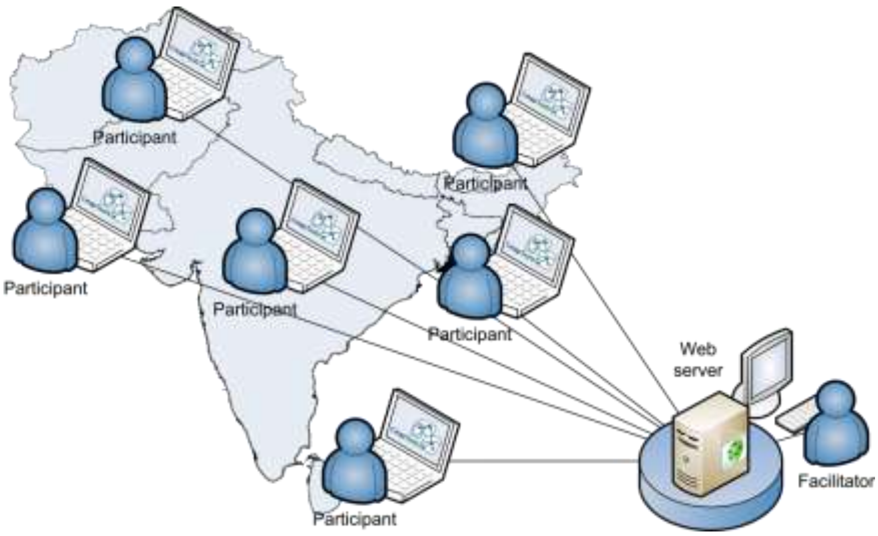

Figure 4: Schematic diagram of the cMapTools activity. One facilitator mediated two synchronous sessions with an average of six participants from throughout the region.

Each of the six student groups could access a folder on the server (Figure 5), which contained a cognitive map containing an outcome node (a human case of rabies, shaded black), and a "parking lot" of concepts: 20 or so risk factors (shaded blue) and six management interventions (shaded green). The maps were developed by the groups using the IRC facility which enabled synchronous collaboration. At appointed times, the students accessed their group map to discuss its development. The group tutor moderated the discussion and followed the lead of the students to construct the map, using the available concepts. To avoid excessive complication, groups were asked to include no more than two management options and six to eight factors. Groups had the option of defining any missing concepts, if they considered these to be essential to discerning the merit of alternative management interventions. The cognitive maps were developed in two sessions of up to two hours each.

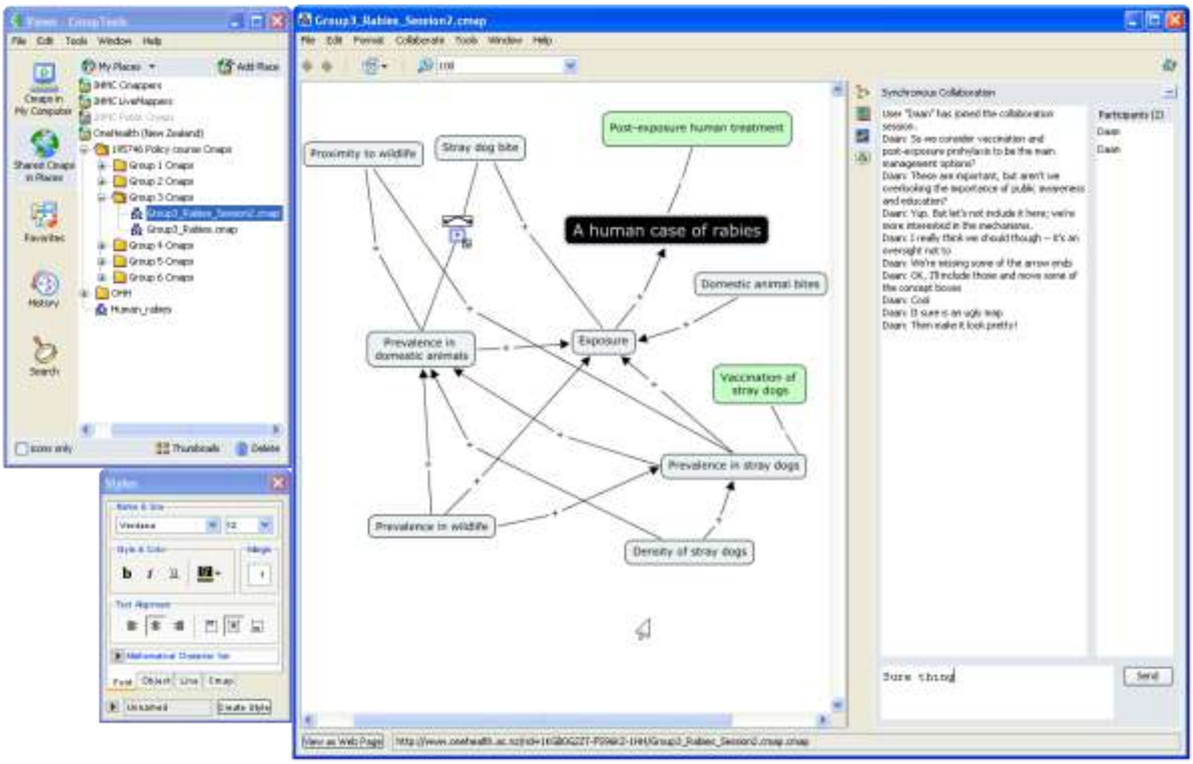

Figure 5: Screenshot showing the cMapTools interface, including the location of the server (left top), formatting dialog (left bottom), main user interface (main panel) with real-time IRC.

After finalisation of the maps, they were uploaded and shared to all students. As part of their assessment, students were asked to constructively review the output of one other group.

Outcomes

As expected, there were substantial differences between the cognitive maps produced by the six groups, in terms of the overall structure (which included linear and hierarchical causal pathways and maps characterised by high interconnectivity and multiple feedback loops) as well as in the number and selection of concepts chosen. The activity was effective in that it demonstrated the variability between groups; it did help to structure thinking, leading to the definition of exposure pathways and mechanisms; and restricting the number of concepts stimulated discussion on which interventions and risk factors to prioritise.

Constraints of this activity included the logistic requirements (installation of CmapServer, setting up for the activity, providing detailed and accurate installation information to the students); the time differences between New Zealand and the five countries; and limitations in internet connectivity, which made participation very difficult for a small number of students.

CmapTools was voluntarily utilised by students in successive courses in the programme, in different assignments; this indicates that the software was considered user-friendly and insightful.

Quantifying risk by specification of a probabilistic model

Definitions and objective

The methods and models considered up to this point were qualitative in nature, or relied on qualitative inputs. As described above, cognitive maps can provide a loose structure for articulating perspectives and pathways. In addition, they can provide a visual model which can form a basis for the specification of a quantitative model, i.e. one in which the inputs and outputs are expressed numerically (Maxwell and Buede, 2003; Mingers and Rosenhead, 2004). The objective of this third activity was to introduce one method of specifying a quantitative model. Such models can easily become mathematically complex. However, the software used for this activity enabled graphical specification of the relationship between variables. This was followed by entry of input values; the software then computed the output value.

Implementation
As the objective was to familiarise the students with the software, this activity was implemented in Moodle as an individual lesson, rather than as a group activity. The starting point was a simplified cognitive map representing the relationship between several concepts and the occurrence of a human case of rabies (Figure 6).

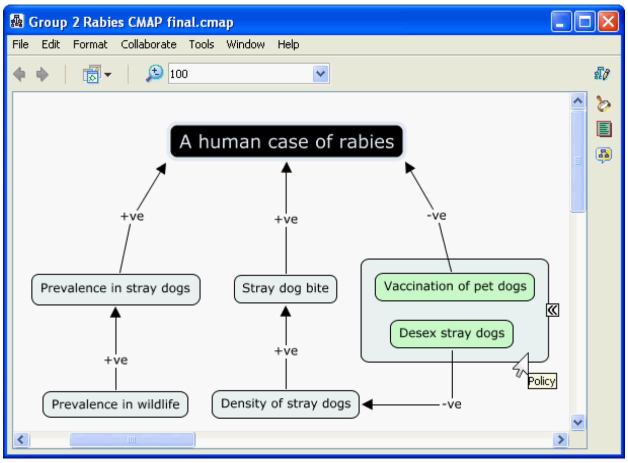

Figure 6: Simplified cognitive map which was used as a basis for quantifying the risk probabilities.

The activity made use of specific software called Netica (Norsys Software Corp., 2012) which enabled the students to replicate this cognitive map, and assign probabilities to the levels of each concept (Figure 7). The software used probability theory to estimate the likelihood of the outcome (a human case), for each of four policy conditions under consideration. All input values were given. Students were asked to update the model by altering parameters and recalculating the estimated outcome.

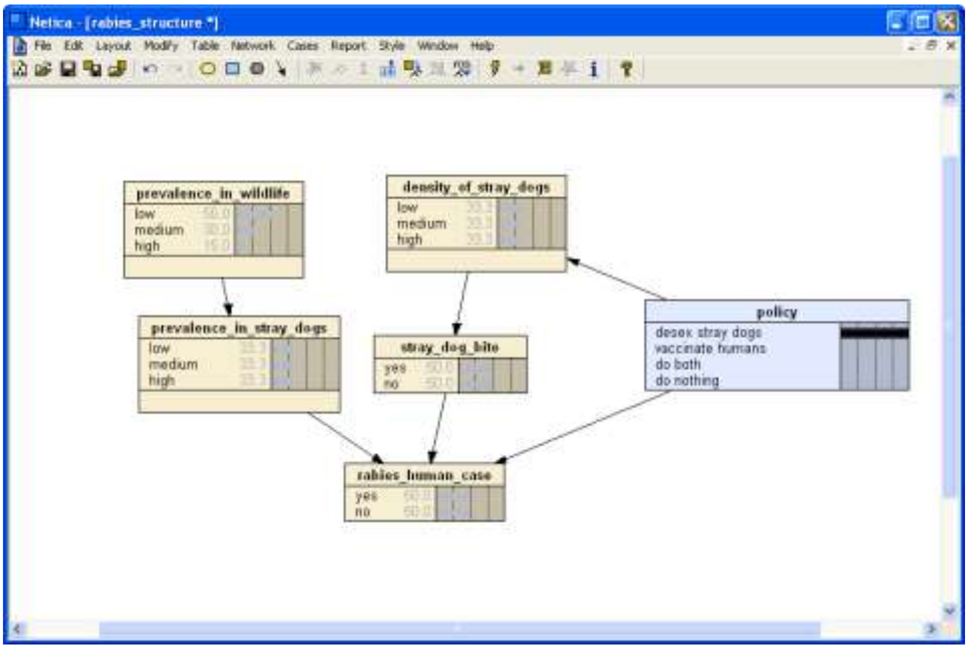

Figure 7: Screenshot of the Netica user interface, showing the network of factors leading to the outcome (human case of rabies). The blue node represents a decision node: for each of the four policy options, the likelihood of an individual person contracting rabies is estimated, given the estimates entered for the other factors.

Outcomes
As this activity illustrated a more advanced concept, it was incorporated into the course as an individual activity, and successful completion was not assessed. However, it was felt to be relevant for inclusion as it

- introduced the students to quantitative methods for risk assessment;
- extended the more advanced students; and
- allowed students with a specific interest in this field to benefit from this ‘state of the art’ material.

General discussion

Establishing this Master degree programme was challenging from a number of perspectives. Firstly, developing a programme tailored to the evolving and fast-developing concept represented by ‘One Health’ meant that the curriculum and the course content had to be designed and built from the ground up. Secondly, online learning was a new experience for almost all the South Asian students, the teaching model was unfamiliar to most, and a large range in the students’ pre-knowledge and experience needed to be accommodated.. Thirdly, the technical aspects of delivering online distance education into a region with highly variable internet availability required careful consideration.

The concept of ‘One Health’ is, by definition, highly multidisciplinary, spanning human, animal and environmental health. In spite of its complexity, support for this concept has grown exponentially in recent years. One reason for its appeal is that it explicitly aims to counteract the divergence of the human, animal and environmental health professions arising from increasing specialisation. Consequently, the leading objectives of this programme were to establish a consistent lexicon and mastery of relevant competencies. Key strategies to achieve this were to teach into a common learning space, and to establish effective communication and collaboration between students from the different countries. A consistent approach for bringing this into practice was the incorporation of relevant, engaging and multifaceted case studies, which required completion of a set of interactive activities, where applicable in a small-group setting. Students were encouraged to make the best possible use of various information domains, including traditional sources such as the University library, but extending to the internet as well as the knowledge and experience held by the participating students themselves. Our experience has been that online learning lends itself organically to the ‘One Health’ approach: De Laat et al. (2006) comment that the field of networked learning, too, is increasingly interdisciplinary and draws upon theoretical perspectives from the domains of education, the social sciences, computer sciences and linguistics. Sandars (2009) succinctly reviews the changing needs and competencies required for the medical learners of the future, and endorses Siemens’ (2005) approach of ‘connectivism’ as a means of identifying and linking information from multiple sources into a dynamic personal knowledge base.

In the risk assessment course presented in this paper, human and animal rabies in South Asia was chosen as an appropriate case study due to its regional relevance and impact. The learning activities that were developed made use of several software tools embedded into the LMS to facilitate the application of the analysis of risk. These activities consisted of a mix of small-group and individual work; a key objective was to establish groups of students from a wide range of countries, professional expertise and experience as “communities of practice”. As there is a relative paucity of verifiable information (explicit knowledge) on the case study in question, this approach was especially important to utilise the tacit knowledge held by these groups for the risk assessments. In addition, this approach closely reflected the sequence of techniques which is followed when risk assessment is performed in actuality, and thus presented a learning experience that was intended to feel “real”. By following this natural sequence of steps, we could demonstrate and highlight constraints and limitations. The first exercise in subjective risk analysis was designed to illustrate the importance of discussion for overcoming ambiguities in language and individual risk perception, and overconfidence in individual opinion. Subsequently, developing cognitive maps as a group activity emphasized the differences in perception and outlook between groups or “communities”. Using a simplified cognitive map as a starting point, the specification of a formal risk model showed how the likelihood of a disease outcome could be quantitatively estimated.

A number of additional activities were incorporated into the course, but were omitted from this paper. For instance, after the specification of the quantitative model, a master class in the elicitation of expert opinion, using a Delphi technique (Linstone and Turoff, 2002), was organised as a teleconference. In two facilitated sessions, panels of eight to twelve student “experts” strived to reach a consensus of opinion on five key questions related to rabies. The scenario was set in a country from which there were no students (Bhutan), to ensure that no students considered themselves to be more highly qualified than others.

To implement the activities within this course over the six-week period of delivery, careful staging within the course framework was required, as well as providing appropriate scaffolding to individual students. This relied on clear communication and effective coordination on between the course tutors and students. The use of the software tools was very highly rated in the course evaluation questionnaire, although a number of students found the subject and content challenging. In addition, the collaborative nature was appreciated, particularly the synchronous group communication sessions. The largest constraints stemmed from difficulties in communication. Firstly, limitations in internet connectivity, speed and reliability made it difficult for a number of students to participate fully in the synchronous sessions. The second constraint was language-based: it was evident that linguistic uncertainty not only applied to risk-related concepts, but also extended to some students' ability to perform the activities! From the submitted individual assignments, it was clear that most students had grasped the fundamental concepts of risk assessment, and a number submitted excellent assignments. Three students failed the course, due primarily to insufficient time spent studying rather than a lack of ability.

Conclusion

The software tools described in this paper have been successfully used for teaching risk assessment in a face-to-face delivery mode. However, integrating the combined set of these tools coherently into a fully online learning environment, and supporting this with the native functionality of the LMS to facilitate learning, extended the utility of these tools and enabled students to understand the contexts in which they should be applied. This enabled 'state-of-the-art' techniques in the field of risk analysis to be easily incorporated into the course.

The importance of power dynamics in the development of asynchronous online learning communities

Panos Vlachopoulos
The Centre for Learning Innovation and Professional Practice
Aston University

This research explored how a more student-directed learning design can support the creation of togetherness and belonging in a community of distance learners in formal higher education. Postgraduate students in a New Zealand School of Education experienced two different learning tasks as part of their online distance learning studies. The tasks centered around two online asynchronous discussions each for the same period of time and with the same group of students, but following two different learning design principles. All messages were analyzed using a two-step analysis process, content analysis and social network analysis. Although the findings showed a balance of power between the tutor and the students in the first high e-moderated activity, a better pattern of group interaction and community feeling was found in the low e-moderated activity. The paper will discuss the findings in terms of the implications for learning design and the role of the tutor.

Keywords: power dynamics, online discussions, learning design, online tutors, social network analysis

Introduction

Student-directed learning has been featured in research within the expanding field of online learning (e.g. Boud, 2006; Comeaux, 2002; Harasim, 1990; Hiltz, 1994; Jonassen, et al., 1995; Wheeler, 2002) for a number of years now. Central to the discussions about student-directed learning is the issue of 'power and student-centeredness' in an online environment, where students and tutors interact online within a fixed curriculum (Boud, 2006). Boud discussed the evolution of the concept of student-directed learning and concluded that 'power is not a zero sum game to be shifted from teacher to student; the goal of this type of learning was not to move the power from teachers to students but to recognise ways in which it was exercised within different teaching and learning practices' (2006: 31). Self-directed learning has at its core the study of how adult learners exercise power and control over their own educational activities (Brookfield, 2005). The issue of power, however, was not found to be of significant importance in the literature of online learning to date, with a few exceptions. For example, Jones (1995:20) was very clear about the importance of considering the issue of power in online discussions. He wrote that 'just because the spaces with which we are now concerned are electronic there is no guarantee that they are democratic, egalitarian or accessible and it is not the case that we can forgo asking in particular about substance and dominance' (20). More recently, Anderson (2006), who conducted a study on writing power in online discussions, found that students are more concerned in 'satisfying' their tutors than with shaping their own learning in their replies. He called for more focused research in the area of power dynamics online with a particular focus on how learning design can create the conditions for student-directed learning. This paper attempts to offer a better insight in an area of studies that it is still very much fuzzy, that of power relationships in online learning settings. It starts with a short overview of the role of the tutor in facilitating asynchronous online learning. It then introduces two learning design approaches which required different levels of online facilitation. It finally reports the results of the learning design approaches in terms of their impact on the establishment of power relationships between tutor and students and students with fellow students.

The role of the tutor in developing sustainable learning communities

The facilitation or e-moderation of discussions in e-learning had early attention (Berge, 1995). This led within a few years to rather deeper and more informed publications. Guides offering advice to tutors about their online teaching are certainly available (Bender, 2003; Ko and Rossen, 2004; MacDonald, 2006). The literature certainly also offers some generalizations about what is held to constitute desirable approaches to e-moderation that facilitates student-centered learning. These comprise conceptual frameworks and models, as given by Garrison and Anderson (2003).

At the core of a tutor's role in adult learning is the manner in which he or she creates a community feeling among learners by developing social relationships and by intervening in the affective, as well as in the cognitive, domain of the online discussions (Garrison & Anderson, 2003). It was argued that by so doing tutors may better assist students to sustain their work on the learning task (Goodyear, et al., 2001). Rourke, et al. (2001) placed an emphasis on the need for online socialization and community building. They developed a conceptual framework for ‘social presence’ online and argued that a high social presence on the part of the tutor may motivate learners to better engage with the online discussions. Drawing on Rourke, et al.’s model, Stacey (2002) then conducted two studies in a search for effective social presence online. She found that tutors’ social interventions, such as humour, expression of emotions and openness, were acknowledged and welcomed by the students. She also claimed that online social behaviour initiated by the tutor was quickly emulated by many students. With this in mind, Bender (2003: see 88-90) also suggested some strategies for effective online communication on the part of the tutors. Drawing on her experiences as a student and as a teacher online, she focused on some techniques of online communication for the tutors, such as appearing to be listening and caring. In the centre of her online socialization she placed the responsibility to create an online environment where ‘students feel safe to express themselves …and they feel listened to by the tutors’ (89).

MacDonald (2006) argued for a facilitator who works online to ‘engender confidence, and to build a working relationship with individual students’ (24). McConnell (2006) further embraced the need for online facilitation, but he warned that facilitating a networked learning community is hard work. According to McConnell (2006), facilitation requires constant attention to what is going on in the community, and a willingness to make it possible for those participating to "own" the ways in which the community develops. However, he argued that this passing over of the power relationship (from tutor to a community in which the tutor is a member) is full of contradictions. It forces tutors to be open about their educational intentions and to reflect long and hard on their own practice as it becomes manifest in the community. He concluded that there is much still to be understood about what is involved in the process of becoming a facilitator and how this influences the way that students interact. A more specific breakdown of the facilitative options online is given in Vlachopoulos and Cowan (2010a). They analytically distinguish modes of interaction under the colloquial, and somewhat enigmatic, headings of: “one track mind, top of the list, going the second mile, critical friend, balancing priorities and rescuing.” These are explained, amplified and critically compared in their paper. Recently, Laurillard (2012) re-emphasised the importance of having carefully conceptualised roles for teachers supporting learners in different formal learning contexts, including learning through online discussions.

Overall, there is a fair amount of “folk wisdom” available, regarding best practice in facilitation. But there is very little researched evidence to justify the effectiveness of these assertions in the way that learners are learning as part of a community that is ‘free’ to learn. This was the focus of a research project conducted by Vlachopoulos & Cowan (2010b). After analyzing ineffective examples of e-moderation, they introduced the significance of “ring-fencing of facilitative interactions”. They postulated that problems arise for students and their tutors when the facilitative role of a tutor or moderator in learner-centred learning is confused with an educational administrative activity such as planning, arranging, assessing and evaluating student learning. They summed up the need to distinguish between these areas of activity as the desirability of “ring-fencing” facilitation within the area involving learner activity. The paper puts the ‘ring fence’ learning framework to further testing by trying to explore what happens in terms of power dynamics and patterns of interaction between students and tutor when they work within and out of the notional ‘ring-fenced’ arena of learning development.

The context of the study

The author of the paper taught for a full academic year a distance learning postgraduate course offered fully online in a School of Education in New Zealand. The course was designed for people with specific interest in the use of new educational technologies to support the learning and teaching process. It offered a unique blend of theory, research and practice. Seventeen students from a range of backgrounds from early childhood through to tertiary education and to e-learning professionals in the industry took the module. Most of the students were New Zealand based (n=12) with a few others participating from overseas (Malta, India and United Arabic Emirates). The age of the participants ranged between 22 and 40 years old. The module was taught entirely online using a Virtual Learning Environment, a Synchronous Conferencing System and an e-Portfolio System. Students had to participate in a number of online activities in order to successfully complete the module and evidence their learning progress in an e-portfolio. Participation in the online discussions was compulsory and directly assessed following clear assessment criteria which were given to the students at the start of the course. The student had an online induction, which introduced them to the tools and allowed them time to familiarize themselves with both the technical and pedagogical requirements for studying this particular module at a distance.

As part of their online activities students were introduced to the idea of ‘ Guided Thought Discussions’, which was developed as a core activity as part of a fully online MSc in Blended and Online Education at Edinburgh Napier University, in which the tutor was also a guest online lecturer. The main focus of the 'Thought Discussion' is around guided content explorations when students read from a selection of articles prescreened by the tutor and with particular questions raised by the tutor. The tutor's role is to facilitate the discussion and intervene as appropriate to take the discussion further. This activity, although student-centered, cannot be considered student-directed as a number of decisions about the content, the questions and the process has been decided at the outset for the students. For the purposes of this research, this setting was perceived to be operating outside the notional 'ring-fenced' learning area described in the previous section. The students worked for three weeks on such a 'Guided Thought Discussion'.

A second type of online discussion activity was introduced to them two weeks after the 'Guided Thought Discussion'. This time the students selected the articles or other materials they wanted to discuss based on their own personal and professional interests and agreed a set of discussion rules between them, including the key questions to be asked: how often they should be contributing; the length of the messages posted; etc. The role of the tutor in such arrangement was that of a critical friend. The 'Discovery Thought Discussion', which also ran for three weeks, provided a context which for the purpose of this research fits within the notional 'ring-fenced' learning arena, as many of the decisions to be made in working online has to be made by the students themselves.

The important question to ask is whether there were observed differences in both the power dynamics between tutor and students and students and fellow students and if there were differences in the pattern of the interactions between the participants in the two learning designs. This answer, in turn, would help future online facilitators to design appropriate activities that help the creation of a learning community and, most importantly, to be aware of their roles within the communities they aim to set up.

Methods

All online discussion messages from both settings were archived and extracted from the Virtual Learning Environment, in the form of text, after all students had completed their study of the particular module. They were then entered in NVivo 7, a specialized software for qualitative data analysis, and were analysed using a revised version of a coding system developed by the author as part of his doctorate studies following principles of grounded theory. The revised coding system comprised five codes and it is presented in Table 1 below with explicit criteria and indicators from the raw data. The unit of analysis was the whole message. A Kappa reliability check was conducted with one independent coder. A result of agreement of 62% was achieved, which according to Robson (2002), can be considered as satisfactory.

A total number of 311 messages were coded from the first learning activity whereas 334 were coded from the second learning activity. The results from this first part of the analysis provided a useful insight in the intended or unintended purpose of the message posted. It was noticed, for example, that particular students will never initiate a discussion and appear to only be reactive to the tutors' messages. Or that other students will prefer to be proactive but then will never come back to reply to fellow learners' messages or ask follow up questions.

This first part of analysis did not show whether there was any difference in the way that patterns of interaction changed as a result of either a lower e-moderation on the part of the tutor or as a result of the different learning setting. The author revisited, therefore, the data and applied a basic social network analysis (Everret & Borgatti, 1999).The social network perspective suggests that the power of individual actors (e.g a tutor or a learner) is not an individual attribute, but arises from their relations with others. Using the specialized software UCINET the author added all participants (S1 to S17) and the tutor (T1) in a matrix and recorded the interactions between them in the two different settings. For more details about entering data in UCINET see Borgatti et al., (2002). This allowed a closer examination of the group of students and the tutor as a network. Of particular interest to this research were the measures of 'Degree Centrality' and 'Core/Periphery Class Membership'. Degree Centrality is a measure that shows how central a particular actor in a network of people is. Core/Periphery Class Membership seeks to identify a set of actors who have high density of ties among themselves (the core) by sharing many events in common, and another set of actors who have very low density of ties among themselves (the periphery) by having few events in common.

Table 1: The Purpose of Interaction Coding Scheme

Code	Criteria	Indicators
GPI Group Proactive Interactive Message	Student or tutor looks for a response from someone in the group – anyone	Hi all, I've not added messages to this group as I felt you were all having some very interesting discussions without me! Please share your messages/ thoughts with others in the class in the summary section.
GRI Group Reactive Interactive Message	Student or tutor responds to one of the above, or some other message, playing reply back to group	Two rich contributions here, from student 1 and student 2. Thanks for all the work which has gone into these. Student 1writes to a great extent about distance education, which is OK by me.
PI Proactive Interactive Message	Student or tutor looks for a response from a specific contributor, and even asks for it	Student 1 , You said "I also think that information overload can make people… Can you explain a little further for me? Why is it so? Thank you!
RI Reactive Interactive Message	Student or tutor responds to one of the above, or some other message, from and then to a specific contributor	Dear student, thank you for your reply! I am really happy to "communicate" with you here. It was interesting to read your comment….
M Monologue	A new thread. No evidence of interaction with any other participant	The form of E-learning brought me new feeling, which was just like some fresh air! It's really special experience. I tried to control and hide my excitement and made myself involved with the online discussion...

Findings & Discussion

As it can be seen from Table 2, the two most frequent types of postings in relation to the purpose of interaction were the Individual Proactive (PI) and Individual Reactive (RI) Messages with an average number of postings of 7.53 and 4.00 respectively falling into each category. This was not surprising given that the task was set up by the tutor and the majority of the students were asking (proactively) for individual clarifications from the tutor and then were offering replies to the tutor or to particular individuals. They avoided being proactive themselves in terms of motivating each other as a group to take ownership of the activity or by suggesting ways to move on with the discussion or being involved in more than one-to-one interaction with other fellow learners. This was the case despite the fact that the activity itself was clear in the expectations that students should post their own views and also comment on other participants' messages. It is possible that the students felt that it was the tutor's job to prompt further questions and bring the group to together. However, the tutor's presence in this setting was mostly associated with interventions related to assessment and feedback on the process of the activity.

Table 2: The Purpose of Interaction in Activity 1

Participant No	No of GPI	No of GRI	No of PI	No of RI	No of M	Total No of Messages
Student 1	6	4	12	4	3	29
Student 2	3	4	6	3	0	16
Student 3	3	2	9	5	2	21
Student 4	2	1	6	3	1	13
Student 5	2	1	4	2	0	9
Student 6	6	2	9	5	3	25
Student 7	2	2	8	4	2	18
Student 8	3	2	7	3	0	15
Student 9	3	3	8	5	2	21
Student 10	1	4	9	4	1	19
Student 11	1	2	3	4	1	11
Student 12	3	1	7	4	3	18
Student 13	3	4	9	6	2	24
Student 14	1	1	8	4	1	15
Student 15	3	3	7	4	2	19
Student 16	4	3	12	5	3	27
Student 17	0	2	4	3	2	11
Total	46	41	128	68	28	311
Average	2.71	2.41	7.53	4.00	1.65	

The social network analysis results for Activity 1 added extra trustworthiness to the claims made above that the majority of the students were proactively interacting with the tutor and that overall the group appeared to be more on the passive/reactive end of the spectrum of the types of interaction. Of particular importance is the In-Degree value (the number of messages received) for the tutor (T1) in Table 3. The theory of social network analysis would argue that the greater the Out-Degree of an actor in a network, the more influential this actor is. In this case, though, influential appears to be the actor who attracts the most messages, and this is surely T1 with a value of In-Degree of 76. However, it should be noted that T1 also had a comparatively high Out-Degree of 53. It is also worth reporting that the overall Network Centralization values show a higher In-Degree value (Outdegree = 30.147%, versus Indegree = 36.765%). This means that on average, as a community of learners, the students were receiving more messages than they were sending. Many of the approaches to understanding the structure of a network emphasize how dense connections are built-up from simpler dyads and triads to more extended dense clusters such as ‘cliques’. The ‘clique’ analysis in the community of learners in the first activity revealed two major cliques with a strong core and a weak periphery. This means that a small number of students, together with the tutor dominated the discussion, whereas the majority of them were only partially intervening to add to the interactions. It became apparent that in activity one, the students were not interacting as a group of participants who were empowered to take responsibility for their learning, but were mostly working towards satisfying the tutor’s and assessment requests. This has implications for learning design in distance learning, where one of the desired expectations is that students will find their intrinsic motivation to set their own goals and learn as a community of learners from and with each other.

Table 3: Freeman's degree centrality measures for activity 1

		1 OutDegree	2 InDegree	3 NrmOutDeg	4 NrmInDeg
6	S6	12.000	8.000	70.588	47.059
1	S1	10.000	10.000	58.824	58.824
5	S5	10.000	9.000	58.824	52.941
4	S4	10.000	9.000	58.824	52.941
5	S15	9.000	8.000	52.941	47.059
8	S8	9.000	6.000	52.941	35.294
8	T1	9.000	13.000	52.941	76.471
3	S3	8.000	7.000	47.059	41.176
3	S13	8.000	7.000	47.059	41.176
2	S2	7.000	10.000	41.176	58.824
7	S17	7.000	9.000	41.176	52.941
0	S10	6.000	3.000	35.294	17.647
2	S12	6.000	4.000	35.294	23.529
9	S9	6.000	7.000	35.294	41.176
6	S16	6.000	8.000	35.294	47.059
1	S11	6.000	6.000	35.294	35.294
7	S7	3.000	5.000	17.647	29.412
4	S14	2.000	5.000	11.765	29.412

In Activity 2 the students were offered the flexibility by design to arrange their own reading lists, questions, and rules of their discussion. Not surprisingly perhaps the highest number of contributions appeared to be Group Proactive Interactive (mean = 7.43), followed by an almost equal numbers of Group Reactive (mean = 3.12) and Individual Reactive (mean = 3.06) as shown in Table 4. To some extent this proactive attitude to the interactions was the result of the need for the students to move fast as a group to arrange the rules of the discussion in the absence of a high tutor presence. This resulted in a number of replies which were more open to the whole group. These replies were follow up suggestions and prompts for further discussion as opposed to closed answers. Interestingly, this pattern appeared to continue in the main part of the actual discussion activity.

Table 4: The Purpose of Interaction in Activity 2

Participant No	No of GPI	No of GRI	No of PI	No of RI	No of M	Total No of Messages
Student 1	10	7	7	8	4	36
Student 2	7	5	3	1	1	17
Student 3	7	3	2	3	0	15
Student 4	9	2	4	2	1	18
Student 5	9	1	3	1	1	15
Student 6	7	3	4	2	3	19
Student 7	9	3	6	1	1	20
Student 8	6	4	4	3	3	21
Student 9	6	4	4	3	0	17
Student 10	6	3	1	5	1	16
Student 11	7	2	4	2	0	15
Student 12	5	3	6	1	0	15
Student 13	14	2	10	4	1	31
Student 14	8	2	4	2	0	16
Student 15	4	2	10	5	0	21
Student 16	9	4	6	5	1	25
Student 17	5	3	6	4	0	17
Total	128	53	84	52	17	334
	7.53	3.12	4.94	3.06	1.00	

Looking now into the social network analysis data, as presented in Table 5, it can be observed that the occasions in which the tutor (T1) was asked to intervene was significantly lower when compared with Activity 1. This is reflected in the lower In-Degree value of 41.17. The tutors Out-Degree value was pretty much the same as in

Activity 1, but the messages sent were more in relation to the content of the actual discussion and not so much in relation to helping students to sort out the rules of the discussion. This is a very encouraging finding as continuous findings in the area of online distance education show that students without the explicit guidance of a tutor online can lose their motivation to interact or that students can be in a constant need of confirmation by the tutor (De Wever et al., 2010). The overall centralization values of the network in Activity 2 showed a highly balanced communication pattern: Outdegree = 25.735% and Indegree = 25.735%. Finally, it was interesting to notice that in Activity 2 there were nine ‘cliques’ (or small groups) formed , which means that the network appeared to have a strong periphery.

Table 5: Freeman's degree centrality measures for activity 2

		1 OutDegree	2 InDegree	3 NrmOutDeg	4 NrmInDeg
3	S3	12.000	12.000	70.588	70.588

Conclusion

Much use is currently made of virtual learning environment, such as Moodle and Blackboard, to enable “discussion” amongst students. These learners may be in widely separated locations, and so can only interact virtually. There seems to be no agreement amongst tutors and researchers regarding the similarity or otherwise of online discussions with those occurring face-to-face. Most importantly there is little research done into looking how different learning design changes the dynamics of the interactions. A major difficulty when researching interactions, whether between students in groups or between students and a facilitative tutor, is to capture for analysis the fine detail of what was said, or is communicated by written text and especially the pattern of interaction at different times in the online experience. This paper tried to show how a mixed used of methodologies can provide a better overview of what is happening online with students in terms of interactions. More common approaches, like content analysis and coding of messages, can provide a good first understanding of the quality or the depth of the discussion, but methodologies like social network analysis can take us a step further into the domain of networked learning, which in turn provides us with useful information about the extent to which our online learners are working towards a community development or not.

The key message from this study for learning designers and tutors who teach online in fully distance or blended courses is that students who are empowered from the outset through a carefully designed activity that allows them more ‘freedom to learn’ (Rogers, 1969) will find their way of interacting without always needing the strict monitoring of a tutor. This is particularly important if we consider the future of online education to be about flexibility and sustainability of resources, including human resources. . However, it should be noted that in formal learning design enforced participation and authority assessment are usually expected as measures for quality assurance purposes. Therefore, the main exercise of power and authority seems to always take place outwith the ring-fence, even when authority is fully delegated. It became clear that the important thing was not to have a balance of power between the tutor and the students but rather to have a community of empowered learners who are willing to exercise their power to benefit the community After all, if learning is to be truly student -directed there should be a period of learning activity during which the activity, the decisions which matter, the interpretations placed on sourced material and experiences, should be the sole responsibility of the learners, free at that time from pro-active inputs by people who set out to teach, however they define that word, and with whatever benevolent intent.

The research reported here does very little to identify and compare learning outcomes and effectiveness of the learning experience. It only reports findings about the establishment of a community feeling among distance learners. It does not recommend that one type of activity works better than the other in terms of academic performance. In an ongoing course of one year, the researcher could only take snapshots for analysis, and information could not arrange a full and rigorous research enquiry on learning outcomes as a result of the different activities. This is an important limitation which the readers should take into account when interpreting the findings.

Future research will analyse the social network data in terms of the attributes of individual students to explore if there are particular patterns of interactions among students based on attributes such as gender or years of experience.

This paper reports on the outcomes from a preliminary evaluation of technologies and processes intended to support the Assurance of Learning initiative in the business faculty of an Australian university. The study investigated how existing institutional information systems and operational processes could be used to support direct measures of student learning and the attainment of intended learning goals. The levels at which learning outcomes had been attained were extracted from the University Learning Management System (LMS), based on rubric data for three assessments in two units. Spreadsheets were used to link rubric criteria to the learning goals associated with the assessments as identified in a previous curriculum mapping exercise, and to aggregate the outcomes. Recommendations arising from this preliminary study are made to inform a more comprehensive pilot based on this approach, and manage the quality of student learning experiences in the context of existing processes and reporting structures.

Keywords: rubric, assurance of learning, learning analytics, accreditation, TEQSA, AACSB

Introduction

There is an increasing trend for universities to take a holistic approach to managing the quality of educational programs based on objective data and learning analytics (Elias, 2011; Hrabowski, Suess, & Fritz, 2011; Johnson, Smith, Willis, Levine, & Haywood, 2011). Drivers for doing so include ensuring a quality learning experience for students (Curtin University, 2011), and to comply with the reporting requirements of regulatory agencies (TEQSA, 2012) and accrediting bodies (AACSB, 2012). These generally require that students are provided with consistent and equitable learning opportunities that produce the intended learning outcomes, regardless of a student's location or study mode (AACSB, 2007b; Curtin University, 2011).

Curriculum mapping is the process in which generic graduate attributes or program-level learning objectives are mapped to the learning outcomes and assessment in individual subjects (Oliver, Jones, Ferns, & Tucker, 2007; Sumsion & Goodfellow, 2004). This is usually undertaken at the program level to document where students will develop the intended capabilities and skills in conjunction with a given program of study. The Assurance of Learning closes the loop on this design by using objective data to identifying what students have actually learned as a consequence of their participation in the program (AACSB, 2007a). Direct measures of learning can be achieved through standalone testing, or through a course-embedded approach in which regular assessments undertaken in conjunction with formal coursework are used to measure student learning (AACSB, 2007a). Assessment rubrics that are aligned with program-level learning objectives can be used to facilitate the course-embedded approach (Kerby & Romine, 2010). This can be implemented using online tools that are generally available as standard features of a Learning Management System (LMS) (Blackboard, 2012; Cooch, 2012).

Learning analytics available from some LMS providers and third party software suppliers can be used to aggregate and report on course-embedded measurements at the program level. This requires that detailed assessment outcomes for individual students are stored in backend information systems, external web applications, or that these data are retained in the LMS over the duration of the reporting period.

In those cases where LMS data is cleared out in preparation for new teaching periods and assessment data for individual students are not directly available in the University's backend information systems, an alternate approach must be sought to collect and report on program outcomes. This paper reports on the processes and practices for such an approach, and is the principal contribution of this paper.

Context for the pre-pilot study

The business faculty of a large Australian university has established five generic learning goals that can be further expanded into 8 program-level learning objectives. These are discipline knowledge, discipline skills (theoretical principles), critical thinking skills, written communication skills, oral communication skills, collaborative team skills, ethical skills, and socio-cultural skills. Program-level rubrics have been developed that contain descriptors for these objectives at three levels of attainment: below expectations, meets expectations, and exceeds expectations. Generic assessment rubrics have also been developed that expand on the program-level rubrics. These generic assessment rubrics contain criterion descriptors for five attainment levels corresponding to the Fail (F), Pass (P), Credit (CR), Distinction (D), and High Distinction (HD) grade ranges. These are aligned with the program-level rubrics, where the F attainment level corresponds to below expectations, and P and CR map to meets expectations, and D and HD correspond to exceeds expectations.

The intention is to develop unit specific assessment rubrics that are aligned with these generic assessment rubrics for a representative sample of assessments from the Bachelor of Commerce during a subsequent pilot study. This will be used to aggregate and report on outcomes for the program as a whole. This paper reports on a preliminary investigation into the technology and process that will be used in that study, using the Blackboard 9.1 (Service Pack 6) LMS and data extracted from its online rubric tool.

Methodology

Three assessments from two units were selected for participation in this preliminary investigation. These were a spreadsheet modelling assignment from an undergraduate unit called Business Software Tools 200, and a critical essay and a business report from a first year unit called Communication in Business 100.

Business Software Tools 200 is a unit about information systems that support decision-making using spreadsheets and databases. The spreadsheet modelling assignment has criteria associated with the program learning objectives for discipline knowledge, critical thinking and written communication. The discipline knowledge criteria in the assessment rubric involve analysing data and completing two case problems from a textbook. The critical thinking criteria deal with a more advanced and open-ended problem that requires a variety of analysis techniques and considerable interpretation. The written communication criteria cover documentation, referencing and English expression.

The curriculum in Communication in Business 100 has been designed with authentic assessments that examine real business cases. The unit develops communication skills, including critical thinking, persuasive argument development as well as presentation and writing skills. The first assessment is a critical essay in which students examine the social performance of a business and present a critical review in a manner appropriate for academia. The second assessment is a business report. The audience is senior executives of businesses and the writing must be concise and persuasive. These assessments are designed to challenge students to:

- write in ways that are appropriate for different audiences;
- develop arguments that are well supported and use appropriate evidence; and
- demonstrate an understanding of the complex social and ethical issues facing business today.

Unit coordinators for the units to be sampled in this study developed assessment rubrics using the online rubric tool and associated this with their respective assessments in the LMS. The rubrics specified attainment levels for the five grade bands, and had criteria associated with the program-level learning goals. Rubrics were not aligned with the generic assessment rubrics, as the latter were not finalised at the commencement of the semester. A rubric statistics report containing the percentage of students performing at each attainment level was downloaded from the LMS as an MS Excel workbook. Merged cells in the statistics report were unmerged to facilitate copy-and-pasting these into reporting spreadsheets that linked rubric criteria to program-level learning goals, as it was not possible to specify this in the online rubric tool itself.

Two different types of MS Excel workbooks were used in this study. The first workbook type was for recording assessment data. There was one assessment workbook for each assignment in the sample. The workbook contained a tab for data entry. Each criterion and the corresponding percentage of students performing at a given level was copied-and-pasted from the LMS rubric statistics report. These were associated with a program-level learning goal from a drop-down list. Figure 1 shows an example from the spreadsheet modelling assignment.

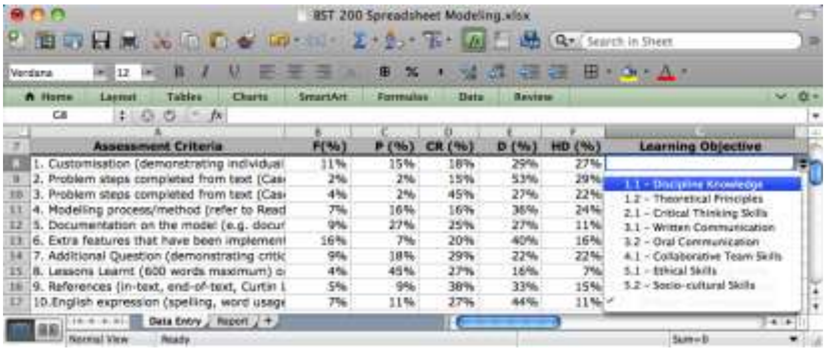

Figure 1: Data entry tab of the assessment workbook for the spreadsheet modelling assignment

A second tab in assessment workbooks automatically tabulated and displayed results for the assessment in text format and as a stacked bar chart. These were presented based on the fraction of students performing at the below, meets, and exceeds expectation levels for the program-level learning outcomes with which rubric criteria were associated.

The second type of workbook was an administration workbook for aggregating results using links to the assessment workbooks. Data was aggregated in tabs associated with each program-level learning objective. A separate tab was used to display aggregated results for all assessments in the sample.

Results

The assessment rubric in the spreadsheet modelling assignment contained three criteria that were linked to the discipline knowledge criterion, four criteria were linked to critical thinking, and three were linked to written communication. Rubrics for the critical essay and business submission assessments each contained two criteria linked to written communication and one criterion linked to critical thinking. Aggregated results for the three assessments are shown in Figure 2. This shows that the majority of students performed at the meets expectation level, except for discipline knowledge in which the majority performed at the above expectations level.

Figure 2: Aggregated sample in the administration workbook for three assessments and two units

There are no results for program-level learning objectives related to discipline skills (theoretical principles), oral communication skills, collaborative team skills, ethical skills, or socio-cultural skills because these assignments did not include rubric criteria and descriptors related to these. For example, although the goal of the written essays in Communication in Business 100 was to undertake a critical review of the social performance of a business, the rubric assessed written communication and critical thinking in developing a sound argument. Criteria for ethical and socio-cultural skills were not included in the rubric and hence these were not assessed.

Discussion

Positive outcomes of using the online rubric and the aggregation results identified were: structured feedback for individual students, an evaluation report showing the percentage of students performing at each criterion and achievement level, and a demonstrable link between assessment criteria and program learning objectives. Challenges identified during this preliminary investigation were limitations of the structure and interface of the online rubric tool in the LMS, writing effective rubrics with concise yet meaningful descriptors, and issues related to workflow using the online tools. This would suggest the need for substantial staff training, up-front technical assistance, and pedagogical support in writing effective rubric descriptors.

Based on observations from this preliminary investigation, it is proposed that individual Unit Coordinators or LMS Administrators with access to the online rubric tool be given responsibility for producing the individual assessment workbooks. This would be done after results are finalised for each assessment.

It is further proposed that Major Coordinators, Heads of Discipline, or an LMS Administrator collect the individual assessment workbooks at the end of each teaching period and maintain the administration workbook that produces the aggregation report. That is, each major such as accounting, management, marketing, and information systems would have its own administration workbook. Such an approach would assist in annual reporting and course reviews, the latter of which are undertaken on a periodic basis. In part, implementing Assurance of Learning at this granularity is manageable in the sense that number of assessments in such a sample would be relatively small. However, it should be noted that the solution described here does not scale well when the number of assessments in the sample set is large. This is because assessment reports must be open for links in the administration workbook to be active.

Longer term, it is reasonable to consider adding a Blackboard building block in which rubric criteria are linked directly to program-level criteria in the online rubric statistical reporting function, alleviating the need to maintain individual assessment workbooks. It is also conceivable that a future enhancement to the Blackboard rubric tool could align rubric criteria to program-level learning objectives using the Blackboard “goals” feature introduced in Blackboard 9.1 (service pack 8).

The approach outlined in this paper will require assignment rubrics to be aligned with the generic assessment rubrics, and to ensure that the sample set includes coverage of each rubric criterion for the set of generic assessment rubrics. This is because different criteria from generic assessment rubrics for a given program-level learning objective might be covered by multiple assessments from different units.

Conclusion

The LMS online rubric tools provides a means to set an assessment rubric, from which meaningful data can easily be extracted. These data give the fraction of students performing at each attainment level for all criteria. From an Assurance of Learning perspective, what is missing is the ability to link criteria to program-level objectives, a means to designate the set of assessments to be included in the measurement, and to aggregate the results. This study has demonstrated that a set of linked spreadsheets managed by staff in accordance with routine reporting processes and practices can be used for this purpose, and will inform a more comprehensive pilot to be conducted in the near future. It is indicated this will lead to a sustainable approach based on objective data from the LMS to ensure that academic programs are of high quality and that the learning outcomes attained by students are consistent with the intended educational design.

Curtin Business School
Curtin University

Tania Broadley
Curtin Business School
Curtin University

This paper reports on a study to evaluate technology-based processes for assessment moderation. The aim was to evaluate standard features found in an institutional Learning Management System, and their compatibility with the values and practices of a large teaching team. The process used an online discussion board forum for tutors, the paring of more experienced tutors with those new to the process, and further meetings conducted in both face-to-face and web conferencing environments. Online rubrics were used for assessing student work and the provision of feedback. A focus group conducted after marking was concluded and the analysis of the discussion board forum demonstrated a strong community of practice with a shared understanding of assessment requirements.

Keywords: discussion board, rubric, assessment, moderation, online community of practice

Introduction

There are many challenges associated with managing quality in higher education. Amongst these are moderating assessments and the provision of feedback to students studying in different locations and modes of study and necessitating the coordination of large teaching teams (ALTC, 2010, 2012; Kuzich, Groves, O'Hara, & Pelliccione, 2010). Drivers include a desire to offer timely and consistent feedback to students in a manner contributing to student learning, and consistent with institutional policy (Curtin University, 2012) and the expectations of regulatory agencies (TEQSA, 2012) and accreditation bodies (AACSB, 2012).

Background

Moderation aims to ensure the consistency of assessment and feedback provided to students (ALTC, 2012). Despite having marking criterion and rubrics that outline assessment expectations, variation in marking is known to be a common issue. In part, this is due to the tacit knowledge that individual markers bring to the assessment process (Bloxham, 2009; Hunter & Docherty, 2011). While controlled studies have shown than marking briefings and training can reduce the variation between markers (Crotwell Timmerman, Strickland, Johnson, & Payne, 2011), there is evidence that this should include group activities and discourse that fosters the emergences of an assessment community of practice (Price, 2005). Such a community would ordinarily rely less on transmitted knowledge, and operate with the goal of developing a shared understanding of assessment expectations.

Research Context

This study evaluates processes that use standard online features of an institutional Learning Management System to moderate assessments outcomes, provide feedback to students, and report on the level to which students have attained intended learning outcomes. This investigation was part of a larger study to evaluate how technology currently in use at the authors' institution could be used to support ongoing assurance of learning initiatives. Work is reported here in the context of using technology that is compatible with the existing values and practices for assessment moderation used in a large first year communication unit. This unit is taught in multiple locations in the business faculty of an Australian university.

The aim of this study was to evaluate the impact of introducing technology into the moderation process with respect to the development of a:

- community of practice amongst the teaching staff associated with a large undergraduate unit;
- shared understanding of marking criterion; and
- consistent approach to the provision of student feedback.

There are typically up to 52 staff and 2,300 students associated with the unit that was the subject of this study during any one study period. It is conducted in multiple face-to-face locations and fully online. Students complete two written assignments and give an oral presentation. All assignments are submitted and marked using a rubric through the assignment manager of the Blackboard 9.1 Learning Management System (LMS).

A range of strategies has been employed to ensure the consistency of marking and the provision of student feedback. Key to this has been encouraging a team approach to marking based on a moderation processes that pairs new and veteran tutors and uses online tools that are embedded in the LMS. The electronic moderation process commences with the posting of a past student paper submitted by the Unit Coordinator to a discussion board forum on the dedicated staff LMS site. This is known as the 'pre-moderation process'. This process commences one week before an assignment is due. All tutors are requested to review the paper that has had all identifying information removed. Tutors are specifically requested to provide feedback that is:

- clear, direct and prescriptive;
- focused on meaningful aspects of the task including content, level of analysis and text structure;
- targeted global feedback that explains the mark relating to the rubric and specific to the task;
- not focused on surface features such as spelling, grammar and referencing conventions; and
- reflects both positive areas of student performance as well as areas needing improvement.

Once the tutor has marked the sample paper and submitted the marked work to the staff-only online discussion forum, they are requested to comment on at least one other tutor's mark and feedback within the forum. At the end of the process, the Unit Coordinator posts a summary on the forum. This summary outlines the key consensus areas, points to consider when marking, and expectations in regards to the quantity and focus of feedback. The pre-moderation process is asynchronous and spans seven days.

The moderation community of practice is further developed in a follow up meeting, conducted in both face-to-face and web conferencing environments. The focus is to discuss outcomes arising from the pre-moderation process and the summary posted by the Unit Coordinator. The goal is to develop consensus and a shared understanding regarding assessment objectives and the manner in which feedback is to be provided.

Upon the conclusion of the pre-moderation process and the commencement of the marking period, tutors are partnered with another tutor. New tutors are paired with a veteran tutor. A veteran tutor is defined as one who has completed all prior training sessions and at least one semester of teaching experience in the unit. Novice tutors may have prior teaching experience, but are new to the unit. During the marking period, tutors are encouraged to send questions or examples to their "moderation buddy" via email or to post these to the discussion board moderation forum.

Upon receipt of students' assignments, tutors are given four days to mark three papers and include student feedback using the online rubric tool, which is a standard feature of the LMS. The Unit Coordinator provides individual feedback to each tutor via email before the remainder of the assessments are marked.

The use of rubrics in this unit is not new. They have been an integral part of the marking process for the past five study periods using an MS Word-based marking form and feedback sheet. Previously, tutors would append an annotated rubric to each student's assignment along with relevant feedback. The level of attainment was indicated by highlighting a descriptor at a given attainment level in a specified colour, and providing feedback by copy-and-pasting from a bank of common feedback statements.

Commencing in Semester 1, 2012, marking and the provision of student feedback was conducted entirely online using the LMS rubric tool. Tutors indicated the level of attainment by clicking in the appropriate cell of the online rubric. Marks were not directly computed based on this, so as to focus student attention on feedback rather than the mark awarded for individual rubric criterion. Instead, the tutors awarded one mark for the assignment as a whole. Global feedback was provided to justify the overall mark via text or via an attached audio file. Additional feedback could also be supplied in a text box at the level of individual rubric criterion and level descriptors.

In previous study periods, the pre-moderation process required tutors to email marked samples as part of the pre-moderation process, rather than using the discussion board. Tutors would utilise email to communicate or attend 'round table' discussion meetings open to anyone who wished to discuss marking concerns. These were not compulsory meetings but rather took place in an organised venue for tutors to meet during the marking period.

Reporting on the affordances and limitations of using an online discussion board to share tacit knowledge during the pre-moderation process, and the extent to which the online rubric tool is consistent with established marking and moderation workflows are the principal contributions reported in this paper.

Methodology

The study adopted a triangulation mixed methods design to "simultaneously collect both qualitative and quantitative data, merge the data, and use the results to understand the research problem" (Creswell & Plano Clark, 2007). Tutors participated in a focus group where semi-structured questions were asked. The research questions were designed to elicit the challenges and benefits that tutors experienced in terms of making the transition from a marking rubric implemented in an MS Word document to using the online rubric tool. Additionally, the challenges of interpreting learning goal statements and level descriptors were investigated. Tutors were asked to reflect on the impact of using technology on the student and academic workflow and on the quality of feedback provided to students. An articulation of the interviewees' reflections on their experience was made as complete as possible by following up with probing questions (Fraenkel & Wallen, 2006). Focus group data were transcribed and analysed using NVivo software.

Learning analytics is defined as "the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs" (SoLAR, 2011). Analyses of quantitative data included the application of SNAPP, a learning analytics tool that visualises the network of interactions resulting from LMS discussion forums. Tutor posts from pre-moderation discussions related to an assignment (n=47) from the staff-only LMS site were used to explore data interrelationships. Visual representations were developed in order to ascertain the nodal connections between tutors. The names used in these visualisations and quotes in the analysis of discussion board posts have been randomised to protect the identity of participants.

Additionally, student data for the first written assignment (n=1027) were extracted from the LMS and the distribution of attainment levels were evaluated.

This research was approved by the Human Research Ethics Committee at the authors' institution.

Results

There were 41 tutors involved in this unit during the study period reported in this study. Of these 34% (n=14) were men, and 66% (n=27) were women. All of the tutors taught in the blended delivery mode, except 1 tutor who taught in a fully online delivery mode. There were 24 tutors (59%) who posted in the tutor-only pre-moderation discussion board forum. Of those participating in pre-moderation exercise, 100% (n=24) posted a mark and feedback on the sample student paper, and 78% (n=18) offered feedback on the marked sample posted by at least one of their peers. There were 46% (n=19) members of the tutor community who participated in the focus group, held during an end-of-semester debriefing meeting.

Results arising from the analysis of the pre-moderation discussion board form and the focus group are given below, along with the levels of attainment distribution for the assignment.

Pre-moderation in the Online Discussion Board

The pre-moderation discussion board pattern of participation and interaction pattern for assignment 1 is shown in Figure 1. Each red square represents a tutor, and each arrow represents a discussion board post in response to another member of the teaching team.

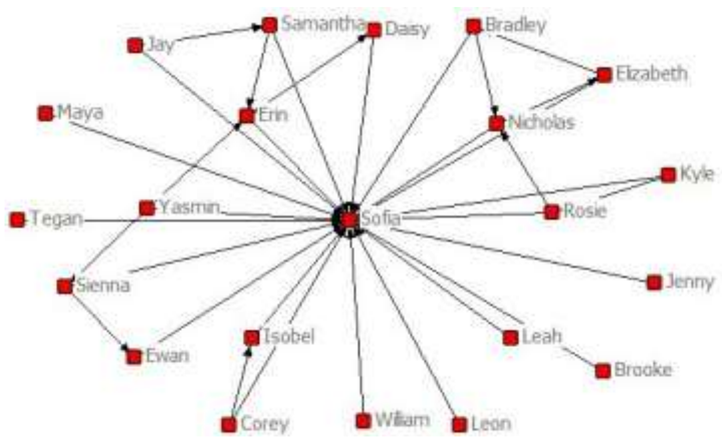

Figure 1: Pre-moderation discussion board participation and interaction.

Most of the posts contained reviews in which tutors applied the marking rubric to the sample paper posted by Sofia, the Unit Coordinator, as part of the pre-moderation exercise. Other posts fell into one of several categories described below.

Confirmation of findings and areas of agreement

In responding to Erin's review and feedback, Daisy wrote, "I like Erin's approach to this feedback. Her comments are positive and helpful. Erin also commented on the student's strength's and weaknesses and recommended places where the student can find further help in academic writing." Yasmin agreed, supplying a bit more detail in her response to Erin: "I like the way you have structured your feedback. You have identified a number of positive points in the first paragraph that would encourage the scholar to take overall feedback into account for the next assignments."

Suggestions for improving student feedback

Corey reported that he found many of the same issues identified by Isobel in her review, but offered suggestions on ways she could improve her review. He posted, "I picked up a lot of the same things you did with this example. The student obviously faced issues with the mechanics and execution of language, which unfortunately interfered with their argument construction and clarity. I did appreciate the fact that they had put some effort toward the structure though. My feedback for your example would be to try and find some positive aspects to comment on the written feedback section, and put them first. Hopefully students will have something positive to take away from their efforts, and a good set of feedback from which to receive further coaching". It is interesting to note that Corey is modelling the advice given to Isobel in his post to her. That is, he starts his post by offering positive feedback before offering suggestions regarding how she could improve her feedback.

Points of disagreement and ensuing discussion

Ewan, a veteran tutor, posted "I have attached the marked sample. I will comment on Sienna's when it appears as she wanted to be my moderation buddy." Interestingly, while Sienna responded to Ewan, he never responded to her assessment of the sample assignment. In part, this was because the novice tutor had disagreed with Ewan, who was the veteran tutor which whom she was paired. Although she starts her post by identifying points of agreement with Ewan, she continues, " Not having time to proof read is no excuse and I feel the referral to the Comm[unication] Skills Centre is necessary. I'm not sure I agree with the high mark you have given this scholar. I feel this level of academic writing and lack of research in the reference list is not worthy of a credit pass." Because Siena disagreed with Ewan, they chose to continue their communication privately via email instead of the more public discussion forum. Sofia, the Unit Coordinator, eventually intervened and moderated a broader discussion on the points being discussed by this veteran/novice pair at the next tutor meeting. Ewan, the veteran tutor, changed his view following the moderated synchronous meeting with his peers. These meetings are held face-to-face and simultaneously via web conferencing for the benefit of remote staff.

Aligning assessment feedback with the rubric

Several posts emphasised the importance of linking feedback to the marking rubric. For example, Brook posted the following in response to Jenny: " I like how the overall feedback is given in a positive attitude. It would even be more helpful for the scholar if he/she was given insights on why he/she had 'pass' on the first two columns [of the marking rubric], which would increase her understandings on the unit and he/she would be able to carry this forward to the second assignment."

Communication outside of the discussion board
There were instances in which posts referred to communication taking place amongst tutors outside of the discussion board. For example, Yasmin posted the following in response to Erin: “As we discussed earlier on Facebook, our marking is quite similar…” Similarly, an obvious absence of posts was due to communication that shifted to email, or that was brought to the subsequent tutor meeting conducted face-to-face and via web conferencing. The later became evident following Sienna’s post outlining her disagreement with Ewan’s assessment that was noted previously.

The importance of making student referrals to the Faculty’s Communication Skills Centre
In response to cases where a tutor focused their review on correcting grammar, sentence structure, and referencing, some posts suggested that a better approach would be to refer students to the Faculty organisation responsible for assisting students in improving their written and oral communication skills. For example, Rosie posted the following in response to Corey’s review: “Correction of the grammar issues in the introduction seems generous given the volume of marking when we go ‘live’. I’m not sure if it will improve the student’s future performance in academic writing. It is more likely that intervention by the Communication Skills Centre as Corey recommends will improve the student’s English skills.” Similarly, Brooke posted the following in response to Jenny’s review: “Given the level of urgency (the scholar scores a ‘fail’ on language and convention), it would be better to strongly emphasise the necessity to look for assistance.”

Feedback and Levels of Attainment

Figure 2 shows a sample of the feedback provided to students using the online rubric tool and the descriptors associated with each range. The level of attainment for each assessment criteria is indicated, along with the associated descriptor. In this instance, the tutor has provided feedback to the student to justify the level awarded for each criterion, along with global feedback. Positive aspects of the assessment are indicated, along with suggestions for improvement.

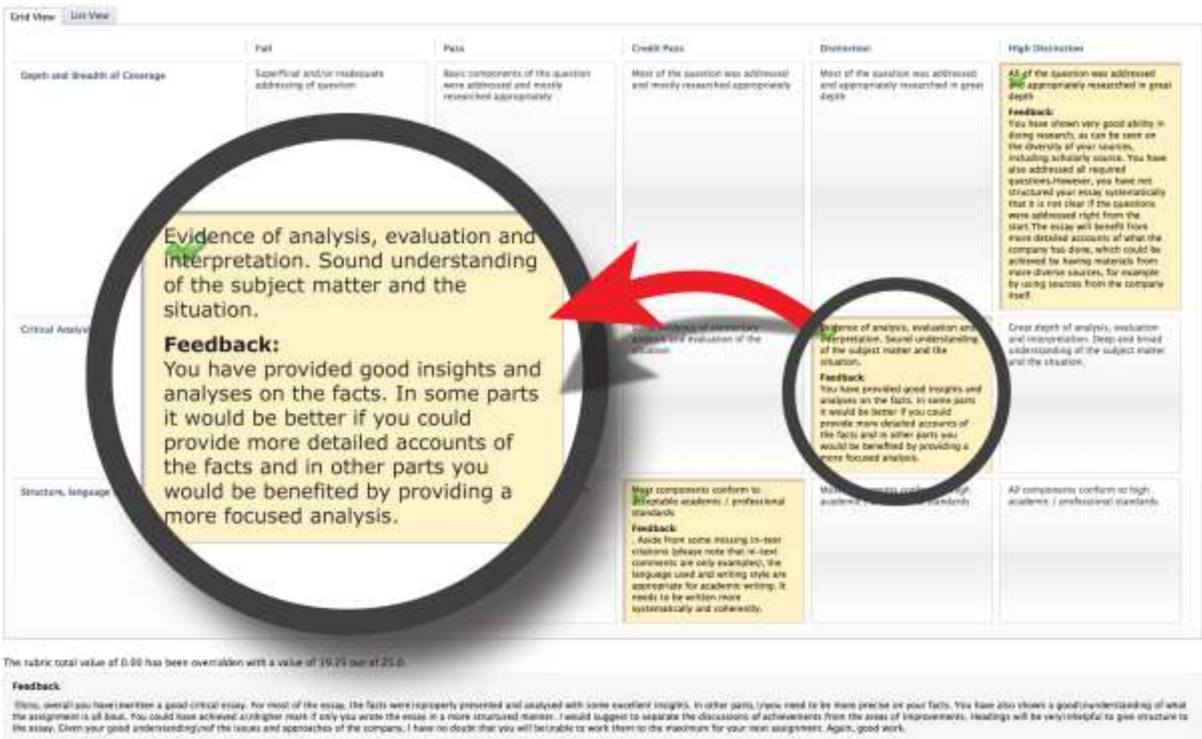

Figure 2: Feedback associated with each level of attainment in addition to global feedback

Levels of attainment for the entire cohort following moderation are shown in Table 1. The table shows the distribution across Fail (F), Pass (P), Credit (CR), Distinction (D), and High Distinction (HD) grade ranges. Within the Faculty of Business at the authors’ institution, Fail is an unsatisfactory level of attainment, whereas Pass and Credit levels denote that a student has met the stated learning objectives, and Distinction and High Distinction levels denote that they have exceeded these expectations.

Table 1: Percentage of students performing at each level of attainment

Rubric Criteria	Levels of Attainment				
	F	P	CR	D	HD
Depth and breadth of coverage	10%	26%	33%	22%	9%
Critical analysis	11%	25%	37%	22%	5%
Structure, language, conventions	13%	24%	36%	21%	6%

The rubric was used as a framework for providing student feedback. In this instance, the rubric was not used to directly compute the overall mark awarded. However, the observed distribution for the levels of attainment is generally consistent with expectations, with the majority of student falling into the pass and credit bands.

Analysis of the Tutor Moderation Focus Group Data

Following the completion of marking, a formal focus group was held as a debriefing activity in conjunction with a regularly scheduled tutor meeting. Common themes identified related to the nature of multiple pathways for tutor-tutor interaction and the varied mechanism used by the tutor community to interact. The type of information tutors exchanged related not only to provision of rubric-focused feedback, but also included information about successful workflows given the idiosyncrasies of the online technologies being introduced for marking and the provision of feedback.

Multiple Pathways for Tutor-Tutor Interaction and Information Exchange
A variety of formal and informal communication pathways were available to the tutor community, including the tutor-only discussion board, veteran/novice moderation partner pairings, and moderated discussions during formal meeting. Together, these provided multiple opportunities for peer interaction and the flow of information between tutors. The collegiate and routine manner in which tutors shared information through these many channels was a common theme that emerged from the focus group. For example, commenting on information exchange between members of the teaching team, Sofia stated: "[the community shared information] through the tutors, hats off to them. They were talking to each other and letting each other know, I've learnt this in conversations. And when people would raise questions I'd be learning too, so I would be, 'I'll try this. I've just learned this.' So imparting that information on an individual basis."

Interestingly, there was evidence that the flow of information between paired veteran/novice moderation partners flowed in both directions. That is, veteran tutors learning from their more junior counterparts and other members of the tutor community. For example, during the focus group, one novice tutor said, "I learned a lot from her" in reference to the veteran counterpart with whom she was paired. The veteran tutor responded by saying, "I learned more from you." Other examples of veteran tutors learning from other members of the community or adapting their viewpoint were also identified elsewhere in this study. Recall the experience of Ewan and Sienna in their disagreement regarding the mark they awarded the sample paper during the pre-moderation exercise. As has been noted, Ewan, the veteran tutor, changed his view to that of Sienna, the novice tutor, following a discussion with theirs peers that was moderated by the Unit Coordinator during a formal tutor meeting.

In some cases, it was reported that the interaction between veteran/novice moderation partners extended beyond email, discussion boards, and formal meetings. During the focus group, for example one participant said "Jenny and I are marking buddies, so we made it a habit to meet on each assignment, just take one day and discuss everything."

However, some tutors reported working alone, but later coming together to share information at the formal meetings, held face-to-face and simultaneously through web conferencing. For example, one tutor said: "Yeah, we had that first meeting and then after that it was very much off you go. We have another meeting after you met [the first time]. We caught up but we all were learning on the job like, for instance, put your grading first [before entering feedback in the LMS rubric tool]. None of us knew that. So a lot of it was learning on the job, me included."

For some tutors, the pre-moderation process conducted in the discussion board was an important exercise. It illustrated the potential for marking variation in the absence of a shared understanding regarding the meaning of marking descriptors, and fostered dialog amongst tutors that informed their marking. For example, during the focus group, one tutor reported that "… we put the paper up and then everyone can look at the paper and mark it to give some feedback. And there were some wide ranging marks for some of those papers. And there was quite a lot of discussion before we actually starting marking."

The provision of rubric-focused feedback

In general, tutors in the focus group reported being comfortable interpreting assessment rubric descriptors. In part, this may be because rubrics have been used in this unit for the past five teaching periods, but also because they were the focus of discussion using the various formal and informal communication pathways available to the tutor community. One tutors said, "I found the descriptors fine. I mean, they're really basically an outline between the five distinctions between terrible and brilliant and you interpret it how you interpret it, I guess. And we didn't have any problems. I guess we have similar thoughts on what the descriptors [mean]…"

Focus group comments like these reflect, in part, that the online rubric tool was configured to support the provision of feedback against levels of achievement for individual assessment criterion, rather than as a means for calculating and allocating a mark. That is, tutors were instructed to provide feedback based on each rubric criterion and associated level descriptors, but the final mark was not directly computed on the basis of this. In part, this was an intentional part of the assessment design. The aim was to focus student attention on the feedback they received, rather than on the number of marks awarded for attainment of each criterion at a given level. One tutor described a process in which he referred to the descriptors rather than the titles for the corresponding level of attainment, the latter of which better reflect the nomenclature associated with a mark band (e.g. Fail, Pass, Credit, Distinction High Distinction). He said, "I went to the grade related descriptor and checked to see if the paper satisfied that, within those parameters…. I probably kept that more in my head than the titles that were on the rubric."

"My biggest problem," said one tutor, "it's got nothing to do with the rubric… [My biggest problem] is working out the workflow. That's taken me a couple of hours to fathom out which is the best process for me." The rubric tool, for example, prescribed a particular workflow that some found to be problematic. "The problems that I had for quite a few days was I didn't want to put the grade in," said on tutor. "I wanted to put the [feedback] comments in but it wouldn't save my comments until I'd put my grade in because my comments were always going to stay. My grade, I just wanted to mark a few first before, to give myself an idea of where they were on a scale. And the rubric wouldn't allow me to do that. I spent absolutely hours trying to work out what I was doing wrong. I thought I was totally incompetent." Later, following consultation with a senior tutor, he learned that there was a prescribed order to the operations he was trying to perform.

Some tutors described how the online rubric tool assisted them in providing feedback that was aligned with the rubric descriptors. For example, one tutor said, "I'd always click on 'show description' and 'show our feedback," so viewed it in a way that I could see my feedback as I was entering it in. And I guess, for me, as a first marker, it was structuring my feedback into those three criterias [sic]."

Although the assessment rubric was intended to guide the provision of feedback rather than the calculation of an overall mark, it was clear that at least some tutors used it for the later. For example, one tutor said: "… I used three [rubric criterion] sections independently and gave feedback on three sections independently. So I marked them all at 33.3 effectively. So if they were a distinction in this area I had a comment on why, so it did relate to that content on the rubric. And the same with the middle component and the same with the language structure, so some I might have had a fail with the language but a pass in the other two areas or some were even a credit, pass, distinction. But it averaged out to their grade, so I didn't find that a problem at all because I marked the independent sections." One participant expressed concern that if the assessment rubric had been used for calculating the mark rather than guiding the provision of feedback alone that it may have skewed the results distribution. He said: "I think if we just marked basically, responded to those descriptors, we wouldn't have given out very many high distinctions. Because it talks about … I can't even remember the words but they're words that preclude much of the material that was submitted. But we'd have to interpret that material in the context of where these students are at and within their cohort. So exceptional or exceeds academic standards, or whatever the words are…"

Workflow and technology issues

A significant portion of the focus group discussion centred on issues related to how technology impacted workflow and the provision of feedback. Issues included the order of operations and the time taken to provide feedback using the online rubric tool, and the process for providing audio feedback for tutors who chose to supply their feedback in that format.

There was disagreement amongst the tutors regarding the length of time that it took to mark. "So basically we are given 15 minutes to do a marking and this clearly exceeds 15 minutes," said one tutor. While some agreed, others did not. While individual tutor competence with information technology-based tools may be a factor in this, workflow was also seen to impact the time it took to mark each assessment. One tutor said, "…I found that I was creating my own bank of [feedback] comments and that sometimes I'd pull them together, this bit from there and that bit from there." This was reminiscent of an approach that had been taken during previous teaching periods when an MS Word version of the rubric was used in conjunction with a bank of common feedback statements that could be cut-and-pasted into the correct place on the rubric feedback sheet that was returned to students. The Unit Coordinator commented that the unit had moved away from using a centralized bank of tutor feedback statements, as it had grown too large to be practical, was too impersonal, and not in the tutor's own voice or style. "So that big bank of comments that we've previously had in the previous version didn't always suit the tutors, " she said. "Because some would look at it and just go, 'I can't make that comment. It's obviously not from me. This is from a middle aged woman making a comment, or a middle aged guy'."

All tutors supplied students with global feedback, guided by the level of attainment they had selected for each assessment criterion in the online rubric. Some tutors also provided feedback at the detail of each rubric cell to further justify why the assessment was deemed to demonstrate performance at particular level. This difference in workflow may have contributed to variation in the time to mark an assignment in some cases. "… I think there's a bit of a misunderstanding. You don't have to give comments on every box in the rubric, as far as I understand," said one tutor. She continued saying, "One global comment is fine in the selection of the areas. So it's actually a time saver because you don't need to copy and paste the rubric and then go to Word and click the different colour to highlight it [as was done when we used the MS Word rubric in the past]. You just click three times…"

Discussion

The educational design of the unit in this study involved engaging students through a variety of communication channels and activities that use technologies like Facebook, Twitter, Hotseat and Voicethread. These were used alongside more traditional forms of communication and engagement that included classroom-based discussions and group presentations. As described in the Unit Outline, co-curricular participation in the activities of the student Debate Society encouraged to assist students to further develop their communication skills. To a great extent, providing students with multiple learning experiences and modes of engagement was an intentional part of the educational design of the unit. This approach was based on research that shows that students tend to gravitate to different kinds of learning resources and experiences based on individual learning styles and preferences (Allert, 2004). It was also based on the philosophy that it is best to provide a range of these to suit the needs of a diverse cohort (von Konsky, Ivins, & Gribble, 2009). This same philosophy has transcended the boundaries between student and learning facilitator, leading to a range of communication and interaction strategies designed to engage a diverse tutor community while fostering a team approach to marking and assessment.

Just as students gravitate towards those activities that match their individual learning styles, preferences, and perceived learning needs, so to did members of the tutor community. For example, the focus group demonstrated that some veteran tutors had the capacity and ongoing desire to improve their skills and learn from other members of the community, including from their more junior peers. In contrast, other veteran tutors demonstrated a "know-it" attitude, and felt less inclined to participate in community exercises having participated in similar activities during prior semesters. Encouraging these veteran tutors to remain active participants in ongoing tutor community activities remains a challenge in some cases.

Additionally, tutors generally possess a variety of attitudes regarding the use of technology (Dooly, 2009; Kessler, 2007). This can be due to a variety of factors including gender, confidence (Guichon & Hauck, 2011) and the amount of time a tutor has been working in the role. The extent to which a tutor's level of information technology competence impacts participation in the pre-moderation discussion board activity is unclear, and represents an opportunity for further research. Interestingly, the tutor responsible for the fully online implementation of the unit discussed in this study did not participate in the pre-moderation discussion board forum.

Whilst a strong collegial team exits, an element of resistance to the introduction of the new technology was evident in the present study. New tutors generally accepted that the technology was required to complete their role. At the onset of the present semester, however, the Unit Coordinator noted that some veteran tutors expressed a preference for continuing to use the old MS Word-based assessment rubric. The intention was to address this by emphasising the benefits of using the new tool during a training workshop. Indeed, Despont-Gros, Mueller and Lovis (2005) suggest that acceptance of change and the successful use a new information system is better achieved if it is perceived to have a positive impact upon an individual's work. Consequently, the training workshop emphasised how the new technology was to be employed on an operational basis and with respect to the management of workload. This included a presentation on the online rubric tool and a live demonstration provided by a University expert. The relevance of the online rubric tool was also discussed in the larger context of the business faculty's Assurance of Learning initiative.

Despite this training, the workflow employed by individual tutors and the impact of the rubric tool on marking time was seen to vary. To some extent, this may be because the online rubric tool was not used in conjunction with the pre-moderation exercise. Instead, tutors appended a marked up MS Word version of the rubric to the sample of prior student work, as was the practice in prior semesters. This placed the emphasis on the feedback tutors provided on the past student paper in the exercise and was easy to implement in the context of the discussion board. However, this did not provide hands-on exposure to the new online rubric tool, or an opportunity for tutors to discuss the workflow associated with the new technology based on personal experience prior to the commencement of marking.

That is not to say that implementing the pre-moderation exercise in the discussion board was unsuccessful. The new version retained the original activity in which tutors practiced marking and providing feedback on the prior student paper. In previous semesters, tutors sent their assessment and feedback on the paper to the Unit Coordinator. She later summarised the feedback of the entire tutor team before they began marking. In this sense, the discussion board version of the pre-moderation exercise was consistent with the values and practices of previous semesters. However, in the original version of the exercise there were no structured opportunities for tutors to interact or discuss the exercise as a community. Implementing the activity within the discussion board extended the exercise to one that fostered interaction and discussion amongst the tutor community. Individual tutors still provided a mark and feedback on the prior student paper, but were effectively given the responsibility of analysing the contributions of their peers for the benefit of the entire community, which was originally a responsibility solely vested in the Unit Coordinator.

Participation rates in the new version of the exercise were very encouraging, with 78% of those posting their assessment and feedback on the past student paper also commenting on at least one post made by a peer. While not all tutors posted within the forum, the extent to which lurkers may have benefited from reading the posts of their peers is not clear, nor is the extent to which this may have informed the offline dialog amongst veteran/novice moderation pairs. This highlights the need for periodic synchronous meetings, whether they occur face-to-face or via web conferencing, as an opportunity to consolidate community views and share the interactions that have taken place both within and outside the discussion board forum. Increasing participation rates amongst all members of the community will remain a goal of the exercise, as it is adapted in future semesters.

Moreover, implementing a robust moderation process has been a goal of this unit, with the aim to provide students with more consistent, timely, reliable and relevant feedback. There is anecdotal evidence to suggest that this has led to a significant reduction in appeals and discussion amongst students about mark variation, and represents an opportunity for further research. The collection of meaningful analytics that demonstrate the effectiveness of the evolving moderation process and the quality of its outcomes will remain also an important consideration as the moderation process evolves. This is not only because of the teaching and learning implications, but also to demonstrate compliance with university policies (Curtin University, 2011) and the expectations of regulatory agencies (TEQSA, 2012) and accrediting bodies (AACSB, 2012).

Conclusions

The use of assessment rubrics has the potential to reduce the time taken to mark assignments while providing more consistent feedback to students. However, the present study has illustrated the importance of establishing efficient workflows based on the experience and shared expertise of the tutor community, particularly when it involves the introduction of new technologies like the online assessment rubric.

Moreover, the research presented in this paper corroborates prior work demonstrates the value of marking briefings and tutor training (Crotwell Timmerman, et al., 2011), and of group activities and discourse that fosters the emergence of a moderation community of practice (Price, 2005).

This paper has described a moderation community of practice that provides members of the community multiple opportunities for interaction and engagement. The goal has been to foster a community of practice in which all members of the community take responsibility for the consistency and quality of the feedback provided to students. This reflects the evolution of moderation processes in a unit where there has been a culture of open communication amongst the tutor community for several semesters.

The establishment of the pre-moderation discussion forum was seen as an extension of this culture. It was not the intention to extinguish tutor interaction through other communication paths, nor has it. The data suggest that tutors engage with the established processes and interaction opportunities to varying degrees. Formalising participation expectations, establishing mechanisms to share tacit knowledge and managing offline communication within the wider tutor community will remain an ongoing challenge for the Unit Coordinator.

The pre-moderation discussion board forum was designed to complement existing moderation strategies and provide a range of opportunities to meet the needs of a diverse tutor community. The analysis of the discussion board forum and of the focus group held during the end of semester debriefing has provided data that will inform future iterations of these processes as the moderation community of practice described in this paper continues to evolve in future semesters.

Twitter Learning Analytics in R

Lyndon Walker
Swinburne University of Technology

There is presently no literature about the application of learning analytics to student learning activities that use Twitter beyond those describing the Twitter activities themselves and/or student survey feedback about these activities. This paper seeks to address this gap by examining the application of some data visualisation analytics to student activities on Twitter using the R statistics software programme. For those who already use Twitter as a teaching tool it illustrates some useful methods for analysing learner data in order to more effectively use Twitter in their teaching. For those who do not use Twitter in their teaching, they will hopefully still find the descriptions of various ways that Twitter is currently used, and the application of learning analytics informative for their teaching practice.

Keywords: Learning analytics, data visualisation, statistical software,

Introduction

Twitter is increasingly being used as a tool for student engagement and interaction in tertiary education (Lowe & Laffey, 2011). However, the analysis of the use of Twitter in academic literature to date has been based around either student surveys and/or the reflections of the teacher. This paper contributes to the conference theme of “leading in a climate of change”, extending the existing research by illustrating some learning analytics techniques that can be applied to Twitter data in order to examine student’s patterns of usage and interaction.

The goals of the paper are twofold. The first is to describe some of the ways in which Twitter is being used in tertiary education. The second is to encourage the use of learning analytics to enhance this teaching by providing examples of using Twitter-based data. In particular, this paper focusses on using the R statistical software programme (www.r-project.org), and showing how it can be used to extract and work with Twitter learning data. R is an open-source, free to download, statistical software tool. It has a wide user base, particularly in academia, and is well supported by email and web groups.

Learning Analytics

Learning analytics, which is also known as academic analytics, is the application of statistical analysis to learning data. Baepler and Murdoch (2010) describe it as the business intelligence tools to teaching and academia, with the goal of enhancing student outcomes. The state that, “academic analytics combines select institutional data, statistical analysis, and predictive modeling to create intelligence upon which students, instructors, or administrators can change academic behaviour”. Learning analytics involves the use of objective quantitative data rather than just quantitative measures of student surveys (Phillips et.al., 2011) and provides richer data that can be analysed to help inform instructor practice. Dawson, McWilliam and Tan (2008) highlight the importance of academic analytics, especially the ability to take data that is generated by learning activities, analyse it, interpret and then translate the findings into practice. This paper will focus on using several visualisation tools from R to examine some of the data generated by students using Twitter. This data visualisation will be the precursor to quantitative analysis to be completed in future research.

Twitter as a Teaching Tool

Twitter is used in a number of different ways in teaching. These include information transmission (student and/or teacher), collaboration and discussion (both in-class and outside of class), and micro-blogging. Kassens-Noor (2012) showed how Twitter can be used in and out of class, providing instant feedback in lectures, as well as being used as a discussion and collaboration tool. Twitter’s asynchronous nature allowed Saeed and Sinnappan (2011) to have students micro-blogging, and interacting across time and space in an e-commerce course. Rinaldo, Tapp and Laverie (2011) describe how to use Twitter as a pedagogical tool in a marketing course to engage students in class activites, and also to demonstrate to the students how social media are used in that discipline.

Cochrane (2010) showed how web 2.0 tools, including Twitter, could “facilitate learning experiences that bridge time and distance” and allowed students to collaborate internationally. Cochrane describes how Twitter was used to facilitate communication between students and lecturers in New Zealand and Ireland. Crews and Stitt-Gohdes (2012) describe how twitter was used as part of a business communication course. They had students use Twitter as a business communication tool, tweeting messages in order to promote a non-profit organization. Twitter can also be used in a large lecture theatre situation to create dialogue between individuals, and to increase student engagement (Tyma, 2011).

In each of these examples, the use of Twitter is described, and is generally supplemented by the reflections of the academic, and in some cases, student feedback or surveys. However, learning analytics could provide additional information to help direct efforts and use Twitter more effectively in teaching.

Tools for Analysing Twitter in R

The R software provides the ability to download Twitter related data, and to be able to plot and analyse it. One of the more useful downloadable packages is *twitteR* (http://cran.r-project.org/web/packages/twitteR/index.html). This package allows users to extract information on followers, those following, posts, hash tags, etc. It can be integrated with other packages to allow for data visualisation and analysis. The three areas where analytics could help to investigate student usage of Twitter are: examining the frequency of use, mapping users and their social networks, and examining the content of student tweets.

Frequency and intensity of use

The simplest analysis of Twitter is to examine when, and how often students are posting. Rinaldo *et.al*. (2011) comment on the positive impact that Twitter has had on their teaching but lament the fact that it is difficult to monitor usage, particularly for a large class, and that this is problematic if they wish to include Twitter contributions as a summative component of their course. However, the usage information required to track and grade students can be accessed using the twitteR package, and much of the tracking and analysis could then be automated.

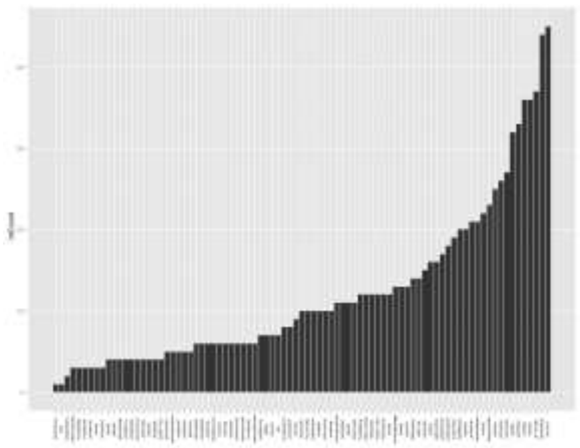

Figure 1: Tweet counts by user (from http://www.r-bloggers.com/a-quick-view-over-a-mashe-google-spreadsheet-twitter-archive-of-ukgc12-tweets/).

Figure 1 shows a sorted bar graph of the number of tweets for a selection of users. In this example, the tweets were saved to a Google spreadsheet for archival purposes, then loaded into R and plotted. However, the *searchTwitter* function in the *twitteR* package also allows for the retrieval of tweets. This could be used as a grading tool, or to inform future activities in Twitter.

Mapping relationships and social networks

Kassens-Noor (2012) and Saeed and Sinnappan (2011) talk about using Twitter to create collaborative communities, and to foster collaboration between students. However, in each case little was done to examine whether this was occurring. Figure 2 shows a map of Twitter followers (left) produced using the *twitterMap* function (http://biostat.jhsph.edu/~jleek/code/twitterMap.R) and a social network diagram (right). For online education, the ability to track student locations on a world map can be useful for tracking where your students are working from, which in turn can be useful for organising interactions and collaborative work, such as the activities described by Cochrane (2010).

Figure 2: Map of Twitter followers (left) and social network graph (right)

Student interactions can be examined in more detail by looking at how students are interacting with one another using social network analysis and social network graphs. Dekker (2011) describes the social network analysis of discourse, where interactions between individuals are graphed and modelled. By mapping the connections between students we can examine relationships and get a more detailed picture of interactions between participants (and identify non-participants). Figure 2 also shows a social network map, with the points representing students, and the lines representing the connections between them. In this example we can see that all of the students are interconnected, but with this kind of analysis we can identify students who have disengaged from Twitter based activities. This graph was produced using the *sna* (social network analysis) package in R.

Hashtags, word clouds and sentiment

One further level of advancement in the analysis of tweets is to examine the content of the tweets themselves. Bollen, Mao and Pepe (2009) describe how text-mining can be used to extract mood and sentiment information from tweets over a period of time. These can be graphed in terms of positive or negative, but also examined by translating key words into a word cloud, where the size of the word represents how often it occurs.

Figure 3: Word cloud

Figure 3 shows a word cloud, produced using the *tm* (text mining) and *wordcloud* packages. It allows for a quick visual analysis of keywords that are being used. Using the *twitteR* package, tweets can be searched and organised, and examined by keywords, hash tags or other patterns. This can give an instructor an idea of the key themes that are running through student Tweets, and help inform future teaching, and can be shown to students to help them seem the patterns in their collective tweets. The student activities presented by Crews and Stitt-Gohdes (2012), where students are promoting a non-profit organisation, could be collaged and used in future classes, where students could examine patterns and themes in their tweets.

Conclusions and Future Research

This paper has described some examples of how Twitter is used in tertiary education, and how the R statistical software could be used to analyse Twitter information generated in some of these teaching activities. Although R is not the only analytics tool that can be used to analyse Twitter usage, patterns and networks, it is free, open-source, and has a well-supported user community. The analysis packages are flexible and integrate with easily with one another. This makes it a good choice for those looking to start working with learning analytics.

For those who already use Twitter in their teaching, learning analytics can improve the practice of current Twitter activities in higher education by allowing users to examine patterns in student usage, student interaction, and message content. Beyond this, one of the appealing future possibilities is to make the teaching/learning/analysing process with Twitter more circular, where learning analytics will not only inform the teacher but also the learner. Students can be provided with analysis and output of the analytics during the course, allowing them to reflect on Twitter their use, and possibly alter their learning behaviours.

Preparing to Teach Architecture Online: The Hurdle of the Design Studio

Helen Walpole
Curtin University

"Technology is transforming the practice of architecture and design from the conceptual stages right down to the actual construction" (Bender 2005). Recent technological developments in educational delivery have the ability to transform and redefine teaching in the discipline of architecture. To be able to offer a complete Architecture course online, the unique requirements of the practical design studio must be addressed and supported in the online environment. This poster sets out to illustrate what these features are and the process by which an Australian university has maintained the pedagogical requirements of the learning space.

Keywords: architecture, virtual design studio, design studio pedagogy

Introduction

The opportunity to deliver the Bachelor of Architecture and Master of Architecture as online programs was presented to the School of Built Environment and the Department of Architecture in 2011. The delivery scenario of the practical design studios – an integral, long term component of architectural learning, is a collaborative, creative and tangible space. The pedagogy of this practice was seen as one that could not be replicated, replaced or improved upon in an online learning environment. This poster explores the history of the architectural design studio, the pedagogy underpinning this approach and how we intend to translate a face-to-face design studio to the online environment.

The History of the Virtual Design Studio

The Virtual Design Studio (VDS) refers to a networked studio computer mediated and supported, distributed across space and time to participants in different locations (Broadfoot and Bennett 2003, 4). Virtual design studios, used since the mid-1990s, have influenced not only the role of the educators but also pedagogical models and outlooks (Shao, Daley and Vaughn 2007, 919). However it is important the pedagogical features and learning outcomes that are critical to successful learning in a face-to-face studio are replicated in the online design studio. The virtual design studio is by no means a new way to conduct design studios; they have been set up and used in several ways including asynchronous and synchronous delivery, and using various tools and e-technologies.

The Pedagogy of the Virtual Design Studio

The same fundamental questions asked of traditional design studio pedagogy need to be asked in the virtual design studio environment with the additional consideration of the possibility of a more radical, innovative and dynamic pedagogy being identified and delivered (Reffat 2007). Although there is a change in communication *methods* in an online environment, the learning tasks, outcomes and environment are the same, as is the importance placed on the communication between student and teacher. Both Schön (1987) and Kvan (2001) uphold that *one-on-one* communication is essential for exposure to the *tacit* knowledge inherent in designing. The VDS must be a highly interactive, collaborative learning environment allowing students to digitally display their work, including sketches and physical models, for critique from staff, industry professionals and fellow students.

Translation of design studio to the online environment

The infusion of digital media into practice of design and architecture is changing how the design process is carried out, what is designed (ie: artefacts), and the culture of design education (Reffat 2007). Students will set up a social network page using Ning and then join a 'special interest group' or 'community' for their unit. Ning was chosen not as 'another social network', rather to provide a tool that harnesses the engaging power of social networking for interaction and communication. Using Google SketchUp students will sketch their designs in 3D and then geo-reference them in Google Earth. The students will then create a physical model and produce a 5-10min video of the model and upload their sketch, link to Google Earth and the video of their model to their

Ning page. Alternatively the video can be uploaded to YouTube and embedded directly to Ning. Critique and online feedback by tutors, peers and industry professionals will take place through Ning.

What next?

The online architecture course will be delivered in study period 1, 2013. We will then conduct a full review of how the course was delivered, taking into account feedback from students, staff and industry professionals and make any enhancements if necessary.

Ready for m-learning? Access to mobile devices by tertiary students studying Japanese

Dr. Yasuhisa Watanabe
Asia Institute
The University of Melbourne

This paper reports on the ownership and use of computer hardware, including smart phones and tablet computers, among the students learning second year level Japanese at a university in Australia. The survey of 160 students shows that these mobile devices are taken up rapidly by current students, and are gaining popularity as a method of accessing study-related materials. Owners of a tablet computer seem more likely to use it for their education purpose. Yet, the significant majority of students still seem to prefer using desktop computer at home to access the university's Learning Management System, indicating that students are selective about their use of technologies for different purposes. The foundation for implementing m-learning at tertiary level seems to be almost set from the hardware point of view, but the students' pattern of using the hardware must also be taken into account when developing m-learning contents. (145 words)

Keywords: smart phone, tablet computer, ownership, use, survey, language learning

In the last 5 years, two products, iPhone and iPad, have given us alternative ways to interact with the world, organise our lives and obtain information. Both items have enabled us mobile access to the internet, and invited other companies to introduce similar products, thus created two new categories of technology that were not readily available to general population previously. Devices in both categories have penetrated the market rapidly. Telstra, an Australian telecommunication provider, claims that in 2011, 46% of mobile phone owners in Australia own a smart phone and this will continue to increase in the future (Telstra, 2011). Tertiary students are no exception to this trend. The learning in the future will most definitely utilise these technologies. Various mobile learning (m-learning) contents have been developed and delivered, capitalising on this trend (e.g., Cochrane & Bateman, 2010; Kinash, Brand, & Mathew, 2012).

However, despite being referred to as 'Digital Natives' who grew up surrounded by digital technologies and who are always ready to learn and processing information (Prensky, 2001a), not all digital natives who are now entering tertiary education are equally capable of using the latest mobile devices nor adept at learning at any time (Kennedy, Judd, Churchward, Gray, & Krause, 2008). In order for m-learning to be effective, students' access to, their level of familiarity with, and their preference and patterns of using different technology that they have must be considered (Kennedy *et al*., 2008).

The data analysed in this paper was collected as a preparation for upcoming development and implementation of m-learning program to enhance the learning of Japanese language. Through analysis, this paper intends to find out what array of technologies the students in 2012 own, how the available technologies are used by them, and whether there is a space for educational contents to enter into students' time and lifestyle via these technologies. It will also draw comparisons from the similar survey conducted at the same university in 2006 (Kennedy *et al*., 2008) to see how the introduction of the two categories of technologies, i.e. smart phones and tablet computers, have affected the students' use patterns of other technologies.

Background

Although smart phone ownership is spreading rapidly among students, there does not seem to be a clear definition of a smart phone. However, modern smart phones seem to share the following common features in addition to being able to make a phone call: data communication capability through applications such as a web browser, an email client and a calendar, an ability to compose and view documents, an ability to view and play photos, music and video clips, a camera to take photos and videos, and a LCD touch screen which doubles as touch keyboard (Incept Inc., 2011). Further, a user can add extra functions to their smart phones by downloading applications, or 'apps', such as foreign language dictionaries and games. A tablet computer can be described as a larger version of a smart phone without the ability to make phone calls (Incept Inc., 2012). With a larger screen, a tablet computer can be used as a substitute for a larger desktop or laptop computers (Telstra, 2011). In addition, the touch screen on tablet computers and smart phones can record where on the screen was touched, and when recorded continuously it can act as a digital notepad. With fingers and/or stylus pen, a user can create a note and send a digital copy to other users via the internet.

With the development of data communication infrastructure, users of smart phones and tablet computers are able to access the internet anywhere in the world where there is a mobile phone coverage or a WiFi access point. This capability can make smart phones and tablet computers ideal tools to not only deliver m-learning contents, but to ask students to interact with their teachers and peers. Especially for learning a language, where an extended amount of exposure to the target language is necessary for memorising and constructing another system of language, m-learning or Mobile Assisted Language Learning (MALL) is an attractive option for both students and teachers to increase contact hours. However, development and implementation of MALL activities will be limited by the students' access to mobile devices and use patterns. Surveying potential clients seemed appropriate to determine how students use different types of technologies for their study and other needs.

There are three studies that surveyed students' ownership and use of various technologies including mobile devices in Australian higher education context. Oliver and Goerke (2007) surveyed 413 students in 2005 and 290 students in 2007. In both survey they asked students about ownership of four mobile devices: laptop computers, handheld computers (PDA), mobile phones and portable MP3 players (e.g., iPod). It was found that in both survey just less than half of the respondent owned a laptop computer, less than 10% owned a handheld computer, while more than 96% owned mobile phones. They also found that majority of students (93.4 in 2005, 86.6% in 2007) use the online resources for study purposes. Although it is not stated how these students access the internet resources, one would imagine it was done from a desktop computer, given that mobile internet was not widely available in those days.

A larger scale study was conducted by Kennedy et al. (2008). They surveyed 2120 first-year students in 2006 at the University of Melbourne about their access to various technology hardware, including mobile phones and desktop computers, and use of them to access the internet resources. They found that 96.4% of students had unrestricted access to a mobile phone, 89.5% to a desktop computer, 63.2% to a laptop computer, and 10.8% to a PDA. Over 90% of students responded that they use the internet for study purpose, and most of them do so on daily or weekly basis. However, when asked about accessing the internet from their mobile phones, either for study purpose or otherwise, only 32.2% responded affirmatively.

Both studies mentioned above occurred before the introduction of the smart phone and the tablet computer. Fujimoto and Stockwell's study in 2010 surveyed 180 students studying various languages (Fujimoto & Stockwell, 2012). Their study also showed that more than 96% of students own mobile phones and more than half of them readily use them to access information on the internet. What was interesting was that almost 4% of students being surveyed do not use their mobile phones to make phone calls, meaning their use is limited to sending and receiving text messages and accessing the internet. However, the distinction between smart phones and ordinary mobile phones were not made in their questions. The ownership of tablet computer was not questioned either.

Aiming at using a smart phone to implement MALL activities in the near future, the students' ownership of smart phones will be surveyed in this study. Further, the students' use of various mobile and other technologies to access internet resources for study purpose will be included in the survey questions. Finally, students' willingness to use their smart phones and mobile phones for learning Japanese will be asked.

Methodology

Participants

Data used for this analysis was collected from students undertaking second-year-level Japanese subject at the University of Melbourne in May, 2012. Out of 190 enrolled students, 160 students participated to the survey. All participants were aged between 17 and 22 at the time of survey, thus belonging to 'digital native' generation.

At the University of Melbourne, students can take Japanese language subjects as their major or minor study area or as breadths subjects. All students at the university are encouraged to take 4 subjects from outside their home faculties, and this is how the majority of the students access Japanese subjects. Out of 160 participants, 131 (81.9%) indicated they are in this category, outnumbering both students studying Japanese as their major (21, 13.1%) or minor (7, 4.4%) area of their study. Among the teaching team, students in this category is said to spend less effort and time on their Japanese study because it is not their major study area.
The male/female ratio was close to even, with 70 male participants (43.75%) against 90 female (56.25%), while the number of international students was not as high as expected (59 participants, or 36.9%).

Procedure

A 1-page questionnaire, containing questions about students' access to, frequency and location of using various technologies and their likeliness to use their mobile devices in the m-learning or MALL activities being developed in the near future, was used. The format of the questions and the technologies included in the questions were selected following Kennedy *et al.*'s study (2008) in order to draw direct comparisons from their survey in 2006 to see the changing landscape of technology use over the 6 years at the same university. However, some items of technologies were substituted to reflect the technological development over the 5 years. For example, PDA which attracted the least proportion of affirmative answer in 2008 was dropped in favour of the two pieces of new technology, i.e., smart phones and tablet computers. The range of activities students conduct on-line was reduced to what can be done on mobile devices and substituted to reflect the possible use of the devices for a language learning purpose.

The anonymous questionnaire was distributed during a tutorial in May, 2012. There were 9 tutorial groups this year, each containing 16 to 22 students. The tutors in each tutorial group distributed the survey and were asked not to give specific instructions on answering the questions, other than to make general comments such as "students in this course seem to use their smart phones a lot during the tutorials." The students then had about 5 to 10 minutes to complete the questionnaire during the tutorial, before returning it to their tutors. The main researcher was not present during this time.

Results

Students' access to technology

Students were asked about their ownership and the access to a range of technology hardware. Three choices, unlimited access, limited access and no access, were given to each of the following devices: smart phone (e.g., iPhone and Android phone), ordinary mobile phone, tablet computer (e.g., iPad, Galaxy Tablet), laptop computer, desktop computer, and MP3 player (e.g., iPod). Smart phone and mobile phone are asked as separate items in order to see the penetration of the smart phones to this group of students independently from the older-generation mobile phones, although the distinction between them were not made explicit other than the examples given before. Students were advised to select 'Unrestricted access' if they own the device, and 'Limited access' if they use a shared facility.

Table 1: The percentage of students who owns or have access to mobile devices.

	2012			2006*		
	Unrestricted access	Limited access	No access	Unrestricted access	Limited access	No access
Smart phone	76.3	7.5	16.3			
Mobile phone	55.6	5.0	36.9	96.4	0.9	1.5
Tablet computer	22.5	10.6	66.9			
Laptop computer	84.4	8.8	6.9	63.2	10.0	24.0
Desktop computer	46.9	19.4	33.8	89.5	4.9	3.7
MP3 player	72.5	6.3	21.3	68.9	5.7	23.3

* The data from 2006 adopted from Kennedy *et al.* (2008)

Table 1 shows that majority of students have unrestricted access to the devices asked about, other than tablet computers. More than one in four students now owns a smart phone, while the ownership of ordinary mobile phone has dropped to 55.6%. Further analysis shows that 39.4% of students own both a smart phone and a normal mobile phone, while 0.6%, or 1 student, indicated that he/she does not have an access to either. The percentage of students who answered they only have access to a mobile phone, but not a smart phone or a tablet computer, was 10%.

Within 2 years of being on the market, tablet computer has penetrated a third of student population; 33.1% answered they either own or have access to a shared tablet computer. None of them answered that they have an unlimited access to a tablet computer on its own; of 36 students who answered they have an unlimited access, 35 (97.2%) indicated they also have an unlimited or limited access to a laptop computer and 27 (75.0%) indicated they also have an unlimited or limited access to a desktop computer. Twenty-six, or 72.2% of students indicated they have an access to all three types of computers.

When compared with the data from 2006, the access to a desktop computer has significantly dropped, with 33.8% claiming they do not have access to a desktop computer. In comparison, the access to a laptop computer has increased by around 20%. No student indicated that they do not have access to either a desktop or a laptop computer.

The proportion of students who have access to a MP3 player did not change significantly. Although a slight increase in ownership percentage is observed, it can be attributed to the difference in the size of participants between the two studies.

Frequency of use

Table 2 shows what proportion of students use their mobile devices for different activities. The question did not specify which device is used for a particular activity, but asked the students' general tendency to do the various activities from their mobile devices. Although some students indicated which device they use for each activity, they are not reflected to Table 2.

Table 2: Percentages showing how often students use mobile devices for different activities.

<table>
<tr><th></th><th colspan="4">2012</th><th colspan="4">2006*</th></tr>
<tr><th></th><th>Daily</th><th>Weekly</th><th>Monthly</th><th>Not used</th><th>Daily</th><th>Weekly</th><th>Monthly + over monthly</th><th>Not Used</th></tr>
<tr><td>Make phone calls</td><td>75.6</td><td>18.1</td><td>4.4</td><td>0.6</td><td>76.2</td><td>16.1</td><td>4.3</td><td>3.4</td></tr>
<tr><td>Send/receive SMS</td><td>91.9</td><td>6.3</td><td>1.3</td><td>0.0</td><td>79.5</td><td>13.2</td><td>3.1</td><td>4.1</td></tr>
<tr><td>Send/receive email</td><td>58.8</td><td>23.1</td><td>3.8</td><td>13.8</td><td>7.4</td><td>5.9</td><td>10.9</td><td>75.8</td></tr>
<tr><td>Take digital photo/movies</td><td>36.3</td><td>31.9</td><td>20.6</td><td>10.6</td><td>32.2</td><td>25.0</td><td>12.6</td><td>30.1</td></tr>

<tr><td>Take notes for study purposes</td><td>18.8</td><td>25.0</td><td>4.4</td><td>51.3</td><td></td><td></td><td></td><td></td></tr>
<tr><td>Listen to music/podcast</td><td>70.0</td><td>5.6</td><td>2.5</td><td>21.9</td><td></td><td></td><td></td><td></td></tr>
</table>

* The data from 2006 adopted from Kennedy *et al*. (2008)

The use of mobile devices to make phone calls, regardless of the type of phones, did not change greatly from 2006 data. However, the uses of mobile devices for other activities have increased since 6 years ago. The uses of mobile devices to send/receive emails have increased dramatically, from 7.4% in 2006 to 58.8% in 2012. Furthermore, mobile devices are used much more frequently to view websites, both for study and private purposes. While the data in 2006 only surveyed students for their experiences in using information from the web, the students in 2012 appear to use the web to gain information for their study as well. Unfortunately the data does not show the quality of students' experiences viewing various websites.

Students in 2012 seem more open to using their mobile devices for their study purposes. It is significant to see almost half of students have used their mobile devices to take notes for study purposes, and 43.8% on more than weekly basis. In language courses, almost 4 in 5 students have used their mobile devices as a dictionary, and 45% of them on daily basis.

These increases could be the result of enhanced capability of new mobile devices, especially smart phones and tablet computers, to readily access the internet and handle larger amount of texts on their larger screen. To check this, the data gathered from the owners of tablet computers and smart phones are contrasted with the students who do not have access to these devices. Tables 3 to 6 shows the percentage of students accessing email, accessing websites for both study and other purposes, and taking notes for study purposes according to their access to a tablet computer, smart phone and ordinary mobile phone.

Table 3: Percentages of students accessing email according to their access to mobile devices.

		n	Daily	Weekly	Monthly	Not Used
Access to a tablet computer	unlimited	35	65.7	28.6	0.0	5.7
	limited	17	70.6	17.6	0.0	11.8
Access to a smart phone	unlimited	121	66.1	23.1	3.3	7.4
	limited	12	50.0	25.0	0.0	25.0
Access to a mobile phone only		16	25.0	12.5	12.5	50.0

Students who have access to a tablet computer and a smart phone appear to send and receive emails from their mobile devices more often than students who only have access to an ordinary mobile phone. However, more students from the mobile phone only group are accessing the email from their mobile phones compared to students in 2006, as shown in Table 2.

Table 4: Percentages of students accessing websites for study purposes according to their access to mobile devices

		n	Daily	Weekly	Monthly	Not Used
Owns a tablet computer	unlimited	35	62.9	28.6	2.9	5.7
	limited	17	29.4	47.1	5.9	17.7
Owns a smart phone	unlimited	121	47.9	36.4	5.0	10.7
	limited	12	41.7	25.0	16.7	16.7
Owns a mobile phone only		16	18.8	18.8	6.3	50.0

Table 5: Percentages of students accessing websites for other purposes according to their access to mobile devices

		n	Daily	Weekly	Monthly	Not Used
Owns a tablet computer	unlimited	36	88.9	8.3	0.0	2.8
	limited	17	76.5	17.6	0.0	5.9
Owns a smart phone	unlimited	122	83.6	12.3	1.6	2.5
	limited	12	50.0	33.3	0.0	16.7
Owns a mobile phone only		16	25.0	25.0	0.0	50.0

A significant majority of students with accesses to a tablet computer and a smart phone indicated they view websites both for study and private purposes in daily or weekly basis. However, students with an access to a tablet computer appear slightly more willing to use it for study purpose than students with an access to a smart phone on more frequent basis. For example, 92.3% of students with a tablet computer use it for study purpose on daily basis, as opposed to 89.6% of students with a smart phone. In comparison, only half of the owners of a normal mobile phone have used it to view websites for both study and private purposes.

Table 6: Percentages of students taking notes with their mobile devices for study purpose according to their access to mobile devices

		n	Daily	Weekly	Monthly	Not Used
Owns a tablet computer	unlimited	35	40.0	25.7	0.0	34.3
	limited	17	17.6	23.5	11.8	47.1
Owns a smart phone	unlimited	120	19.2	30.0	5.0	45.8
	limited	12	16.7	8.3	8.3	66.3
Owns a mobile phone only		16	12.5	6.3	0.0	81.3

Although there are still a portion of students who do not use their tablet computers and smart phones for a note-taking purpose, students with a tablet computer are twice more likely to use it on daily basis than owners of a smart phone and a mobile phone. Ordinary mobile phones are not used for note taking, although there seem to be some dedicated users of their mobile phones.

Learning on mobile devices

The next section asked array of questions to determine whether mobile devices can be a tool for delivering mobile learning, and students' willingness to use them to learn Japanese on the move. As shown in Table 7, when asked directly, 83.1% of students answered they would like to use their mobile devices to receive m-learning or MALL activities.

Table 7: Percentages of students willing to receive m-learning instructions on their mobile devices.

Yes	83.1
No	10.0
Maybe/No Answer	6.9

However, when asked where students use their mobile devices, and where they access the university's Learning Management System (LMS), a different picture emerges. Table 8 shows the percentages of students using their mobile devices in different situations, and Table 9 shows the percentage of students accessing the LMS from different locations. Multiple answers were allowed for these questions.

Table 8: Percentages of students using their mobile devices in different situations (multiple responses).

At home	49.4
On the way to/from uni	66.9
At uni during classes	14.4
At uni between classes	43.1
Weekend	25.0

Table 9: percentage of students viewing LMS from different locations (multiple responses).

At home from a desktop computer	96.9
From university computer lab	21.9
On the move from a mobile device	27.5

Approximately two out of three of students (66.9%) indicated they use their mobile devices on the way to and from the university, while 43.1% indicated they use mobile devices between classes on campus. Mobile devices are also used by 14.4% of students during classes, presumably for note-taking purposes. Almost half (49.4%) responded that they use their mobile devices at home. Interestingly, only 25.0% of students use them on weekends.

Table 9 shows that the vast majority of students access the LMS at home from desktop computers rather than from mobile devices, while 27.5% indicated they access LMS on the move from their mobile devices. The choice “at home from mobile devices” was not included in the survey. University computer lab is used by 21.9%.

Discussion

The findings confirm that ‘digital native’ students are not homogenous group (Kennedy et al., 2008). When a new piece of technology becomes available, it does not always completely replace the old ones, but leaves behind some who are comfortable with not using the new technology (Kennedy, 2011). For example, although tablet computers have been used by one in three students, their use patterns are widely varied. Some have embraced the technology in various aspects of their life, including study purpose; others seem to prefer the old methods of studying. The number of students with an access to smart phones has now overtaken the number of students with an access to ordinary mobile phones with limited functions. When providing m-learning activities for the current students, alternative accesses to the same materials must be made available, not just from equity point of view to those without an access to a smart phone, but to fulfil the different choices that students make.

The selective nature of ‘Digital Native’ students, in terms of what technology to use for their learning, is noted by other authors too. For example, Stockwell (2010) reports that when given a choice to work on the same task between a mobile phone and a desktop computer, students who initially chose to work on their mobile phone have changed to work on desktop computers during the project. He also reports that the students who worked on desktop computers showed a higher level of achievement than those who worked on mobile phones (Stockwell, 2010).

From the findings of this study, too, it is unknown whether students who participated to this study will use their mobile devices to engage in the proposed m-learning or MALL activities, despite their overwhelming enthusiasm to attempt such a mode of learning. Despite a wider ownership of smart phones and an increased access to the internet from the mobile devices, it has not translated to accessing study-related website, in particular, the university LMS. Although it can be accessed from smart phones, this author’s own experiences with viewing the LMS on smart phones show that the pages are difficult to navigate from the smaller sized touch screens on these devices. The issue of screen size is widely acknowledged by practitioners of MALL (e.g., Stockwell, 2010). Perhaps the current generation interface design of the LMS is not suited to the use from smart phones. The issue of user interface still remains despite smart phones having larger screens and more intuitional interfaces than the older generation mobile phones.

However, it is notable to see 45% of students use their mobile devices as a dictionary. This may include both accessing the dictionary website via the web browser and using dedicated language dictionary apps. From this author’s personal observation in tutorials, the latter is the case for majority of students, giving them an alternative to buying a dedicated electronic dictionary that was once popular among language learners and international travellers. The dictionary data used in these apps can be stored in the smart phone or accessed via the internet connection. There are pros and cons for both types of dictionary apps, but ability to connect to the internet is exclusive to dictionary apps installed on smart phones. Furthermore, students seem to like using these dictionary apps in classes. It can be suggested that developing a dedicated app to access LMS, such as Blackboard Mobile Learn (Kinash et al., 2012) may invite more access to information on LMS from smart phones.

Access issues aside, it is also notable to see that mobile devices are used at home by most students, and that preparation for university studies seems to take place the most often at home. The similar findings were reported when a wider population of Australians were surveyed (Telstra, 2011). It seems that despite ‘Digital Natives’ are always ready to integrate new knowledge (Prensky, 2001b), in order to learn systematically, as required by the current tertiary education system, they still need a place to spend time on the contents to be learnt in peace. It appears their mobile devices are used to access information that they need instantly when they need it, in addition to using their less mobile devices, such as desktop and laptop computers. This may also shed light on the fact that students who have unrestricted access to a tablet computer also have regular access to desktop and laptop computers. Using mobile devices ‘at home’ does not necessarily mean they are used ‘at a desk’; it can be used in bed or in toilet (Telstra, 2011). Students are selective about which technology to use for different purposes.

Finally, one question that is yet to be answered is how tablet computers will be taken up by ‘Digital Native’ students in the near future. The cost of tablet computers may be preventing some students from owning one, in comparison to smart phones which can be owned with small or no initial outlay.[1] While it seems clear that it will not replace desktop or laptop computers in the next couple of years, it is also evident that the students with access to a tablet computer are more likely to use it to access websites for study purpose, including the LMS, and even during the classes to take notes. This seems to be the technology that can be transferred to learning purposes easily. Follow up surveys in the future may find a different picture.

Conclusion

For now, this author is satisfied to see that the students are willing to use their mobile devices to receive m-learning instructions. However, the challenges ahead are to design m-learning and MALL tasks that are unique to smart phones and can be used from a simple interface, as seen in various dictionary apps. It may be the case that the learning of the future is something that is downloadable as an 'app' to the students' mobile devises.

At the same time, in order to sustain the current mode of tertiary learning, which demands students to synthesise and create new knowledge, learning contents to encourage quiet thinking and learning time is also necessary. Strategies to use mobile devices for such purposes should also be considered.

The future surveys will need to incorporate questions specific to user interface as this appears to affect students' willingness and frequency to access information on smart phones. To see the changing landscape of technology use by students, a continued study of similar kind is ideal in order to determine how best to incorporate technology in the teaching at higher education level.

This paper reports on a study that explored the engagement of 17 academic staff with video conferencing technology in four large first-year classes in higher education during 2011. While the video conferencing brought a number of benefits, its implementation was far from straightforward, raising many issues about whether it should endure, and if so, in what form. Using an insider research approach, this paper considers ‘grounds-eye’ perspectives from teachers involved with the video conferencing. The findings identify three key issues that affected the sustainability of the video conferencing: a lack of synergy between individual, pedagogical, and organisational levels; the adoption of ‘safe’ practices by teachers when faced with uncertain learning settings; and the endurance of the video conferencing in an altered form. The paper casts some doubt on the positioning of teachers as ‘future makers’, showing how teachers can retreat into established practices when technology creates uncertainty in an educational context.

Keywords: technological innovation, sustainability, teacher perspectives, video conferencing, insider research

Introduction

The sustainability of innovation remains a pressing concern in the educational literature (Haigh, 2012; Nichols, 2008; Southwell, Gannaway, Orell, Chalmers, & Abraham, 2005), and e-learning is no exception (Breslin, Nicol, Grierson, Wodehouse, Juster, & Ion, 2007; Gunn, 2010). While early enthusiasm can often accompany technological initiatives, many are transitory, struggling to endure past their initial development stage, particularly when funding ceases. To borrow an analogy from Haigh (2012, p. 20) who discusses scholarship of teaching and learning (SoTL) projects, a new initiative can be like a “…wild flower, which suddenly bursts into full and striking bloom, delights those in the immediate neighbourhood for a brief period of time, then fades rapidly and disappears”. This paper reports on a study that investigated teacher engagement with an institutionally driven technological innovation that was perceived to be problematic by teachers. While it can be argued that all innovation is problematic to varying degrees, this paper is significant because it follows an innovation that seemed particularly disruptive, endangering its longevity, and because it provides an insider view of technological innovation through the experiences of mainstream tertiary teachers.

Sustaining technological innovation

Innovation “involves learning to do something in a completely different way by developing new practices which are both personal and social”, often using new technologies that allow us to act in different ways (Somekh, 2007, p. 1). Sustaining technological innovation can be challenging and Gunn (2010, p. 90) highlights three central characteristics: it has to go through a “proof-of-concept stage” and show clear benefits to teaching and learning; it must have “proven potential” to be used beyond its original setting; and it must not be dependent upon only one or two individuals for its continued success. Finding a “single formula for sustainability” is problematic (Gunn, 2010, p. 92); however, Owston (2006) has identified numerous factors that can support long-term sustainability, including teacher and student support, teacher perceived value, professional development for teachers, and administrative support. When embedding and spreading innovation, it is important that: (1) leaders and managers have clear goals and a strong commitment to the innovation (2) there is a willingness in the learning context to undergo substantive changes to embed and sustain the innovation (3) there is ongoing-access to institutional and external support (4) there is access to and use of institutional and national systems for communication and planning and (5) risk-taking, change and dissemination are supported through the innovation's design (Southwell et al., 2005). These factors show that technological innovation occurs within a socio-cultural context, affecting individuals, classrooms, institutions, and national organisations (Somekh, 2007). Aligning differing (and sometimes conflicting) educational and organisational perspectives is crucial (Synder, Marginson, & Lewis, 2007), yet this level of collective action often seems difficult to achieve (Gunn, 2010).

Teachers as agents for sustaining (or impeding) technological innovation

Teachers are often positioned as "agent[s] of change" (Ertmer & Ottenbreit-Leftwich, 2010, p. 255), playing important roles in deciding whether an innovation endures or not (Blin & Munro, 2008; Hannon, 2009). While there has been a degree of optimistic rhetoric surrounding technological innovation, the adoption of technology may not be an "easy road to travel" for academics (Gunn, 2010, p. 94). Pedagogical innovation is often disruptive as "…it involves disturbing the established routines through which individuals and groups perform and continuously re-affirm their identity" (Somekh, 2007, p. 2). Indeed, using technology can entail a degree of risk; technical breakdowns can occur, distorting the innovation, leading to limited use of the technology (Hannon, 2009), and eroding teacher confidence (Cuban, Kirkpatrick, & Peck, 2001).

In order to better understand teacher engagement, many scholars have studied the drivers and barriers of technology use by teachers, identifying various inter-relationships between individual, pedagogical, and institutional factors (Birch & Burnett, 2009; Kennedy, Jones, Chambers, & Peacock, 2011). Some key factors are workload, time, knowledge and skills, staff development and training, tools and infrastructure, recognition and rewards, beliefs about teaching and learning, and institutional support (Shannon & Doube, 2003). There are complex relationships between teacher beliefs and practices (Bain & McNaught, 2006) with personal characteristics such as motivation to use technology, comfort with change, and willingness to take risks playing major roles in the uptake and use of technology (Birch & Burnett, 2009). In addition, the perception that there is little institutional recognition and few rewards for the use of technology can be a powerful inhibitor (Birch & Burnett, 2009).

While much is known about the factors that influence academics' use of technology, there has been a tendency to focus on early adopters, neglecting the experiences of mainstream faculty (Nicolle & Lou, 2008). Such examples of exemplary practice may not reflect the daily experiences for many teachers and learners (Convery, 2009). There is a continuing need to understand how mainstream faculty engage with technology (Nicolle & Lou, 2008); one way to meet this need is to conduct fine-grained studies that provide insider views of the day-to-day use of technology over time. Temporal perspectives can provide important insights about sustainability by revealing why academics continue to use (or reject) technology. This paper builds on the work of others who have explored innovations that have failed to thrive (see for example, Blin & Munroe, 2008; Hannon, 2009) by considering why teachers struggle or fail to sustain their use of a technological innovation over time. In this instance, the innovation under study is video conferencing – a useful choice considering that the field of video conferencing remains under-researched as a "hidden mode of delivery" (Lawson, Comber, Gage, & Cullum-Hanshaw, 2010, p. 307).

The study

Background

As a recently introduced technology, the video conferencing was a response to the formation of large first-year classes at an Auckland university. Previously, the same lecture had been repeated many times during the week to a cohort of more than 1000 students. Using the video conferencing, one expert lecturer was able to simultaneously connect with students in four different venues located on three campuses across the greater Auckland region. It was argued that the video conferencing was beneficial in two main ways: students were provided with flexible learning opportunities as they were able to attend a convenient venue rather than travel to a central location and staff workload could be decreased as fewer lectures were presented. However, during its first year (2010), the video conferencing initiative experienced numerous technical breakdowns, disrupting learning and teaching activity. At the conclusion of 2010, there was a sense that the video conferencing was not realising its full potential to support pedagogical objectives. In response, this study was proposed. The study had three main objectives: to deepen understanding of the complex relationships between teachers, pedagogy, and technological innovation; to enhance learning and teaching with video conferencing; and to explore the use of insider research as a methodological approach.

Methodology

The study aimed to provide 'backstage' access to mainstream teacher engagement with a technological innovation. To achieve this objective, a qualitative design was chosen that drew heavily upon contemporary ethnography by studying "real-life human behaviour to gain a unique understanding of the context and thought that informs such behaviour" (Murchison, 2010, p. 13). An insider research approach (the researcher being a member of the social group under study) was used whereby three of the seventeen participating teachers occupied the dual roles of participants and researchers (Westberry, McNaughton and Gaeta). Seventeen lecturers from four large first-year classes participated in the project over a 12-week period from February to June 2011 (one semester). A number of qualitative methods that supported an ethnographic approach were employed. Immediately after the weekly sessions using the video conferencing, the staff member teaching that day used research prompts to record a ten-minute (maximum) post-lecture recording of her/his experience using the video conferencing. To enrich the data, lecture sessions showing staff interacting with the video conferencing were discretely video-recorded by a technician (with permission from participating staff). Also, four group interviews scheduled at regular intervals provided opportunities to pursue interesting leads in the data. Finally, differing perspectives were obtained through interviews with key informants involved with managerial or technical dimensions of the video conferencing. A thematic analysis was chosen for this study which is defined as "…searching *across* a data set – be that a number of interviews or focus groups, or a range of texts – to find repeated patterns of meaning" (Braun & Clarke, 2006, p. 86). This form of analysis was considered appropriate because we wanted to create a rich description of the data to show key themes. Another benefit is that this approach has "theoretical freedom" in that it is not tied to any particular theoretical framework (Braun & Clarke, 2006, p. 78).

Findings and Discussion

The application of video conferencing did provide some benefits such as enhancing collaboration between staff, communicating consistent information to students, and decreasing the number of lectures presented by teachers. However, at the time of writing (June, 2012), the original video conferencing system had been replaced with Mediasite ™ (http://www.sonicfoundry.com/mediasite). While the concept of connecting lecture theatres had been proven as a useful way to engage with large groups of students, the initial technology had not. The following findings provide some initial insights into why the video conferencing was not sustained in its original form.

A lack of synergy between different organisational levels

The findings from this study suggest that misalignments at organisational, pedagogical, and individual levels affected the sustainability of the innovation. As funding for the video conferencing was not confirmed until late in the year, the technology had to be obtained and installed quickly over the summer months (January/February) when staff availability was limited. The video conferencing was to be used in the first semester (end of February), so there was little time for testing, trialling, and professional development of staff. Indeed, some of the equipment was still being installed when lectures began. The limited lead-in time between funding, installation, and use of the technology suggested a lack of alignment between different levels at the university, fuelling a sense of being unprepared amongst the staff. As lecturers moved, rather abruptly, into a changed teaching environment, it appeared that they lacked sufficient opportunities to negotiate their beliefs, practices, roles, relationships with other staff (including technicians) and identities as lecturers. This exacerbated the mismatch between their expectations and actual use of the video conferencing. Misalignments between different organisational levels resulted in a failure to provide an adequately resourced transition zone in which the new technology could have been better understood, and beliefs and practices could have been negotiated and conflicts reconciled.

Adapting to an uncertain environment by 'playing it safe'

The lack of preparation coupled with ongoing technical problems injected a sense of uncertainty into the lecture environment, affecting the ways teachers thought and acted as they made sense of this new setting. Many lecturers adapted to this uncertainty by avoiding risk and instead adopting practices that were perceived as 'safe' such as using the video conferencing as a tool for transmitting information to the students. One such example involved interactivity in lectures. Many presenting lecturers wanted to have two-way communication with all students, expecting to interact with students across the venues. These expectations were often unmet. Some presenting lecturers attempted to conduct inter-venue question and answer sessions; however, difficulties communicating with the venues (such as poor sound, loss of sound, or loss of venue due to technical problems) hindered this approach. Also, delays in venue responses were frequent and students were observed displaying restless and off-task behaviour as they listened to numerous questions from different venues. As ongoing problems were experienced, there was a move to limit inter-venue interaction as it entailed levels of difficulty and risk that were deemed unacceptable. However, by adopting 'safe' practices that reinforced transmission approaches to lectures, lecturers often expressed a strong sense of loss, perceiving that they were required to make many concessions with their beliefs and practices. There was a perception that technology was leading pedagogy rather than acting as a tool to support teaching and learning, and that lecturers were compromising their beliefs and practices to avoid disruptions in lectures. As one teacher participant noted, teachers were adopting "dumbed down learning outcomes". Rather than being agents of change, teachers often seemed to be retreating into established practices.

Sustaining the concept, not the technology

Despite difficulties, the use of video conferencing was sustained, although this point needs clarification. In this case, the concept of video conferencing was sustained, but the actual technology was not. This is probably because, in theory, video conferencing filled a basic need – to allow one expert lecturer to connect with multiple venues in large classes, facilitating the delivery of content. When asked, all teachers except one were adamant that they did not want a return to delivering five lectures a week (the previous system). The findings confirm Gunn's (2010) position that the use of a technology will be sustained if it passes a 'proof-of-concept' stage by bringing added value to teaching and learning. However, while the concept was proven, the actual video conferencing technology was perceived as highly problematic; another tool was required. This finding highlights the importance of distinguishing between the idea that lies behind technology adoption and the actual technology itself when considering the sustainability of technological innovation.

Conclusion

By obtaining 'grounds-eye' views of teaching with technology, this paper has shed some light on how a technology is sustained over time. The video conferencing initiative provided some benefits, and yet, a lack of alignment between individual, pedagogical, and institutional levels led to an uncertain environment in which teachers adapted by avoiding new ways of thinking and acting, instead opting to adopt 'safe' practices. The innovation has, to date, endured, and yet in a weakened or attenuated form that appears to reinforce transmission approaches to lectures. Innovation is often disruptive, and yet in this case, it seemed too destabilising. Perhaps teachers can be agents of change, but when innovation destabilises a context too much, it may trigger adaptive responses that reinforce existing practice.

Acknowledgements

We would like to thank our colleagues who generously gave their time to participate in this study during a busy teaching period. Support for this study has been provided by the Centre for Learning and Teaching (CfLAT), AUT University, Auckland, New Zealand.

University of New England

In this paper we describe a technology supported learning activity that was developed, implemented and evaluated in a postgraduate, online unit of study offered by the University of New England in 2011. A learner analysis and an analysis of the learning outcomes of the unit informed the development of this activity. The online activity was created within a Wiki and students completed it in the first few weeks of the teaching period. This design was intended to build social presence by encouraging ongoing interaction and engagement in the unit. A constructivist approach was utilised to facilitate this authentic activity in line with theories for learning futures. The activity provided scaffolding for subsequent assessment tasks in the unit. Students' outcomes and their feedback on the activity suggested it was successful in achieving the intended goals.

Keywords: Engagement, interaction, learning futures, lifelong learning, online activity, social presence

Introduction

The focus of this paper is a technology supported learning activity that was adopted for the first time in trimester three, 2011. It involved the development and implementation of an optional online activity early in the teaching period which was aimed at encouraging interaction and engagement in a postgraduate professional ethics unit of study. The design was intended to align learning outcomes with assessment tasks. A constructivist approach was used to engage students in a discovery process aimed at development of skills intended to enhance future studies and lifelong learning. The use of such online collaborative spaces has demonstrated benefits for learners in terms of encouraging active learning (Chickering & Gamson, 1987), and experimental problem solving, thus enabling students to develop the skills required to construct their own understanding. This approach aligns with a learning futures approach which is about "education and learning which is concerned with preparing individuals and groups to respond to the challenge of life" (Kehrwald, 2006, p. 4). Andres (2002) suggests that in group learning environments "students are frequently more motivated to work when there is an audience beyond that of the teacher" (p. 2). Students were surveyed at the end of the teaching period to evaluate the success of this activity.

Activity development

Daigre (n.d) suggests that the "key to instructional design is to work around the participants rather than the content" (p. 1). Keeping this in mind, the design project began with consideration of the learners enrolled in the program of study. This analysis was conducted utilising statistical data available through the University's Planning Office, and a review of admission procedures for the program. A selection of previous offerings of units in the program was also examined to determine general participation rates and level of interaction as well as technological experience and access issues for the cohort. Finally, an analysis of the unit itself in terms of learning outcomes and content was undertaken to inform the activity design.

Learner analysis

Historical data shows that the cohort enrolled in this unit largely consists of mature-aged students. Statistics show that almost 70% students are aged between 30 and 49. Gender distribution is relatively even. The unit (and the program) is offered in distance mode and online only at postgraduate level. The Graduate Certificate is the main entry point with almost 75% of students enrolled in this program. These students have completed an Advanced Diploma through TAFE, suggesting that a majority of students have limited experience studying in a tertiary environment, and they may have little or no experience in online studies. Admission requirements to the Masters program include completion of a three year degree or its equivalent in a relevant discipline, or completion of a Graduate Certificate in Professional Accounting. Entry into both programs requires at least two years full-time equivalent of relevant work experience and current associate membership of a professional accounting body. It can be assumed that students are familiar with the use of information technology applications as the unit is explicitly described as fully online, which implies students who enrol have a reasonable level of confidence and willingness to participate in studies using information technology as a means of delivery. Interestingly, the age range of the majority of students indicates that many will be 'digital immigrants' (Prensky, 2001), which could impact on the level of student interaction.

The program is a full-fee paying degree therefore personal motivation to succeed is high. While this is not the same as motivation to participate, it does indicate that students enrol in this program for personal benefit and self-improvement and, as such, would be interested in engaging in discussion activities with peers. A review of discussion boards in other units in the program supports this assumption. In addition, previous student feedback from a similar cohort revealed students' willingness to view material and multimedia resources online and to participate in discussion groups. However, students expressed concerns about participation in assessed group work, with a majority of students indicating that they would not 'enjoy' this type of task. Reasons cited included time and organisation issues, problems with participation levels and preference for individual submissions. This indicated that group activities would need to be carefully structured to encourage active participation and engagement.

Unit analysis

The unit of study – Professional Ethics – is offered online through a Learning Management System (LMS) accessible via the Internet. It is a compulsory unit in both the Masters and Graduate Certificate programs, so all students are required to complete the unit successfully to ensure progression. Ethical theories and concepts are an integral part of the content, with the main outcomes of the unit dependent on knowledge, understanding and application of these theories – '*identify and explain major ethical theories and concepts'* and *'employ ethical theories and concepts to analyse particular business activities'.* The content lends itself to the use of constructivist, authentic activities, particularly those which enable students to use knowledge relevant to their own situations (Brown, Collins & Duguid, 1989). In addition, to achieve graduate attributes relating to the unit, students are required to demonstrate communication and lifelong learning skills. The design of this activity was intended to address these attributes by "the development of...transferable skills, such as the ability to work with others and the development of written…communication skills" (Crowe & Pemberton, 2000, p. 1). The unit is one of the most challenging students complete in their programs as it requires critical engagement with the materials. Students are required to demonstrate their mastery of the content by developing and defending their own points of view with regard to contentious issues related to professional practice. Since there are very few 'black and white' solutions, the content is intellectually demanding.

Activity design

The activity was developed within the Wiki tool built into the LMS. This provided an asynchronous, collaborative space which displayed a structured view of postings which were utilised for further discussion surrounding the activity. As the unit enrolment was high, larger groups were necessary (n=8 to 10) but the group size was still considered small enough to assist in developing accountability as well as making the task more manageable (Harasim, Hiltz, Teles & Turoff, 1995, p. 30). As students did not have extensive experience in online studies, guidelines were provided which were intended to assist students in understanding the mechanics of the activity in terms of using the embedded Wiki tool. An example was also provided to demonstrate expectations.

The rationale for choosing this type of activity was to meet the following goals:

- Encourage students to interact more fully by developing social presence in the online unit early in the teaching period
- Engage students in the materials, by illustrating the 'real world' application of the ethical theories
- Provide an opportunity to work in groups and experience other points of view

- Provide scaffolding for the subsequent assessment tasks, especially the major assignment
- Provide the unit coordinator with an early indication of students' understanding of the foundational theories and concepts

The activity consisted of an exercise with the following steps:

1. Group members were asked to describe a workplace-related ethical situation or dilemma about which they had first-hand knowledge (due at the end of week 2)
2. Each student then analysed this situation by employing one of the core ethical theories introduced in the unit (due at the end of week 3)
3. Each student was then required to use a different theory to analyse a situation posted by another member of the group (due at the end of week 4).
4. Group members were encouraged to provide comments on others' analyses (to be concluded by the end of week 5).

Lecturer support consisted only of guidance and management of technical issues. As noted by Oliver (2002): "Effective online learning settings support knowledge construction and to do this they must provide contextually-authentic tasks as the basis of learning" (p. 3). As the ethical theories were an integral part of the unit (as noted above) in terms of the stated learning outcomes, a knowledge of the principles behind several theories and their application was required in order for students to develop a broader view of how one might act when confronted with an ethical dilemma in the workplace.

The activity was structured in a way that aimed to develop learner participation and collaboration, in line with Salmon's (2002) model which "provides an example of how participants can benefit from increasing skill and comfort in working, networking and learning online" (p. 10). It was intended that this approach would create social presence for students and encourage active dialogue. The asynchronous nature of this activity also encouraged reflection and thoughtful construction of contributions (Martyn, 2003) as well as enabling flexibility for students in participation scheduling (Smith, 2005). This was considered particularly important because the students were studying part time while juggling family and work commitments.

The structure of the activity follows Reigeluth's Elaboration Theory in terms of organisation and providing a meaningful context for students to build on knowledge. While supporting content was provided, the activity enabled a learner-centred approach by allowing students to choose the ethical situations and theories they preferred to focus on. The various steps in the activity were intended to encourage student reflection and analysis, and achievement of the learning outcomes through the alignment of instruction, online interaction and the subsequent assessment tasks. Elements of experiential learning were also present in terms of participation in the learning process and tasks based on practical problems and self-evaluation, while the design utilised aspects of constructivism and situated learning, through the presentation of authentic and knowledge building tasks. The use of personal experience supported the authentic nature of the activities as did the application of knowledge to a problem presented by another student. The activity supports learning for the future through the development of skills and approaches which will be essential to the development of active learning skills.

Conclusion

For students in this unit, most of whom were already working in the disciplinary field, this design provided an authentic and learner-centred activity which "focuses on giving the learner the ability to decide what he/she feels is important and relevant. A more dynamic design approach is more reflective of the types of challenges individuals will face when learning through experience and other informal methods" (Siemans, 2005, p. 4).

This activity addressed critical elements of successful online learning identified by Reushle, Dorman, Evans, Kirkwood, McDonald & Worden in terms of "cognitive strategies, learner-centredness, interactivity, collaborative learning and social presence" (1999, p. 1). The activity provided scaffolding for following assessment tasks in the unit, which included an online test, essay and exam.

Evaluation of this task was obtained through a student survey, unsolicited feedback from students as well as a review of students' final results. Student surveys indicated that the activity was useful preparation for further assessment tasks (very helpful: 70%; somewhat helpful: 23%). Comments from students confirmed the benefit of higher levels of interactivity in the unit and the value of seeing others' points of view. Moreover, those students who participated in the optional activity were more successful in the unit overall than those who chose not to participate. Students who did not complete this activity, but completed the unit had an average mark of

55% while students who did complete the activity and completed the unit achieved an average mark of 66%. The activity also provided the unit coordinator with an early indicator of the level of understanding of the ethical theories than has been available in previous offerings of this unit, thus providing an opportunity for additional clarification where there were misunderstandings.

The purpose of this concise paper is to propose, with evidence gathered through a systematic evaluation of an academic development programme in the UK, that training in the use of new and emerging learning technologies should be holistically embedded in every learning and training opportunity in learning, teaching and assessment in higher education, and not only as stand-alone modules or one-off opportunities. The future of learning in higher education cannot afford to allow Universities to disregard that digital literacy is an expected professional skill for their entire staff.

Keywords: learning design, professional development, reflective practice, situated technology use

Introduction

The Postgraduate Certificate in Professional Practice in Higher Education (PGCPP) is organized through the Centre for Learning Innovation and Professional Practice at Aston University in the UK. Like other similar programmes across the UK it provides the opportunity for new academic and academic-related staff to obtain a nationally accredited award which is of value for professional development and career progression. Until the last academic year, the use of new and emerging learning technologies within the process of studying the particular programme has been somehow been limited in that it promoted the use of institutionally supported learning technologies as a mechanism to develop the necessary technical skills to operate tools such as the virtual learning environments (VLEs – also known as learning management systems in Australia) and the e-portfolio platform. However, participants did not feel particularly empowered to experiment with new technologies in their own practice as a result of their participation in the programme. This appeared to be because of few opportunities and incentives to integrate new technologies in a context where workloads are full and research productivity is the priority (Gunn, 2011). The programme team decided, therefore, to revisit and restructure aspects of the core modules for 2011-2012 delivery, while resisting the temptation to introduce a specialised module on learning technologies. The new learning design aspired to provide a variety of learning tasks and extended practice opportunities for the participants to most effectively develop as critical users of learning technologies in their own disciplines (Beetham & Sharpe, 2007). The paper presented here briefly describes the learning design and presents the preliminary findings from the first year of its implementation using evidence gathered through a systematic evaluation from two cohorts of participants.

A brief note on the underpinning learning principles

In the context of good professional practice academic and anticipating future challenges, development programmes, such as the PGCPP, should empower participants to move beyond the development of Information Literacy to the creation of Critical Digital Literacy (Wenger, White & Smith, 2009). In practice this means that teaching and support staff will be offered opportunities for personal and team activities that help them understand the affordances of learning technologies (Gibson, 1977) and translate technology-enhanced learning concepts and ideas into practical and workable solutions for use with students and staff (Gunn, 2011). It also means that participants will move from '*learning before doing'* to '*learning while doing'* with the use of technology (Cowan, 2006). This situated learning opportunity is the most effective way in which participants can achieve higher order thinking, which in turn is the differentiator for future successful organisations (Strattner & Oblinger, 2008) and sustainable futures. This latter point is an important one to keep in mind, given that many institutions often offer a one-off opportunity for training in the understanding and use of learning technologies in the form of stand-alone modules as part of a PG Certificates, PG Diplomas or MSc programmes. The importance of embedding learning technologies in an holistic way, and not as one-off modules or sessions, has attracted renewed attention by professional bodies such as the Staff and Educational Development Association and the Heads of E-learning Forum in the UK, both of which have recently (during 2011) devoted conference themes and development days on this topic. It was this idea of 'learning while doing' with the use of technology that inspired our new approach of the PGCPP.

Our PGCPP holistic learning design framework

The PGCPP programme consists of three core modules, which are delivered in a blended learning format (a combination of face-to-face taught sessions and online learning opportunities) and are assessed separately using clearly defined assessment criteria. Figure 1 below offers an overview of the modular structure of the programme and the core activities and approaches used. The use of new and emerging learning technologies is central to all modules and all activities of the programme. For example, in Module 1 participant are asked to develop critical incidents reports and make direct learning journal inputs considering their digital participation in the programme from the point of view of the student and of the learning designer and tutor. They can also choose to be observed in both face-to-face teaching settings and in virtual settings, where a member of the programme team is shadowing their online asynchronous or synchronous 'classes' and then debrief them as in normal teaching observation settings. The overall aim is to critique, evaluate and re-use ideas experienced in the PGCPP in their own disciplines. The overall expectation is that by embedding learning technologies in the course, as participants would be expected to use them in their own practice, academics would feel empowered to transfer these skills in their own learning designs. To support this expectation, participants were offered the opportunity in Module 2 to work, during full curriculum development days, towards re-structuring parts of whole modules and to consider critical and situated use of technology in their own discipline. Finally in Module 3 there were offered the opportunity to learn about specific research methods used to evaluate learning and teaching with the use of technology, carry out an original piece of research and write it up for dissemination in a conference or a journal article.

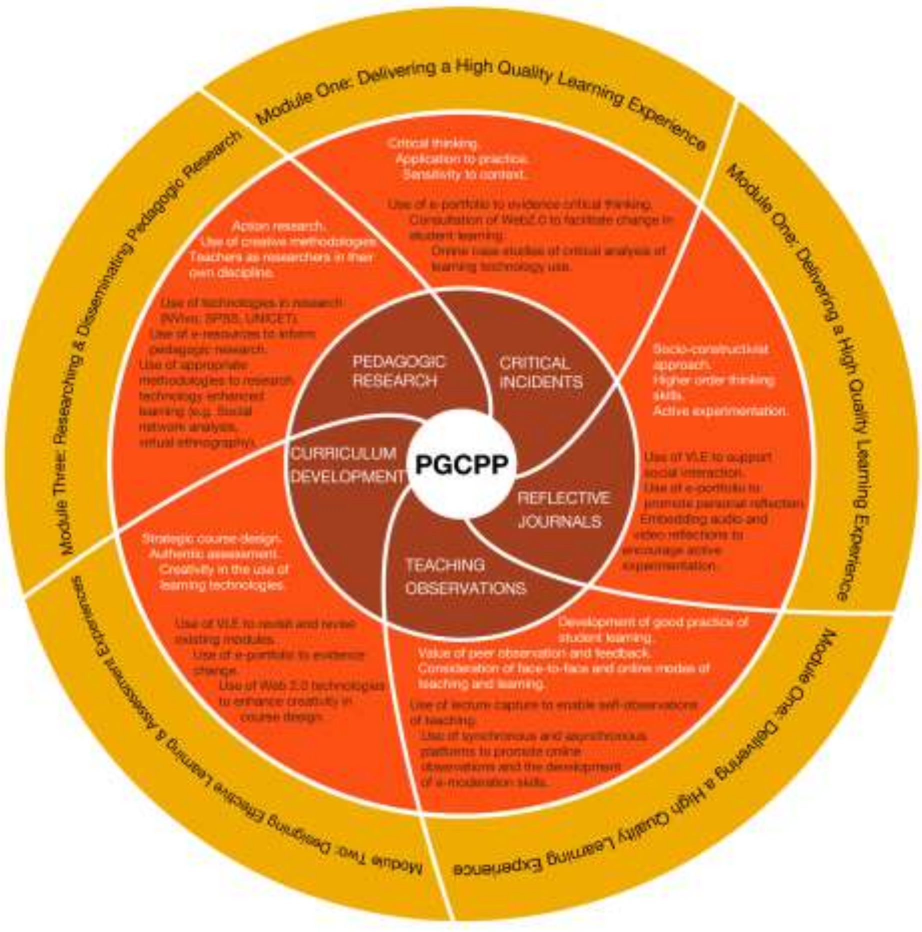

Figure 1: The PGCPP Learning Design Framework

The evaluation of the first year implementation

During the academic year 2011-2012 two cohorts of participants (No=37) commenced the PGCPP in its new structure. In order to find out how their attitude towards embedding learning technologies in their own discipline areas has changed over the duration of the programme we conducted a survey followed by a series of focus group interviews, which were transcribed and partly analysed using content analysis. The purpose of the anonymous survey and the interviews was to provide a broader data set and included a number of questions around the relationship between attitude towards discipline-based teaching and perceptions of student-centered learning. We used a revised version of the Teaching and Learning International Survey (TALIS) instrument to collect the quantitative data. There are answers to two questions that are worth summarizing for the purpose, and economy, of this paper, which were also elaborated in the interviews: 1. Considering your participation in the PGCPP, to what extent has it directly led to changes in your teaching of students with the use of new technologies in the current academic year? 2. In your opinion, how much innovative teaching and learning practices with the use of new technologies should be considered when you plan your teaching for next academic year? The findings from both questions are summarised in Figures 2 and 3 respectively.

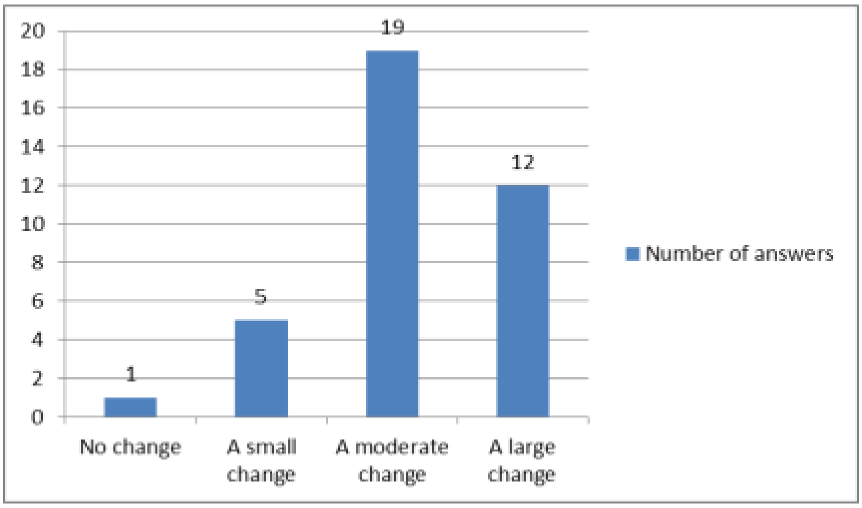

Figure 2: Your teaching of students with the use of new technologies in the current academic year

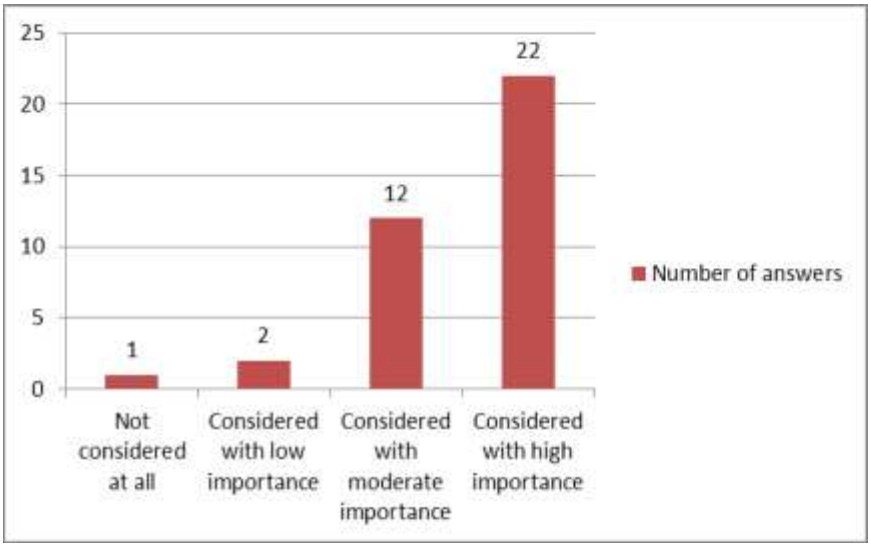

Figure 3: Your teaching of students with the use of new technologies for next academic year

So what?

The findings from the survey indicated that the majority of the academics involved in the holistic learning design framework had either already tried out (during the duration of the PGCPP) or are considering embedding learning technologies in their learning design for next academic year. It was interesting that in the question about embedding new technologies for next academic year the majority (no=22) of participants stated that they would consider it with high importance. This is a very encouraging finding especially as the majority of them, during their initial reflective entries in Module 1, expressed serious concerns regarding the 'intensive' use of technology in a course for novice academics and that they are 'being expected to run before they can walk'. Nonetheless, their reflections in module two showed a dramatic (positive) change in their attitude towards both the value of technology from the tutors' point of view and that of the learners. All of the learning designs submitted as part of their portfolios included new learning technologies to support learning and assessment of students with clear rationale for doing so. This was also the case for the few participants who are still skeptical about learning technologies, but who decided to at least consider them in their theoretical designs for next year. The difference between the submissions of these two cohorts, when compared with the submissions from cohorts in 2010-2011, is extremely high when considering both the creative use of technology that goes beyond the usual implementation of a VLE to run multiple-choice quizzes or add simple multimedia files.

Although a presentation of our qualitative findings would add significantly to the trustworthiness of our claims in this paper, the analysis is still undergoing and therefore a follow up publication of this study will summarise all the key findings. We would like to end, though, with two illustrative quotations from two of the most skeptical academics who openly in the interview characterized themselves as being technophobic:

> My approach to learning activities and use of new technologies has changed in a positive way over the last few months. Participation in the online activities and discussions has given me an insight into how I might use online discussions in my own teaching, that's something I would not consider had I not experienced this mode of learning as a participant. (Participant from the School of Life Sciences)

> a great merit of this PGCPP is my own experience of flexible learning with the use of technologies while employed and at the same intensity (60 credits in a year) as my Programme Participants will experience for 3 years! (Participant from the School of Engineering)

It became clear to us that continuity and diffusion of innovation with leaning technologies is better achieved at a programme as opposed to module level, and when supportive organizational structures are in place they empower academics to implement change. Sheward and Hamilton (2012) articulate that more participant-generated technology enhanced learning activities need to be incorporated into such programmes. We feel that, based on our research, strategically organized courses like the PGCPP are the ideal places for this diffusion to take place.

Consulting the ‘oracle’: Using a Delphi process to facilitate change to a blended learning model for rural mental health professionals’ recruitment

Julie Willems
Department of Rural and Indigenous Health,
Monash University

Keith Sutton
Department of Rural and Indigenous Health,
Monash University

Darryl Maybery
Department of Rural and Indigenous Health,
Monash University

What happens when time, staffing pressures and a reduced funding base begin to impact on considerations for the future deployment of a successful university-based program promoting professional career options in rural mental health for completing students? This paper outlines the initial steps of shifting the Gippsland Mental Health Vacation School (GMHVS) from a successful week-long face-to-face program to a blended, collaborative and interactive model, distributed across space and time. Further, this blended learning approach encompassing social media opens the possibility to enable greater student numbers to participate in future GMHVS programs.

Keywords: mental health professions; rural recruitment; students; service providers; social media; blended learning

Introduction

Mental health professionals encompass a range of occupations including nurses, psychologists, social workers, and occupational therapists. Their collective involvement in the active promotion and treatment of mental health issues are important in terms of a holistic and interprofessional approach for the patient. Individually they also bring important skills according to their professional training. However, recruiting and retaining workers is a major challenge in rural and remote Australia (Sutton, Maybery & Moore, 2012). There are multiple reasons for this situation ranging from concerns that rural is ‘second best’ due to anxieties over access to services and fear of isolation (Eley, Young & Shrapnel, 2008), in addition to trepidation over such personal issues as finding a spouse, rewarding employment opportunities and quality education pathways for children (Rosenblatt et al., 2006).

The Gippsland Mental Health Vacation School (GMHVS) was developed by Monash University’s Department of Rural and Indigenous Health (MUDRIH) with the aim of attracting students studying at metropolitan tertiary institutions to working in the rural mental health field (Sutton, Maybery & Moore, 2012). The program has now run successfully over four cycles since 2010 and has received positive qualitative and quantitative feedback from both the participating students and representatives of Gippsland service providers. However the GMHVS program is now being challenged on a number of levels, including funding insecurity, time pressures and future staffing options. There is also a desire to create a more self-sustaining, less time-intensive program that can be added to rather than recreated each time that the program is offered. This paper outlines the initial steps of shifting the successful face-to-face program to a blended, interactive model, distributed across space and time. The approach is being refined via the Delphi Study outlined here.

Delphi Study

A Delphi Study is a structured process for the purpose of collecting and condensing group knowledge or feedback by means of a series of ‘rounds’. There are usually three rounds to a Delphi Study and, at the end of each round, the feedback is summarised and presented back to the participants for rating. The participants are also able to provide further comments in this procedure. Through this cyclical process of refinements, group consensus is reached. In the current Delphi Study, following ethics permissions, data has been gathered from two research cohorts as stakeholders in the program: the GMHVS 2012 students, and representatives of the participating Gippsland mental health organisations. This information will give direction and guide the structure of the future GMHVS blended program offering.

Social media

While the results of the Delphi rounds are still undergoing final analysis, a clear theme emerging from both cohorts' responses in Round 1 was the desire for the establishment of continuing contact following the end of the program. As the participants are geographically dispersed, it was felt that the creation of a virtual group via social media might be the best solution. The advantage of social media is that in breaking down access barriers it also enables "communication among ever-widening circles of contacts [and] inviting convergence among the hitherto separate activities of email, messaging, website creation, diaries, photo albums and music or video uploading and downloading" (Livingston, 2008, p. 395). It serves to attract people, holds their attention, impels their contribution, and brings them back as recurring visitors (Johnson, et al., 2011, p. 12 paraphrased). To this extent, the initial step in moving to a blended GMHVS program has been the creation of a group in the social media site *Facebook* (www.facebook.com), chosen as all students had existing accounts. Of the different types of groups in *Facebook*, a 'closed' group was chosen in the first instance. In a closed group, the name and constituent members are visible to everyone, however the content is visible only to members and access to the group is moderated by the administrator of the page. Constituent group members include the GMHVS 2012 students, representatives from the Gippsland mental health service providers, plus MUDRIH staff members.

To date, from positive comments written, the GMHVS 2012 *Facebook* group has enabled the participating students to feel that they belong to a supportive collaborative geographically-dispersed, yet virtually-present professional community; that they can participate in activities promoting rural lifestyle for post-qualifications employment options; that they can respond to the reported job vacancies listed by group members; and that they can share individual updates including the attainment of rural mental health employment placement 'success stories'. As an exemplar of this, one student member wrote on the group's wall "Just thought I'd let you all know that I've been offered [a job] at [one of the Gippsland Mental Health Service providers]! Never would have happened without the vacation school, so thankyou all!"

Conclusion

Moving an educational program from place to space can be a daunting process. The first steps in the successful management of this change process has been to seek the feedback of the key stakeholders involved – the GMHVS student cohort, and representatives of the Gippsland mental health service providers – by means of a Delphi Study. A clear research finding emerging from Round 1 of the Delphi process has been the need for virtual connectivity and community following the program. The early indicators of co-opting a social media site for this purpose suggest that an exciting, dynamic blended model is in the forming, and one which involves not only stakeholder 'buy-in' but also their active participation. This is a work in progress.

Sustainable futures for learning in a climate of change: Mobile apps, social media, and crisis informatics during emergencies and disasters

Julie Willems,
Department of Rural and Indigenous Health
Monash University

Emergencies and disasters are different types of crisis events which can affect students and staff in their on-campus roles and off-campus activities. In such events, mobile technologies, mobile software applications (apps), and mobile social networks are becoming increasingly relied upon to communicate, to swiftly send and received information and images, to deliver learning moments, and to check the safety of colleagues and friends. This paper investigates the intersection of m-learning, mobile social media, mobile apps, and crisis informatics in times of emergencies and disasters, using the recent Gipplsand earthquake in south-eastern Australia as an exemplar. It also discusses proactive preparation for educational resilience during emergencies and disasters.

Keywords: m-learning; mobile social media; mobile applications (apps); crisis informatics; crises; disasters; emergencies; earthquakes; educational resilience; power supply

Introduction

It was the evening of Tuesday 19th June 2012 and writing was underway for an ASCILITE 2012 paper on the topic of m-learning, mobile social media, crisis informatics, and formal and informal learning in times of emergencies and disasters. At 8.53pm, Australian Eastern Standard Time (AEST), the Gippsland region of south-eastern Victoria, Australia, was rocked by what was reported to be the largest Victorian earthquake in over a century (Caldwell, 2012). At a shallow depth of 9.9 km, the earthquake registered 5.4 magnitude on the Richter scale (USGS, 2012). The epicenter of the earthquake was at -38.304 latitude and 146.200 longitude (Geoscience Australia, 2012), southeast of the township of Moe where Monash University's Department of Rural and Indigenous Health (MUDRIH) is situated. The earthquake was felt throughout the Gipplsand region. Monash University's regional Gippsland Campus is located a thirty minute drive down the road in the township of Churchill, and a number of centres belonging to Monash University's School of Rural Health are dotted throughout the region, including sites at the various district hospitals. As such, the earthquake affected students, and academic and general staff living in the area.

While no fatalities were recorded, the earthquake caused damage. Within some of the institution's departments, such as MUDRIH, plaster had fallen from ceilings, cracks were reported to have appeared in the staff accommodation centre's walls, and my office was a sea of shattered glass brought about by document frames falling from various heights, with books and other items being tossed from their positions on a bookshelf. Yet this was but a mild inconvenience compared to what our Christchurch colleagues had endured in their 2011 earthquake.

As the Gippsland earthquake struck at night, daily academic activities were not severely disrupted, even though some staff experienced disruption of workflows in the aftermath and cleanup. However, had staff or students been at their desks at the time that it struck or had the power failed during or after the event, there was the potential for the earthquake to cause greater challenges, including affecting the continuance of online courses. For example, the Gippsland region produces 80% of Victoria's power supplies. One of the region's electricity producers – the Yallourn Power Station – which was already operating at a reduced capacity at the time due to the flooding of the adjacent open cut coal mine from the Yallourn River, had one of its two remaining units 'tripped' as the result of the earthquake (Levy & Partenza, 2012). Had the earthquake struck during a peak use period, the state's power stability may have been seriously affected. Additionally, some forms of telecommunications experienced challenges during the event. Phone lines were jammed, key websites crashed due to the high volume of traffic at the time, and formal media channels lagged in providing key information to locals.

However, social media went into hyperdrive, providing a means of connectivity, crisis informatics and learning opportunities during and after the emergency event. Hagar (2010, p. 10) first coined the term crisis informatics to describe "the interconnectedness of people, organizations, information, and technology during crises". As

Palen, et al. (2010) note, citizens are naturally information-seeking and will principally rely on their social networks for information, interpretation, and guidance, during emergencies and disasters. The Channel 10 Late News reported on the day that tweets about the earthquake occurred within seconds of the earthquake commencing, and the event was the top trending topic on *Twitter* Australia-wide (Channel 10 Australia, 2012). *YouTube* also provided a means for affected individuals to upload their videos. On *Facebook*, conversations commenced with the anticipated "I felt the earth move under my feet". Factual information and safety warnings were provided through this conduit, including the embedding of hyperlinks to websites which contained up-to-date information. This was crucial in helping to quell community concern as key websites such as Geoscience Australia had crashed under the volume of traffic from concerned citizens wanting information (Levy & Partenza, 2012). Social networks were also used to provide light-hearted responses to the situation. One comical offering on *Facebook* was the posting of a photograph of collapsed shelving and extensively damaged merchandise in the supermarket 'Not Quite Right' (NQR) in the nearby township of Morwell, with the accompanying slogan: "There's something not quite right about Not Quite Right". In addition to this image going 'viral' as it was shared around the social network, the image was later picked up by the mainstream broadcast media as a visual icon of the damage from the Gippsland earthquake for its news broadcasts (ABC, 2012). Similar experiences of the key role that social media has played in times of crises have been noted by others (see Sutton, Palen & Shklovski, 2008; Willems, 2011).

How can the events of the recent Gippsland earthquake serve as a catalyst to safeguard learning and teaching for the future? This paper contributes to the theme of sustainable futures of learning and teaching in a climate of change. It explores m-learning, mobile social media and crisis informatics in times of emergencies and disasters in the backdrop of the Gippsland earthquake. It also discusses proactive preparation for educational resilience during emergencies and disasters.

Emergencies and disasters

Earthquakes are a phenomenon not usually associated with the Australian continent, yet they occur nonetheless. Historically, the strongest earthquake recorded onshore was the April 1941 Meeberrie earthquake in Western Australia which registered 7.3 magnitude on the Richter Scale. However, the December 1989 Newcastle earthquake in New South Wales, registering 5.6 magnitude, is considered to be Australia's most significant earthquake due to the associated loss of human life and the costs of damages (Seismicity in Australia, 2011).

Earthquakes are but one example of a crisis event. Crises can occur anywhere, anytime, and can affect academia in minor or major ways, from the safety of staff and students, through to disruptions of teaching and learning activities. In Australia, the term crisis is operationalised to incorporate events which result from human action or inaction, and/or due to as acts of nature such as fires, storms, floods, and cyclones (DBCDE, 2011). In addition to the type of event, the term crisis also encompasses the scale of the event. The scale of the event can be situated on a 'continuum of magnitude' (Oliver, 2010). Emergencies fall at the lower end of the spectrum as they are considered as having localised impact only. Emergencies fall in the middle of the continuum of magnitude as the resultant human, material, economic, and/or environmental losses exceed the ability of the affected community to cope in the situation (European Commission, 2008). Catastrophes have the highest magnitude of scale, with the organisational, community, and societal impact of catastrophes extending far beyond its geographical locality (UNISDR, 2009).

Future of learning in a climate of change

Hagar (2010, p. 12) notes that "the world will face far more crises and we need to be prepared for a variety of scenarios". This involves not only ensuring the physical safety of students and staff within academia, but also the continuance of academic activities. To safeguard the sustainable future of learning and teaching activities in a climate of change, crises need to be anticipated and strategically planned for in order to optimize seamless operations in a range of scenarios. For example, Kensington, Daellenbach & Davies (2012) shared their challenges in enabling the continuance of formal learning following the Christchurch earthquake in February 2011.

Online operations may be a possibility for both on-campus and off-campus students under such circumstances. However, Agnew & Hickson (2012) note that while there is a body of literature concerning delivery of formal learning in online environments during crises, they identify the paucity of literature in and around "moving to online assessment in a semester disrupted at short notice by a natural disaster" (p. 2). Thus both learning and assessment must be considerations in times of crisis. Further, as was potentially the case in the recent Gippsland earthquake, power instability can threaten any online learning that is mains-power reliant. What might the solution be?

Mobile everything

The use of handheld mobile devices for learning during disasters and emergencies, especially when these occur in and around learning institutions, may be a solution. This is especially the case as mobile devices are portable and affordable telecommunications owned by most citizens. As Educause (2010, p. 3) has noted, “handheld technology can not only accompany the learner almost anywhere but also provide a platform that is rapidly evolving and always connected to data sources”. Mobile phones are also not totally reliant on mains power supply. Although they have their own battery limitations, the addition of solar chargers or portable wind-up chargers (which connect to the phone via USB) are an essential part of any potential emergency kit when mobile technology is a consideration in times of crisis.

Apps

Learning for the future involves considerations on what educational technologies lie on the horizon. The annual Horizon Report (Johnson, Adams & Cummins, 2012) by the New Media Consortium comments on educational technologies in a ‘time-to adoption’ framework of less than or equal to one year, two to three years, and four to five years. While mobile learning has already been adopted (Johnson, Smith, Willis, Levine, & Haywood, 2011); mobile applications (‘apps’) are the new frontier for the immediate future. Apps are computing software for specific purposes such as mobile phones. Saylor (2012) refers to the Internet-connected smartphones as ‘app-phones’ and suggests that these mobile devices should be considered foremost as computing devices before they are considered as telephones.

According to the Horizon Report 2012 (Johnson et al., 2012, p. 6), apps for mobile devices “are the fastest growing dimension of the mobile space in higher education right now”. Apps however, need not be designed specifically for learning purposes in order to be used in formal learning opportunities. Educause (2010, p. 1) notes that “The software that underlies m-learning includes not only mobile applications designed specifically for learning purposes, but also those designed for other uses – such as geolocation, data access, readers, and maps – but that can be adapted for educational purposes”. Thus in relation proactive preparation for educational resilience during emergencies and disasters, mobile apps may be useful for providing seamless formal learning purposes including assessment, providing social media connectivity, and providing software to pertinent for personal safety.

In relation to the provision of seamless formal learning opportunities, purpose-built institutional apps enable access to key features of the institution’s website and learning management system (LMS). For example, the Monash University smartphone app (Monash University, 2012) enables access to such key features as email and units. Moreover, the Monash app has the Monash University maps integrated with Google Maps so that the user can not only locate themselves onsite, but also track movements towards other destinations on (or off) campus. During emergencies and disasters, this particular feature could be used as a safety device in times of power-failures or overcome potential location disorientation due to smoke inundation.

In relation to apps to enable mobile social media, such as the *Facebook* app, one tap on the smartphone icon can allow direct access to a spatially-condensed version of the Internet website. Such social networks can provide immediate responses by others in the social network including the provision of crisis informatics and detailed localised information that may not be available on main channel information sources.

Specifically in relation to smartphone apps to assist personal safety of students and academic and general staff during crises, there are a number of free and/or cheap apps which may be beneficial:

- emergency location beacon app which utilises the global positioning system (GPS) of smartphones, such as the ‘Rescue Me’ app (Edith Cowan University, 2012);
- flashlight app which is handy when power fails as it often does in emergency and disaster events;
- seismometer apps which utilise the in-built vibration sensors of the use of the smartphone; and
- cardio-pulmonary resuscitation (CPR) apps which is useful for emergency first aid including cardiac compression rates through an audio beep for adults and children.

While this list is not conclusive, it serves to prompt proactive thought over what are the essential emergency needs during, and in the resolution period after, emergencies and disasters, not simply for teaching and learning, but also for the safekeeping of students and staff during crises.

Conclusion

Emergencies and disasters are increasingly frequent scenarios. These are events which affect students and staff alike, and may disrupt teaching, learning and assessment activities. The Gippsland earthquake struck without warning, as do many emergency and disaster events. How can staff and students be prepared for such events? How can teaching, learning and assessment be sustained in a climate of change? How can educational resilience be assured when infrastructure is disrupted or jeopardised?

This paper has discussed m-learning, apps, crisis informatics and mobile social media as means to help support educational resilience both during the crisis event and in the post-crisis timeframe. Through such hardware and software, potential strategies for seamless teaching, learning and assessment may be offered. This strategy will be the basis for further research.

Online training: Sustainability in the face of the unskilled, unsupervised, unmotivated “long tail”

Communities of discourse and market places often follow power laws with “long tailed” distributions. The present student “voucher” system and uncapped demand in higher education leads to an analogous “long tail” in the tertiary sector. We argue that student attrition in the “long tail” is part of a natural democratic process of “churn” - legitimate peripheral participation which leads some students to the realisation that they are not sufficiently motivated or prepared for fuller participation in the academic community. We illustrate this idea with data from a task in an introductory psychology program to examine the relationship between persistence, performance, motivation and demographics. We found distinct subgroups whose performance is defined by levels of conscientiousness/motivation and initial skill. We suggest that it may be counterproductive to retain students who perform poorly or are disengaged. However, we also identified different patterns of performance and suggest that attrition can be attenuated by targeted interventions to improve initial performance of identified groups.

Keywords: online learning, long tail, motivation, mastery

Introduction

The long tail

Online social networks generate unequal distributions of audience in the face of broad availability and choice
Shirky (2008) in an influential blog entry entitled “Power laws, weblogs and inequality”, argues that internet blog audiences follow a power law rather than a normal distribution, leaving a “long tail” of blogs with low readership, due to the nature of social networks rather than the intrinsic quality of these blogs. More popular blogs by definition have more incoming links as a direct function of their popularity, and thus will become even more popular. While the internet provides a vast potential readership for online material, blogs and websites that are already popular will have a greater influence in terms of determining what else their readers engage with. Although it is possible for new blogs to make an impact in the marketplace, it will be more difficult, and irrespective of quality, there will be a good deal of churn in new blog generation and new audience due to the nature of power laws that operate within social networks. This paper argues that the student “voucher” system and uncapped demand in higher education leads to an analogous “long tail” in burgeoning student enrolments and proliferation of courses in the tertiary education sector.

Non-traditional pathways to higher education, freedom of choice and uncapped student demand generates a “long tail”
The recent Bradley review of higher education (Bradley, Noonan, Nugent, & Scales, 2008) led to a student-centered funding model which has created an ongoing challenge for smaller universities to retain student numbers in the face of uncapped places available to students at “better” universities. Many universities are forced to dip lower into the entry score pool or actively pursue non-traditional student markets to maintain their student numbers and the funding attached to teaching load. This student “voucher” system and uncapped demand strives to uphold egalitarian principles, democratising choice of higher education in the same way the

internet democratises blog readership. This leads to a "long tail" both in terms of student enrolments and the popularity of tertiary institutions, courses, and modes of study.

Online cohorts
Online students play an increasingly important role in maintaining student numbers at some institutions, but there are important lessons to be learnt from teaching online students: many are under-prepared for tertiary studies and have difficulty completing tasks without real-time supervision, creating a "long tail" in the distribution of academic performance. Over several years of teaching online cohorts of psychology students, it has been noted that there is a very high dropout rate of first year students (approximately 40% of online students enrolled in the introductory unit of psychology withdraw from the unit or do not attempt all the assessments), whereas dropout rates in later stage online units are the roughly equivalent to rates for equivalent on-campus units. These online units have no entry requirements and many of the students who drop out appear to do so because tertiary study was not what they expected either in terms of the academic content, or in terms of the skill level and time required to engage appropriately with the learning material. Although we have used a range of teaching interventions to try to retain our students (Fleckhammer & Wise, 2010, 2011, 2012), it may be that high churn and attrition are perfectly acceptable as we move away from traditional student intakes to less well-prepared cohorts with long tails. If we understand student attrition from introductory units in the context of providing the opportunity to try something unfamiliar, the *availability of choice* is of primary importance, *not* the retention or attrition of the student. However, when the student progresses beyond first year units of study *then* retention becomes a critical focus as both student and institution have made a significant investment in the shared learning venture - the long tail has been trimmed. If on-campus student numbers in smaller universities are maintained by dipping lower into the tertiary entry pool and seeking students from non-traditional pathways, we may start seeing a much longer tail in these cohorts as well. While student attrition from on-campus study has been seen as a pressing problem in the past, is this way of thinking still appropriate in the context of the long tail?

Current study

This paper argues that student attrition in the "long tail" of enrolments is part of a natural democratic process of "churn" in which legitimate peripheral participation in a community of practice (tertiary studies) leads many students to the realisation that they are underprepared for, or uninterested in, fuller participation in this community. The question we are raising is *should* we aim to retain the "long tail" of poorly performing students? Is attrition *within the tail* a natural and appropriate form of selection for cohorts increasingly made up of students from beyond the traditional school-based entry pathways? In considering this question, we are aiming to understand specific patterns of performance that might call for specific interventions. For example, students performing poorly through lack of specific skills might benefit from learning interventions targeting those skills, whereas students performing poorly through lack of sufficient academic challenge would benefit from different interventions. Students performing poorly through lack of interest in learning (for whatever reason) might be allowed to drop out until they are sufficiently motivated to return. We use data from an experimental task in an undergraduate introductory psychology program as a micro-study of this idea, examining the relationship between persistence, performance, and demographics on a task which students should be motivated to complete.

The data set comes from an experimental study aimed at testing the efficacy of a brief (90 minutes) unsupervised web-based training package for learning scanning of aircraft instruments. The data was collected from the first year cohort who had to write the assignment, Preliminary data presented at last year's Ascilite conference suggested that unsupervised psychology students can readily learn the instrument scanning task, but we noted a surprisingly low participation rate and high dropout rate during the course of the experiment, despite the fact that the data students were providing the basis of their major assignment. This paper presents a more detailed analysis of a larger data set, and focuses specifically on performance characteristics and demographic details of students who did, and did not, complete the task. We examined whether (poor) performance predicted dropout from the study, and whether students who performed poorly in early stages of the experiment but persisted with the entire task improved their performance by the end. That is, what is the nature of the tail? Who are we teaching and how does this inform pedagogy?

Method

Participants

Participants were recruited from a pool of about 600 university students enrolled in a first year psychology program who were invited to participate in an experiment to collect data for their major assignment, a research report on perceptual learning.

Materials

The instrument scanning task was based on a task described by Kellman and Kaiser (1994) and was web-delivered using Inquisit software (by Milisecond.com). The main stimuli comprised a prototype of a standard 6 instrument panel (see Figure 1, left panel). Participants were also asked to complete a questionnaire providing brief demographic information and information on previous flying experience, gaming experience, and self-reported level of hand-eye coordination.

Figure 1: Experimental stimuli. Left panel shows the six main instruments (simulated) of Cessna cockpit used as stimuli in all experimental blocks except the "transfer" block. The instrument configuration indicates a "straight and level" situation. Right panel shows the instrument variation used in the transfer task. This configuration indicates a climbing left turn.

Procedure

After obtaining informed consent, participants were given a brief description of the study, and a sequence of training pages describing the function of each instrument of the instrument panel. They were then given a series of 30 instrument clusters depicting specific aircraft situations. Nine aircraft situations were depicted in the experiment including: *1- Straight and Level* (e.g., see Figure 1 left panel), *2- Level Climb*, *3 - Level Descent*, *4 - Level Left Turn*, *5 - Level Right Turn*, *6 - Climbing Left Turn*, *7 - Climbing Right Turn*, *8 - Descending Left Turn*, and *9 - Descending Right Turn*. An additional *10 – Incongruent condition* was also included, where one of the instruments was inconsistent with the other five instruments in the display. As soon as the participant identified the aircraft situation they were asked to press the spacebar. They were then presented with a list of the 10 options to describe the aircraft situation. The time to make each response was recorded.

After completing the 30 trial *Practice block*, participants were presented with a sequence of 90 instruments clusters (*Training block*) and were asked to identify the aircraft situation as rapidly as possible. To ensure that participants were not just guessing based on using the artificial horizon, we developed *Masked Instruments block* and *Integrated Instruments block* that exposed participants to the relationship between the artificial horizon and each other instrument and to relationships among instruments other than the artificial horizon respectively. These two tasks aimed to promote more rapid and effective information extraction using all the instruments via training tasks that were not directly related to actual tasks in the flying domain and are described in more detail in McLean, Wise, and Williams (2011). After each of the Masked and Integrated Instrument sequences participants completed a block of standard trials (*Test 1 block* and *Test 2 block*, respectively) to track performance at identifying the aircraft situation. To test the perceptual versus cognitive nature of the learning achieved, participants were finally tested on a set of instrument panel clusters in which the nature of the instruments and their interaction remained consistent with previous training, however the overall position and look of the instrument panel changed substantially (*Transfer block*) as shown in Figure 1 (right panel). Finally, the participants completed the demographic survey. The whole experimental sequence for each participant required approximately 90 minutes to complete.

Participants were asked to devote their full attention to the task, and work in a quiet, distraction-free environment. The use of web-based delivery in relatively uncontrolled circumstances mimics the conditions under which web-based and mobile training operates, such that each participant sets the parameters of their own working environment. The paper presents analysis of completion rates and patterns of performance for those who did not complete the task; data on accuracy and speed of performance, and patterns of performance that may be indicative of different levels of motivation with the aim of understanding attrition rates and potential learning interventions. The analysis of data to evaluate the potential of web-delivered instrument scanning tasks as portable learning modules for aviation training is addressed elsewhere (e.g., McLean et al, 2011; McLean, Wise, & Williams, 2012 this volume).

Results and discussion

Completion rates

Results for completion rates
There were 387 distinct sets of responses from a potential pool of around 600 respondents. Only 97 contain the full set of 510 trials. Of the incomplete data sets, 140 were deliberately aborted by the participant using a special quit command. Some of these were instructors demonstrating the system, but the majority were participants looking at the program but choosing not to complete the data collection (this was inferred from special commands by users to skip to specific stimuli without collecting data). The remaining 150 incomplete sets were terminated simply by closing the web browser. The relationship between response patterns and completion rates was examined by partitioning the cohort into three groups: i) those who dropped out during or at the completion the practice block, ii) those who completed the practice block, but did not complete the whole experiment, and iii) those who completed the whole experiment.

Table 1: Trials completed, valid keystrokes, and response accuracy for participants who dropped out at different phases of the experimental task

Group	Mean # trials completed	Median # trials completed	Mean % Invalid Keys	Median % Invalid Keys	Mean % correct	Median % correct
Dropped out in Practice block	8.68 (7.49)	7.00 (9)	18.28 (27.97)	5.56 (25.00)	60.65 (32.90)	62.50 (60.00)
Dropped out after Practice	169.04 (128.92)	140.00 (163)	5.65 (15.95)	0 (2.7)	59.90 (26.93)	65.12 (40.00)
Completed whole task	510 (-)	510 (0)	0.87 (6.63)	0 (0)	75.81 (20.27)	83.53 (26.00)

Note. Parentheses show SD for means and interquartile range for medians

Table 1 shows that those who dropped out in the first block completed very few trials and made many invalid keystrokes, that is pressing keys *irrelevant* to the task not just an incorrect response option. Those who dropped out after the first block progressed about a third of the way through the task, but had a significant number of invalid keypresses. The proportion of correct responses was markedly higher for the completers, but did not differ for those who dropped out in or after the first block. Six participants had more than 2.5% invalid responses, most of which turned out to be due to the numlock key being set to the incorrect state. We excluded from further analysis in case the incorrect (and thus uninformative) feedback they would have received adversely impacted their performance. This left 93 complete cases, 91 of which had zero invalid keypresses.

Discussion of completion rates
These data suggest that most of those who did not complete the task did not learn the task adequately. Moreover, many of those who did not show adequate performance on the task within the first block but persisted with the experimental task did not improve their performance in later blocks of trials. That is to say, failure to learn the task to a high level in the early stages decreased motivation to continue. In the light of these data, it is important to understand performance patterns of students who drop out of their studies in terms of capability and motivation. Reducing attrition from a long tail of poor performance may serve merely to increase the rate of poor performance. Preliminary data from an ongoing study comparing supervised and unsupervised training environments supports this conclusion. Anecdotal evidence from supervisors supports the idea that the presence (but non-intervention) of a supervisor for students undertaking web-based experimental tasks improves completion rates but decreases the overall quality of data by retaining more students who are performing poorly as a result of obvious lack of engagement or due to lack of task-related skill. The motivation for participation (e.g., slavish completion while being watched, reward for completion of the task, reward for performance on the task, compared with intrinsic interest in the task itself) may promote different patterns of performance, different patterns of engagement and different types of interventions to improve task performance.

Screening of data prior to analysis of response time and accuracy

Preliminary screening for outliers

Means, standard deviations (SDs), medians and ranges for response time and accuracy were computed for each aircraft situation within each block. Many such block/situation combinations contained substantial outliers – for example, while the mean response time was around 10 seconds for the first block and 4 seconds for the last, there were trials lasting over a minute. This is good evidence of data being corrupted by "coffee breaks" despite the fact that participants were measuring response times and accuracy for their own major assignment! The long tail and small numbers in some crossings made it difficult to determine whether a response time of, for example 15 seconds, was an error or simply a very slow response. Similarly, there were response times of only a few tens of milliseconds which cannot be meaningful in terms of the experimental task. Removing trials based on SDs was not practical since the SDs were heavily inflated by the outliers we were trying to identify. We tested a number of different screening methods before adopting the commonly used 5% trim, removing the top and bottom 2.5% of the entire distribution before calculating any other statistics.

Further screening of outliers

Even after the preliminary screening described above, there was quite considerable variation in performance. Responses ranged from 0% correct to 100% correct in nearly every block. The average correlation of the percent correct responses across all possible (21) block pairings was .72. The lowest correlation was .46 (between the first Practice and final Transfer block – those most temporally separated), the highest was .9 (between the Test1 and Test 2 blocks – the two most similar blocks). While these correlations indicate a high level of overall performance consistency, error rates varied markedly for some individuals. Deciding whether to exclude cases based on performance is an important issue in understanding learning and performance. By design, chance performance is ~10% for the standard blocks. Every standard block had a least one case that scored 0% correct, however, the lowest scoring individual was different in each block. There seemed to be "good performers" who scored more than 50% correct on most blocks but had a "bad" block, the location of which was not predictable. Six participants stood out as aberrant cases – performing acceptably in the practice block but declining to chance or near chance levels in the remainder of the experiment - and were removed from further analysis. All 87 remaining cases were retained for further analysis.

Discussion of deletion of cases

While the 6 extreme/atypical cases were removed from the analysis to prevent bias, it must be noted that these represent real performance of participants who completed the task. We do not know their situation or motivation, but we must acknowledge that they made several hundred deliberate keypresses. We must conclude that a small percentage of participants are simply going "through the motions" (e.g., a participant with some previous flying experience scored 77% correct on practice trials but responded at chance levels for the remaining trials) learning nothing from the task. This could be put down to motivation, distraction, or difficulty using the interface. This may also be remedied by providing different kinds of incentives, feedback, or supervision the training as will be discussed below.

Accuracy and speed

Results and discussion of accuracy

As can be seen from Table 2, mean accuracy was highest in the Practice block, dropped slightly during the training block then stabilized in the two test blocks at a level comparable to the Practice block. Accuracy also dropped from the Test 2 to the Transfer block – the performance level (and size of drop) was almost identical to the drop observed in the Training block. A repeated measures ANOVA indicated that accuracy varied significantly across blocks ($F(4, 83) = 12.30$, $p < .001$ – note that to stabilize variance and avoid overdispersion problems the arcsine transform was applied to accuracy scores before conducting the ANOVA). Four contrasts comparing successive blocks showed that, apart from the two test blocks, accuracy on every successive block was statistically different from that on the previous block – that is accuracy increased at each block except for the transfer block. This indicates that genuine learning is occurring, but an analysis of the learning rates is not the focus of this paper. The medians tell a slightly different story. The overall median accuracy is markedly higher than the mean accuracy for all blocks. Median accuracy peaks in the Test 2 block rather than the Practice block. It falls in both the Training and Transfer blocks, but the fall in absolute size is not as large as that observed for means. This mean/median discrepancy is consistent with a strong skew. This is confirmed by a large negative skew statistic for the distribution of each block in conjunction with positive kurtosis. This indicates a fairly tightly packed distribution of good performances and a long tail of poor performances.

Table 2: Aggregate accuracy (mean percent correct responses) across standard experimental blocks

	Practice Block	Training Block	Test 1 Block	Test 2 Block	Transfer Block
Mean (SD)	82 (17)	76 (18)	81 (23)	81 (20)	75 (23)
Median (Min/Max)	87 (10/100)	81 (11/100)	91 (8/100)	89 (8/100)	83 (100/100)
Skewness/Kurtosis	-2.36/6.44	-1.27/1.91	-1.85/2.67	-1.78/2.93	-1.15/.59

N=87

Results and discussion of response times

The overall pattern of response time data is shown in Table 3. Means and medians are comparable indicating that response time is less dependent on a person's place in the overall distribution. The distribution is still slightly negatively skewed, but less so than proportion correct. Mean response times begin at just under 7.5 seconds and steadily decrease to just under 4.5 seconds by Test 2 block indicating an overall 40% improvement in speed. A repeated measures ANOVA indicated that mean response time differed significantly across blocks ($F(4, 83) = 85.67$, $p < .001$). A set of four contrasts comparing successive blocks showed that responses got progressively quicker across each block, except for the transfer block where, as expected, responses were slightly, but significantly slower than the Test 2 block (all contrast p's < .001).

Table 3: Aggregate data for time to identify the aircraft situation in standard blocks and to identify congruent versus incongruent in Masked and Integrated Instrument blocks

	Practice	Training	Test 1	Test2	Transfer
Mean (SD)	7399 (2819)	5374 (1938)	4219 (1707)	3585 (1456)	4440 (2021)
Mean of Individual SDs	3123	2186	1718	1514	2311
Median (Range - Min/ Max)	7382 (799/13872)	5523 (493/9752)	4296 (498/8281)	3742 (332/6739)	4678 (428/8818)
Skewness/Kurtosis	-.08/-.49	-.56/.57	-.43/.27	-.48/.03	-.24/-.36

N=87

The SDs also steadily decrease, indicating more consistency *between* participants. As with error rate, performance is worse on the Transfer task – the mean response time for the Transfer block is halfway between the Training and Test 1 block. SDs also increased in this block, indicating a wider variation in the participants' ability to transfer training to the different display. Table 3 also shows the Mean SDs of individuals' time to identify the stimulus– that is how much an individual participant's performance varied within a block. Intra-individual variability on response time declined steadily over successive the blocks to around half its initial size. Response time variability increased in the transfer block similar to the increase in mean response time, such that the value was similar to that observed in the Training block.

Aggregate scores – aircraft situation and demographic data

Results and discussion of analysis by situation type as a function of demographic data

Responses were collapsed over blocks and aggregated by situation type. Across the aggregate data, accuracy, and response times tell similar story. In every block "straight and level" was the most quickly and accurately identified situation. Straight climb and descent were slightly less accurate and somewhat slower, while turns were slower and less accurate again. The instrument conflict situation had the second fastest response time but the lowest accuracy. For the purposes of this paper, we are less interested in the aviation-related aspects of identifying aircraft situations than patterns of responses that distinguish between different levels of learning or different levels of motivation to engage with the training task. Of specific interest for this paper is the idea that different patterns of results may correlate with different demographic factors, which in turn might lead to targeted interventions to improve learning.

Cluster analysis of – different patterns of responding evidence different learning strategies

Method

To empirically assess our intuitive hypothesis that there are literally different *types* of learners in this cohort we conducted a cluster analysis on the speed and accuracy data aggregated across situations within blocks. Since speed and accuracy measures had different scales, each variable was standardised before analysis. SPSS V20 hierarchical agglomerative clustering algorithm was used, with Euclidean distance as the distance measure and Ward's method (which minimises the within cluster variance thus favouring homogeneous clusters) used as the linking function. Other distance and linking functions were also examined, and yielded results consistent with those described below.

Results and discussion of cluster analysis

The dendrogram showed two widely separated clusters, the larger of which had about seven times as many members as the smaller. The dendrogram also indicated that the larger cluster could be split cleanly into two near equal sized groups, the larger of which also showed two subtly different subgroups. Two, three, and four cluster solutions were considered. The two, three, and four cluster solutions paint a similar picture, but the three and four cluster solutions provide some interesting insights into the microstructure of the larger group. Two and four cluster solutions are presented, with the four cluster solution discussed in detail. Figure 2 provides a visual depiction of the structure of this data tagged with a summary of the make-up of each cluster, which are described in detail below.

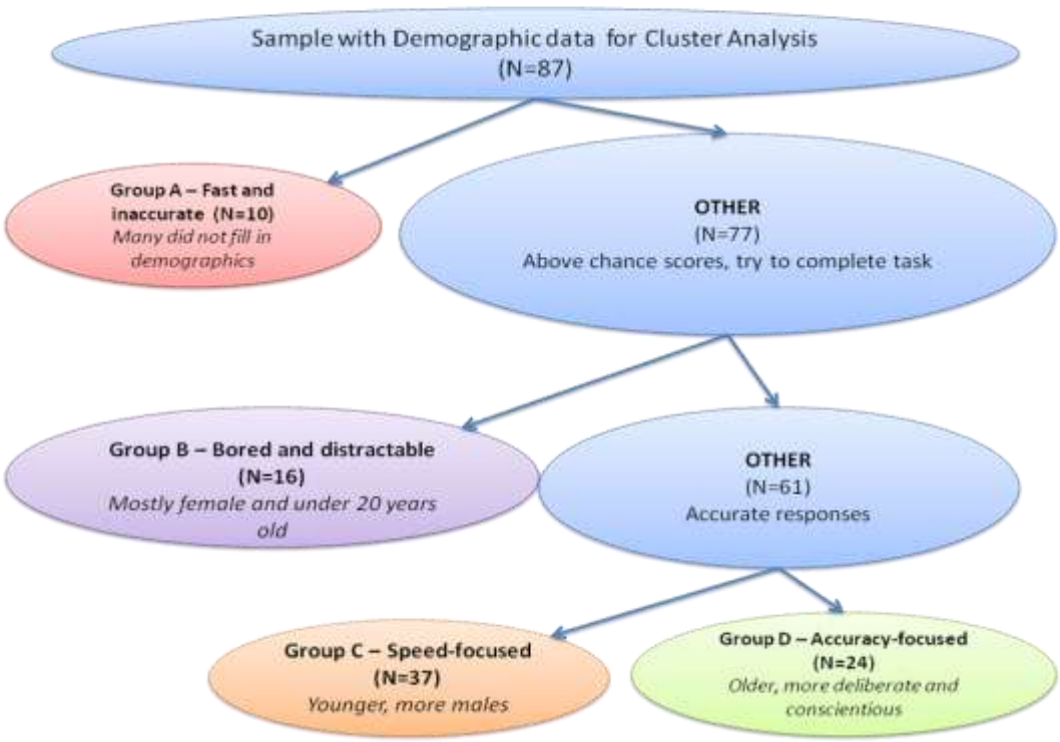

Figure 2: A visual depiction of the cluster analysis results with summaries of the demographic characteristics of each cluster.

Table 4: Two and four cluster solutions for speed and accuracy (see text for further description).

Group	Practice	Training	Test 1	Test 2	Transfer
RESPONSE TIMES (MILLISECONDS)					
A, N=10	4620	1680	783	806	1293
Other	7759	5853	4665	3946	4848
Which splits into					
B, N = 16	8563	6119	4850	3436	3577
C, N=37	6458	4908	3887	3451	4338
D, N = 24	9230	7134	5742	5048	6482
ACCURACY (PERCENT CORRECT)					
A, N=10	62	45	28	44	43
Other	85	80	88	86	79
B, N = 16	74	65	71	64	52
C, N=37	87	86	93	93	85
D, N = 24	87	81	91	91	88

As Table 4 shows, the two cluster solution can be described straightforwardly. Group A has low overall accuracy, averaging around 44%. They show the fastest initial response times and the largest speed increase, the mean response time on the Test 2 being only 17% of the practice response time. They also show the least accurate performance. These people could be described as "fast and loose" or "going through the motions", but with some sense that they should complete the task, despite low engagement. The "other" group display consistently high accuracy, and from a slower start, an overall doubling in response speed by the end of the test block, suggesting that these participants are actually engaged with the task and learning something across trials. "Other" breaks into three smaller groups. Two (labeled C and D) are superficially similar - both show high accuracy which improve marginally over the course of the task, group D, however, is about 3% better on most blocks and distinguishes itself with an outstanding performance on the transfer block. The response time of both groups have almost halved by the second test block, although group D's response time is about 40% longer than that of group C. On this basis we might call group C "speed-focused" and group D "accuracy-focused." Group B is an interesting group which lies somewhere between group A and groups C and D. Their initial speed and accuracy lie between those of A and C, but over the course of the task their accuracy falls and their responses speed up. Having begun the task reasonably well, they appear to lose interest and then try to rush through the remainder of the task and pay a steep price in terms of accuracy. On this basis we might call this group the "bored, distractable" group.

We examined the demographic data of each cluster (see Table 5). Note that the demographic data was not used to perform the cluster analysis, so some significance can be attached to these comparisons. The most significant feature of group A is that they did not provide responses for more than half their demographic questions. This profile would seem consistent with our characterisation of their style as disengaged or uninterested. Group B is almost exclusively female and mostly under 20 years of age. The majority reported playing no computer games, using a computer for non-study purposes (such as using Facebook, downloading music, doing assignments) at least five hours a week and doing little or no sport. This profile is consistent with the typical first year psychology student and their performance likely reflects little intrinsic interest in the task, but a high level of perceived conscientiousness, slavishly "finishing" all assigned tasks in the unit, despite not actually engaging in the task in any meaningful way.

Table 5: Clusters as a function of demographic variables (see text for further description). Numbers show % of cluster having that level of each attribute.

		A fast and loose	B bored, distractible	C speed focused	D accuracy focused
Age	**Under 20**	40	38	46	38
	21 - 24	10	25	24	4
	25 - 30	0	6	16	12
	31 - 35	0	13	5	17
	36 - 50	0	6	7	21
	Not given	50	12	6	8
Gender	**Female**	40	94	65	63
	Male	10	0	27	29
	Not Given	50	6	8	8
Computer Games	**1-2 hours**	0	0	3	13
	3-5 hours	10	0	8	0
	< 1 hour	20	94	84	75
	Not given	70	6	5	12
Using a Computer	**< 1 hour**	0	6	8	4
	1-2 hours	0	31	27	29
	3-5 hours	30	50	35	17
	> 5 hours	0	6	24	42
	Not given	70	6	6	8
Sport	**< 1 hour**	10	56	51	4
	1-5 hours	10	25	24	29
	11-20 hours	0	0	6	9
	6-10 hours	10	6	14	50
	Not given	70	13	5	8

The profile of groups C and D was almost identical. The main point of difference is that group D had many more older persons in it (> 31), while group C was much younger (mostly < 25). Both groups were approximately two thirds females, one third males, over-represents males compared with the gender profile of the psychology cohort. The vast majority reported playing less than 1 hour of computer games a week (although the younger group C had a small percentage playing several hours a week). Both groups used a computer for non-gaming purposes several hours a week (group D slightly more) and both groups reported doing some exercise, although group C had a large number that did only a small amount, while half of group D reported doing 6-10 hours per week. These profiles would seem stereotype-consistent with the younger group being considerably faster and slightly less accurate, and the older group being very conscientious and deliberate. It is also important to note that given the age profile of the undergraduate cohort, the older group D is heavily over-represented in our results, again speaking to maturity and conscientiousness in terms of completing work – rather than just completing the task (checking boxes), these participants engaged with the task and completed it "properly". Interestingly, when we re-ran this analysis with the six cases we had previously excluded for very poor performance included, we obtained the same cluster solutions with five of the six cases joining the "fast and loose" group, further supporting our interpretation of this data.

Concluding remarks – attrition of the long tail

Participants who dropped out of the experiment appear to be the ones who did not "get" the task in the first place, or who could do the task easily but got bored. These two groups form the long tail, but for substantively different reasons. An important finding is that if there was insufficient learning in the Practice trials, there was not much improvement irrespective of persistence at the task, suggesting that repetitive drills are not useful if the basic drill is not understood. Perhaps these participants would have benefited from more conceptual training before attempting the actual trials, or perhaps they did not have the appropriate skills for the task. Those that got bored with the task might just need clearer incentives to boost their performance, in the form of external supervision or extrinsic reward for high scores. The cluster analysis allowed a compelling narrative in terms of the long tail of performance on the instrument scanning task experiment, but also generated a compelling narrative via the demographic data in terms of stereotypical student characteristics within the cohort. Rather than attrition being a problem, it may be a natural outcome of a long tail that recruits tertiary students from a pool of people for whom tertiary education is a relatively unknown quantity – something that seems socially desirable, but about which little is known. Equal opportunity to participate in higher education is a cornerstone of social justice, but in reality, tertiary academic study is not the panacea for a better society. Should we rethink student attrition in terms of a natural process by which students without the appropriate skill level or intrinsic motivation for tertiary studies should be encouraged to follow other pathways (for example vocational pathways through TAFE)? It may not benefit students or the institution to retain them in program of academic study for which they are not well-matched. Conversely, changing programs of study to try to capture disengaged students may not serve students or the institution either. Legitimate peripheral participation in a community of practice can motivate a strong desire to become a full member of the particular community, but can equally legitimately motivate a strong aversion to further participation in the community of practice (Lave & Wenger, 1991).

Mobile social media can be used to augment physical learning spaces and bridge formal and informal learning contexts. This paper presents the ongoing implementation and impact of a mobile social media project, which aims to augment and enhance a Product Design programme underpinned by a Design Thinking methodology. The goal of the project is to enhance student-learning experiences, positively impact their Design Thinking expertise development, and to explore the future of Design Thinking education enhanced by mobile social media. In addition it provides an opportunity for a small university department to engage with implementing and sustaining pedagogical change enabled by technology through the establishment of communities of practice. The paper describes the underlying Design Thinking and learning and teaching frameworks, the establishment of the community of practice, comments from lecturers, and the first pilot project with students.

Keywords: Mobile Social Media, Design Thinking, Product Design, Constructivism, Heutagogy

Introduction

The Product Design programme at AUT University was developed in 2007, launched with the first intake of students in 2008 and has been implemented over the following years. In 2012, the programme has 75 undergraduate students, and 10 students at postgraduate level. The Product Design programme is underpinned by a Design Thinking innovation methodology, which emphasises empathic, human-centred research, ideation, concept development and evaluation.

The development of a new academic programme provides many organisational and operational challenges. It also presents a unique opportunity to develop new approaches to learning and teaching without the constraints of institutional history and tradition to better respond to the needs of industry, the graduates and the wider community (Withell & Reay, 2011). To support and facilitate the teaching of Design Thinking methodologies, the Product Design programme was established around a collaborative physical studio experience. This provides an excellent environment in which lecturers work closely with students to enable them to construct knowledge and develop creative skills and processes. A review of literature has indicated that there has been very little research on Design Thinking education, specifically on how to develop Design Thinking expertise, learning and teaching approaches, models and learning and teaching environments.

A call for Learning and Teaching Development Fellowships (LTDF), funded by the University's central Centre for Learning And Teaching (CFLaT), provided an opportunity and catalyst for investigating the potential to augment the physical studio environment via mobile social media. The LTDF provides funding for time release and dissemination of practice-based research. Previous research indicated that lecturer professional development is a key factor in successfully implementing and sustaining pedagogical change enabled by technology. In addition a Learning And Teaching Enabled by Technology (LATENT) grant provided funds for supplying mobile devices for the department lecturers.

The key aims of the project are:

- To develop staff and student capability in social media for Design Thinking education;
- To enhance staff and student experience, and to positively impact the students Design Thinking expertise development; and
- To implementing and sustain pedagogical change enabled by mobile technology.

Design Thinking and Mobile Social Media

The term Design Thinking describes a human-centred methodology for innovation, which has evolved from the study of the unique ways in which designers 'think', and 'practice' (Bauer & Eagen, 2008; Leavy, 2010; Martin, 2009). Research on Design Thinking includes the study of how designers approach and solve problems, the methods and processes they utilise, their styles (modes) of thinking, their knowledge, their skills, their attitudes and their values. In addition the principles of Design Thinking include the development of meta-cognitive skills; problem solving; collaboration; reflective practice; and multiple, alternative perspectives. Design Thinking is increasingly becoming recognised and utilised by range of design areas, as well as other disciplines including engineering, business, management, information technology (IT), and education. Reflecting the recognition of Design Thinking methodologies as a fundamental core for design, and the uptake of Design Thinking across a range of disciplines, many international educational institutions are incorporating the teaching of Design Thinking into curriculum and programmes.

Design Thinking is based on an iterative process that includes key stages from research, insight development, creative exploration and development through to the evaluation and testing of ideas and concepts. During the implementation of the Product Design programme at AUT, careful consideration was given to the development of excellent physical studio spaces, as essential to developing a programme culture supporting Design Thinking. Each year group is allocated a large, open plan studio space, with individual students provided with well-equipped personal workspaces (see figure 1). The programme encourages students to work as much as possible in the studio spaces, and to create an environment that is supportive while creating an atmosphere of positive critical reflection on design decisions and processes. To facilitate this students are encouraged to display their design process work, prototypes and display models throughout the design process.

While great physical studio spaces provide an excellent environment to support the formal learning and teaching of Design Thinking in such areas as group collaboration, brainstorming, drawing/ideation and 3D prototyping, studios have a danger of 'insulating' students from real-world contexts. In contrast, Design Thinking methodologies require human-centred observation, interviews and the testing of ideas and concepts in 'real-world situations. Design Thinking also requires students to collaborate, share and to reflect about their works 'on-the-fly', while mobile, and in less formal learning situations. The use of mobile social media, mobile phones and tablets, blogs, twitter and other social media tools has the potential to complement, augment and enhance great physical learning environments by providing the tools and mechanisms that encourage students to take their learning outside into the 'real world', and to work more collaboratively in new and effective ways. In essence this approach bridges the formal and informal learning contexts for Design Thinking.

Figure 1: Physical Design Thinking Studio at AUT

Pedagogical Change

The use of mobile social media to augment a physical design studio paradigm creates an ontological shift in the understanding of their roles in teaching and learning of both the lecturers and of the students. This includes not only how the physical learning space can be richly augmented, but also to enable and facilitate student-generated content and student-generated learning contexts. Chi and Hausmann (2003) describe an ontological shift as “the re-assignment or re-categorizing of an instance from one ontological category to another" (p432). This can then result in a move along what Luckin et al., (2010) describe as the Pedagogy-Andragogy-Heutagogy (PAH) continuum from Andragogy (student-centred learning) towards Heutagogy (student-directed learning), as lecturers and students collaboratively redesign learning activities and assessments (Brown, 2006).

Augmenting the Design Thinking Studio Project

In response to the key opportunities identified, the Augmenting the Design Thinking Studio was developed. The project uses a participatory action research methodology (Swantz, 2008) in which the project, and methods utilised evolve through the duration of the project in response to emerging issues and findings. A project framework was developed (see figure 2) to guide key components of the project. These include:

1. Developing staff and student capability through communities of practice (mobile devices and social media).
2. Reinventing learning and teaching processes, bridging the physical and virtual.
3. Developing Design Thinking online resources.
4. Developing ‘smart’ feedback and assessment tools.

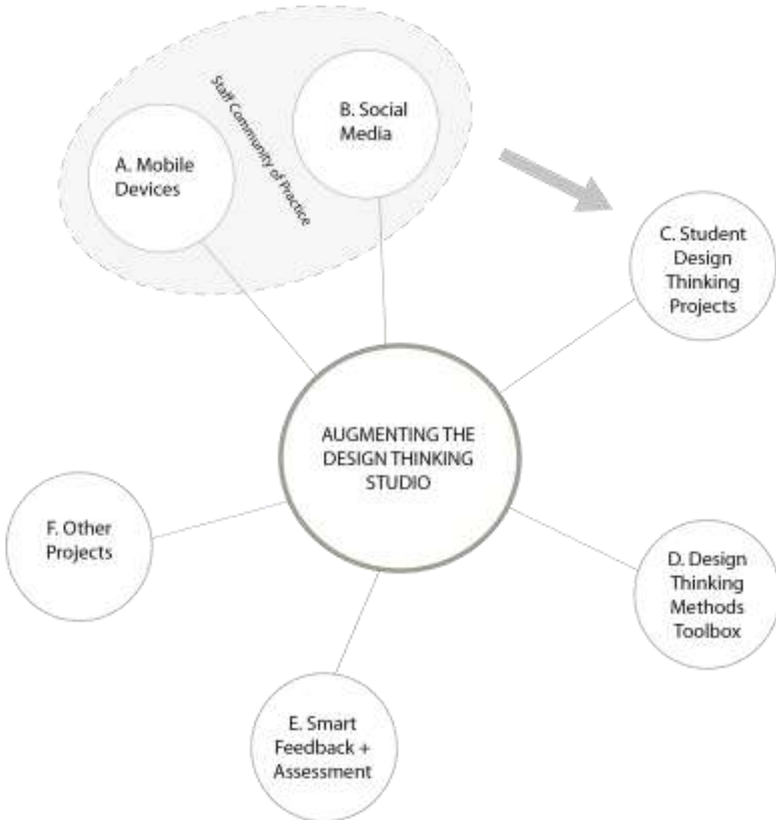

Figure 2: Key elements of the Augmented Design Thinking Studio project

Communities of Practice

To develop staff and student capability in the use of social media, a number of Communities of Practice (COP) were established within the programme. Communities of practice are based on a social learning theory (Lave & Wenger, 1991; Wenger, 1998). Wenger (2006) describes communities of practice as “people who engage in a process of collective learning in a shared domain of human endeavour" (p1). The learning communities for this project include:

- A formal lecturer community of practice;
- Each student year cohort; and
- Individual student project teams.

Lecturer COP

The establishment of the lecturer COP involved the brokering of the concept to key Product Design programme lecturers. This was approached in number ways. An interactive mind-map using http://www.mindmeister.com was created for the first lecturer COP meeting to outline and define the scope of the COP. Participating lecturers were then invited to collaborate on further development and construction of the mind-map using their mobile devices and the Mindmeister app, available for iPad, iPhone, and Android devices.

Table 1: Outline of the Product Design Lecturer COP

Steps/Topic	Pedagogical Implications
Establishing a COP	What is a COP? Expectations Ground Rules Informed by Action Research
Mobile Devices	Personal appropriation of iPhone 4S and iPad3
Creating an mPortfolio	Establishing reasons for the use of: Blogging, via Wordpress.com Twitter
Enhancing Productivity	Basic connectivity, collaboration and productivity tools: Email Google Docs Mobile Web Evernote
Managing Social Media	Establishing tools for filtering, collating, and curating mobile social media, and developing metcognitive skills as essential new digital literacies: RSS subscriptions via Google Reader Creating an interactive visual experience via Flipboard
Enhancing Pedagogy	Exploring the potential for mobile social media to enable student-generated content and student-generated contexts - designing collaborative learning experiences.
The scholarship of teaching and learning	Establishing a framework for practice-based research outputs based upon the design and implementation of mobile social media to augment the design studio experience.

Lecturer Feedback

Lecturers participating in the COP were asked to provide reflective feedback in their blog posts throughout the project. The following provide some indicative posts from Product Design staff over a number of weeks:

> Owning an iPad immediately changed a particular work habit I had: coming home and starting my laptop to work, do research, check e-mails, have Skype conversations etc. I do not feel the need of a computer anymore apart from when doing some stuff which require a bigger screen (e.g. photographic work) or using office programs… In this past month mainly passed by getting used to particular auxiliary technologies which can be used in conjunction with our mobile devices such as Apple TV, a Bluetooth speaker etc. This week happened the most exciting learning for me so far: Our technology steward introduced us to Flipboard. I have been following blogs, tweeting, reading news etc. using all separate applications. The capability of Flipboard to bring all these material together, present in an aesthetically pleasing way and enable sharing any of these collated material in any social media of my choice is fascinating. Currently I'm playing with Flipboard and trying to figure how to further refine the material delivered by it to my particular priorities. We'll see. I realise though, Flipboard (or any similar application) simplifies the hard task of keeping up with multiple streams of information flow. Discovering Flipboard has been a cornerstone for me; for the first time since the project started I

learned something new, experienced a new experience and maybe realised the scope of exciting learning's ahead. (Lecturer1 blog post, 2012)

May 17: I admit being a little sceptical of the benefits from engaging with an online community. Can't get a cup of sugar from down the road by tweeting. Unless they are tweeting back. They are not.
May 22: At today's session I made a giant step forward in grappling with managing these social platforms. Google reader is feeding flipboard. I can now cancel the herald subscription. It was full of trash anyway. Have been looking for an excuse to ditch it. Though it was Handy to light the fire.
May 30: A summary?
Dropbox. Has transformed the way I work. No files on a computer, and therefore accessible anywhere. Brilliant. Until an Internet connection is not available.
Twitter. Slowly getting to terms with the potential as a means to filter and broadcast information.
Qik. Got pretty excited about the possibility of live broadcasting a lecture across campus with the iphone. Thankfully prototyped it before the actual event - well and battery went flat. I see the potential for close up applications
Google reader. Paired with Flipboard it is opening up a vast amount of data previously not easy accessible
Flipboard. Lays it out beautifully
Pages. Great, but the keyboard is not user friendly. Needs arrow buttons to move cursor. I think.
Daily notes. A good way of recording meetings etc. I have now completely dropped visual diary. I do like a pen and paper, and can still use and photograph...
Viber. Ringtone needs some improvement. So many calls missed. iPhone 4. A ton better than the last.
iPad? Well I have to say it has been a pretty significant device. A few negatives around social interaction. In a physical sense.
Not so keen on blogging and public/private cross over. (Lecturer2 blog posts, 2012)

Analysis of the lecturer feedback indicated that the initial impact of the mlearning project was on personal productivity, but this was then followed by the experience of critical incidents where conceptual shifts in the pedagogical implications of mobile social media became apparent. The appropriation of customizable designer-friendly tools used by the lecturers in the establishment of the lecturer COP was a stark contrast to their previously limited appropriation of the institutions Learning Management System (LMS), Blackboard, that was used mainly for administrative and course information delivery duties.

Student Survey

A total of 24 Product Design students were surveyed at the beginning of the project to establish a case for the introduction of mobile social media into the programme, and to establish students' personal ownership of mobile devices, and their prior use of mobile social media. As Figure 3 shows, the majority of the students were consumers of social media rather than creators of social media content prior to the project. Additionally there was a surprisingly low level of smartphone ownership among these students, with the majority owning feature-phones with built-in cameras. Computer and Internet access were almost ubiquitous, as was the use of Facebook and YouTube viewing. There was therefore scope to expand students' prior mobile social media experience by the integration of mobile social media to augment the design studio experience.

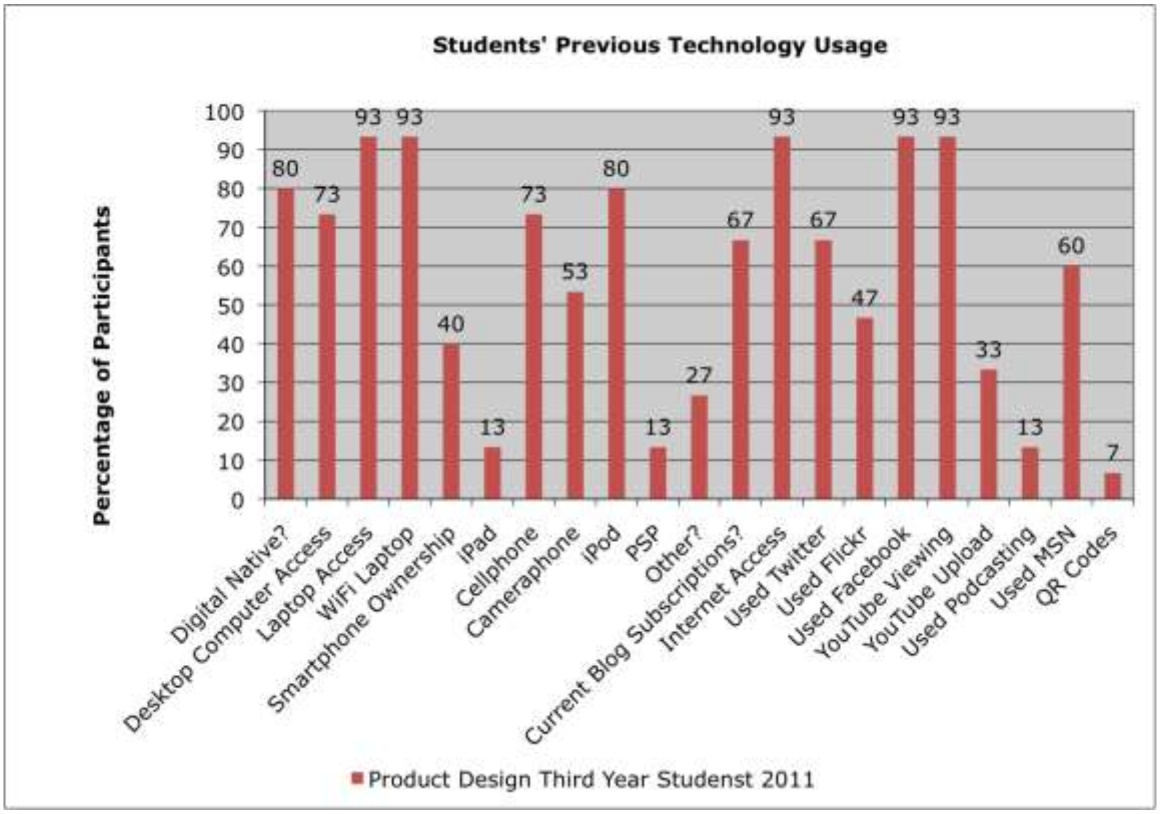

Figure 3: Product Design student previous technology experience

Students were also asked to identify the most useful functions of wireless mobile devices (WMDs). The results are shown in Figure 4.

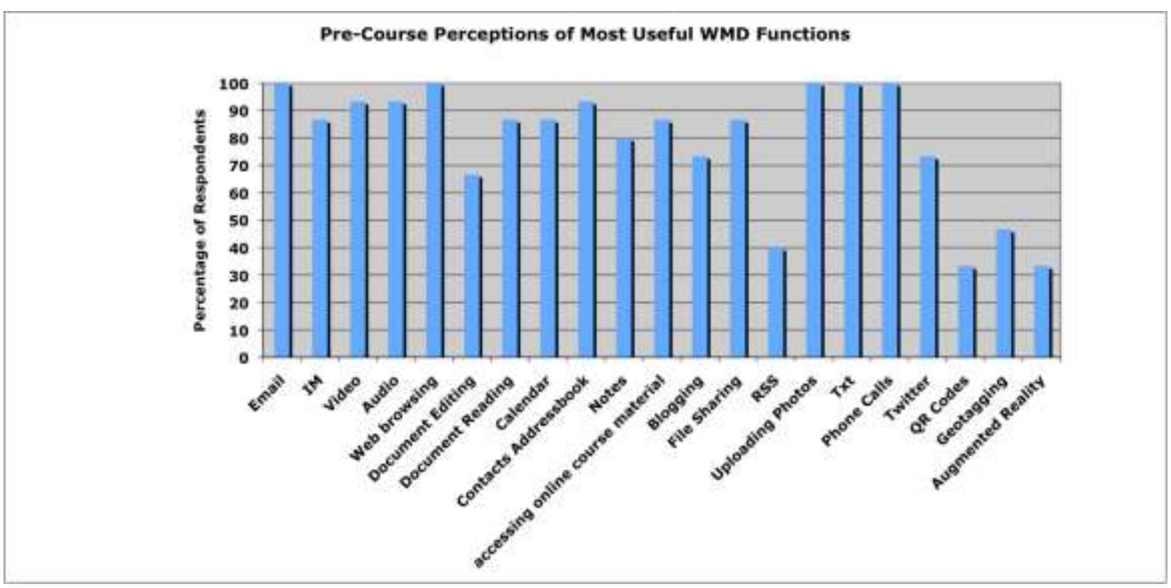

Figure 4: Product Design student perceptions of the most useful functions of WMDs.

The lowest rated functions represent the gaps in students' prior experience and use of smartphones, that is: the use of QR Codes, Geotagging (using the built-in GPS of smartphones), and augmented reality (using the built in GPS, compass, and accelerometers of smartphones). Additionally, as students social media usage was dominated by Facebook usage which does not make standard use of RSS for subscribing to social media, the students had little concept of what RSS was or its use in managing social media information. These then are the areas that can be explored for augmenting the design studio.

Previously the extent of course online activity had been the administrative use of the institutions Learning Management System (LMS) Blackboard, and an institutionally hosted installation of Mahara for student e-portfolios. In comparison to the level of student engagement and student empowerment evidenced by the previous student use of the LMS and Mahara, the level of student engagement and critical thinking as well as team work building evidenced via their use of mobile social media was revolutionary for the course and for the Product Design programme. This is evidenced by two initial, six-week student projects including a third-year Product Design studio project discussed below, and a first-year Product Design studio project introducing the Design Thinking process. Through the implementation of the project, a radical conceptual-shift in the understanding of the affordances of mobile social media to augment the traditional physical studio environment is occurring. In this case mobile social media is reassigned from the category of a purely social tool for informal use into a powerful tool for student-generated content and collaboration within student-generated learning contexts.

Pilot Student Project

The first ‘pilot’ mobile social media project undertaken with students was a third year Product Design studio project. The students, working in groups of three (reflecting small communities of practice), were asked to apply Design Thinking methodologies and processes to the in-depth research, analysis and the design of one or more 'product' interventions that clearly improve and enhance the experience of bus patrons (users) in Auckland. The project was undertaken in conjunction with Auckland Transport, a division of the Auckland Council. The Design Thinking process was underpinned by observation and role-playing research to identify poor experience ‘touch points’ in the Auckland bus journeys.

Key to the implementation of mobile social media in the project was the formation of a collaborative blogging platform using Posterous.com and the use of student-owned smartphones to augment the formal studio aspects of the Design Thinking process. Posterous was selected as a appropriate mobile blogging platform because of its clear and simple interface, ease of use, the ability to upload images and text from email, and because it had a good mobile app for smartphones and tablets. In addition to the use of blogs, students were also asked to undertake some of their research using social media platforms such as Facebook and Twitter surveys to enlist feedback on bus users experiences, and on the ideas and concepts that students generated through the Design Thinking process.

Given that this was the first implementation of mobile social media in a Design Thinking studio project, it provided a useful initial focus for engaging student feedback and for critical discussion by lecturers to identify issues and opportunities, and to help prepare for a more integrated approach in integrating mobile social media in the Product design programme. From the discussions a number of key issues emerged from the pilot. Some of these include:

- Generally many students enjoyed reflecting and writing more ‘freely’ about how they were going throughout the Design Thinking process. It is also good for students to be able to look back over the entire process at the end of the project;
- Lecturers felt that students were writing more than that had than in other projects;
- The blogs were very good for capturing and communicating the practical design work happening in the physical studio (see figure 5);
- The blogs worked better the early (research) phase of the project and blogging tapered off towards the end. Students did not do a good job of documenting the final design proposals;
- It was good for lecturers to see how the students were progressing at various points in the project, and this helped them prepare for when they met them in person (in studio) this discuss progress and ideas; and
- There was a little bit of confusion around the role of the blog in the assessment of the project.

Overall there appeared to be more cohesion in each the student groups than in previous projects, and it was good to see each group communicating, sharing and developing ideas outside of the formal studio situation. More importantly the use of social media in the project provided a platform that clearly extended the physical studio based learning environment, and demonstrated the potential of future development of the project with other student groups.

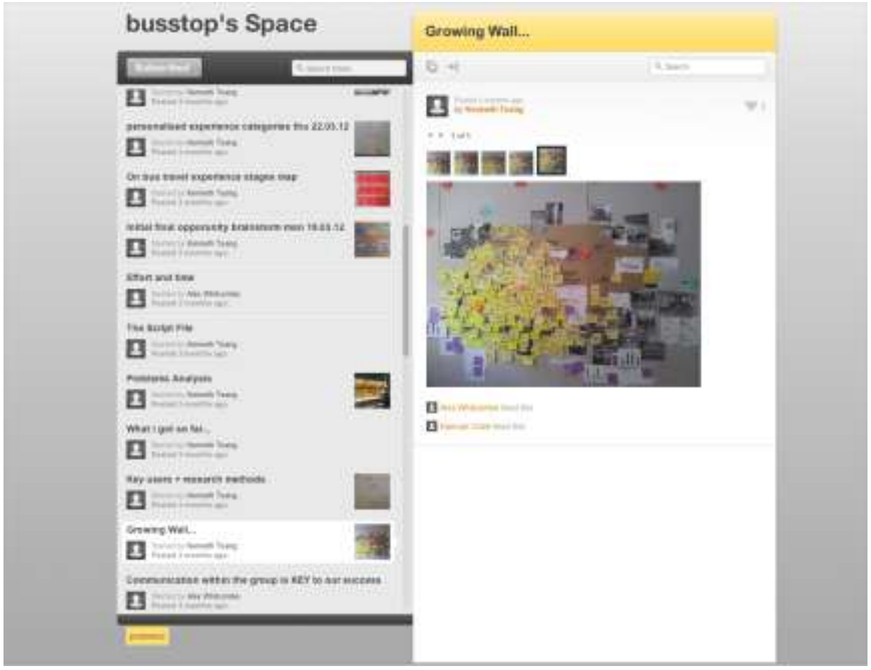

Figure 5: Example of one group's Posterous blog space capturing the work from physical studio

The results from the project were good, and feedback from the client was very positive.

> More importantly the substance, practicality and fresh thinking and concepts were outstanding. Please accept my congratulations to you and the faculty and also to the students themselves. Please encourage the students with the reassurance that their efforts will be incorporated into some of our new thinking.

Conclusions

This paper has described the ongoing implementation and impact of a mobile social media project to augment and enhance a Product Design programme underpinned by Design Thinking. A number of key themes have emerged from the research project to date:

Opportunity: Studios, while providing excellent environments for collaboration and creativity in the formal Design Thinking learning and teaching process, often insulate students from 'real-world' contexts required in Design Thinking methodologies;

Community of Practice: The establishment and nurturing of a lecturer community of practice investigating, experiencing and appropriating the use of mobile social media in the learning and teaching of Design Thinking has provided programme staff with a sound platform for engagement, discussion, and as a mechanism to develop capability and knowledge. This is the first step of what will be an ongoing process of ontological shift for the programme as the project develops;

Pilot Project: The first pilot project with students has provided both staff and students the opportunity to explore some of the key issues and opportunities for the implementation of mobile social media into the learning and teaching programme. Findings from the pilot project have indicated that mobile social media (tools and platforms) are beginning to, and have the potential to, further enhance the more formal aspects Design Thinking studio by providing opportunities for collaboration, creativity and reflection in 'real-world' contexts, and to positively impact the students learning experiences and Design Thinking expertise development; and

Pedagogical Change: Overall the exploration of the potential of mobile social media to augment a physical design studio paradigm has led to the first stages of an ontological shift in the understanding of both the lecturers and the students of not only how the physical learning space can be richly augmented, but also to enable student-generated content and student-generated learning contexts. This represents a move along the continuum from Andragogy towards Heutagogy.

The Augmenting the Design Thinking Studio project continues to evolve and develop and the findings of the first two student projects will be used to further develop future student projects.

‘Being in the kindergarten of blended learning’: Exploring teachers’ processes for sustainable blended learning practices

Yvonne Wood
AUT University

The potential of blended learning has yet to be reached and this paper presents an alternative lens for researching teachers who work with blended learning environments. The teachers’ role in creating blended learning environments is not yet well understood. This paper proposes the Social Construction of Technology (SCOT) as a model that may be used to explore the processes that teachers engage in when creating blended learning environments. Exploring the ways in which teachers are creators of blended learning environments provides a new lens for sustainable practice. This may signify a shift away from the focus of attempting to create a perfect product to an emphasis on sharing the process development. This paper first presents an overview of the SCOT model which is followed by examples of the ways in which the SCOT model was applied in a recent research project.

Keywords: Social Construction of Technology (SCOT), blended learning environment, blended teaching, sustainable process, teachers’ perspectives.

Introduction

Current research in the field of blended learning has focused on the use of technologies for learning activities and their inclusion in curriculum design. Motivation to use blended learning is evidenced in the literature in phrases that allude to “the best of both worlds” (Gruenewald, 2003; Nielsen, 2008; Ward, 2004) and the “hope for the 21st century” (Connolly, Jones, & Jones, 2007; Daniel, 1997). Daniel (1997) indicated that ideas for the potential of blended learning have been anticipated for some time, however much of this research has had a student focus and the area of teachers (as future makers), has remained under researched. There is a scarcity of literature that looks at exactly how blended learning environments are created by teachers from the teachers perspective. However, there is an abundance of literature about advice, design, and reports on what has happened (Bonk & Graham, 2006; Littlejohn & Pegler, 2007; Stacey & Gerbic, 2009). Accounts of the ways in which teachers are transitioning to blended learning are now appearing in the literature (Samarawickrema, 2009; Wiesenberg & Stacey, 2009; Wilson, 2011) however detailed accounts of the teachers perspectives are yet to be fully explored (Gerbic, 2011).

The SCOT model is put forward in this paper as a theoretical model that may be used as a lens to view the work in which teachers are engaged. Furthermore the model provides a way to investigate the iterative processes of creating blended learning environments, which may be used to focus on sustainable development. This paper theoretically locates the SCOT model, describes the four stage model followed by suggestions to mitigate the critiques of SCOT in the context of teachers’ practice in creating blended learning environments. The paper concludes with a brief overview of the SCOT model applied to a recent research project, highlighting aspects that may support a focus on teachers as future makers and their sustainable practices.

Concepts underpinning the SCOT model

SCOT provides a theoretical perspective for understanding technological development from within the constructivist paradigm. The basic premise of the SCOT concept is that there is no one correct way for technologies to be developed and that variation in development occurs as a direct result of the different people involved and their social connections (Pinch & Bijker, 1984). Prell (2009) expands the SCOT definition stating that: “Technologies emerge from social interactions among social groups... SCOT sees no 'right' or 'wrong' technologies, as all technologies have the potential to be shaped differently” (p. 2).

Foundational to the SCOT model is that there are various ways in which technology could be developed. Oliver (2011) contends that SCOT can be used as an alternative way to conceptualise the relationship between education and technology which has often been deterministic in nature. Pinch and Bijker’s (1986) concept counters technological determinism that allows for only one right way in which technology can develop.

Therefore it is a good fit to apply the SCOT model to viewing the multifaceted field of blended learning. One of the challenges in the field of blended learning is that there is great variation between how this concept is understood and applied. Sharpe, Benfield, Roberts and Francis (2006) specifically stated that “the term blended learning is difficult to define” (p. 24). Pinch and Bijker state that there are many ways in which artefacts could be developed (‘artefact’ is the terminology used in SCOT to describe technological developments), as a result of the different people involved (which in SCOT terminology are referred to as the relevant social groups [RSG]) and the choices they make in the construction of their technology use.

The SCOT model

Pinch and Bijker (1984) developed a model comprised of four interrelated stages which are RSGs, interpretive flexibility, closure and stabilisation (Pinch & Bijker, 1986; Prell, 2009). Table 1 is an adaptation of Prell’s (2009) presentation of the model with a brief description and key concept displayed beside each of the four stages.

Table 1: SCOT four stage model adapted from Prell (2009)

Stages in the model	**Key concepts**
1. Relevant Social Groups (RSG)	May or may not be members of the same institute RSG has a shared interpretation of the artefact
2. Interpretive flexibility	Numerous interpretations of the artefact exist Each RSG has their own interpretation
3. Closure	Multiple interpretations cease to exist Interpretive flexibility diminishes and an approach is chosen
4. Stabilisation	The development of the artefact within the RSG This happens in degrees

The SCOT assumption that technologies are socially constructed and shaped by the people active in the development process is the starting point for the SCOT model. RSG is the term used to describe those involved in the process. Once the RSG is identified, the focus then moves to “interpretive flexibility” which is the beginning of the development phase where numerous possibilities and variations are explored. When the development phase becomes concentrated on one particular idea, the artefact is said to have reached “closure” where the RSG reaches agreement to develop aspects of the artefact (for example the Learning Management System [LMS]) and “stabilisation” when the actual artefact is developed. The stages of the SCOT model are expanded upon next with the connection to social constructivism highlighted.

SCOT Stage 1: RSG

Defining the different people involved and categorising them into RSGs is the first stage of the SCOT model presented in Table 1. RSGs are defined as a group that shares a common purpose or understanding of the artefact (Prell, 2009). The primary reason for identifying a RSG is to provide a useful starting point for research, however it is also noted that some researchers may find this too simplistic (Pinch & Bijker, 1986). Humphreys (2005) recognises that “the choice of relevant social groups is highly subjective and dependent upon the researcher” (p. 234) and that this is a way in which to simplify the focus that may include biases. Pinch and Bijker (1986) assert that the RSG need only be sufficiently defined for the context at hand, and that exhaustive locating of social groups was not the goal since “all groups and structures are themselves embedded within an endless web of other groups and structures” (p. 353). This approach is well aligned with social constructivism.

The term RSG indicates that there can be more than one group, and research can focus on a particular group or several RSGs, which may or may not be from the same institution. The RSG may be a group that has existing connections, or the connection may be constructed entirely for the purpose of the research where people with similar views of the technology are considered as a RSG (who may never have met or have little connection in real life).

SCOT Stage 2: Interpretive flexibility

Creating multiple interpretations for the artefact is the definition of the interpretive flexibility second stage of the SCOT model (Pinch & Bijker, 1984). This is an explorative phase during which different ways of designing and working with the artefact are explored. The theoretical position of SCOT is that all technologies could be different and the final design is dependent on the RSG (Pinch & Bijker, 1984). The malleable nature of technology is inherent in this stage of the SCOT model; it is the different interpretations of the artefact by the RSG that is explored. This is supported by Meyer and Avery (2010) who noted "studies that unearth the developmental stages of a technology and follow it through its implementation phase show that users are not passive [and] they are capable of interacting with technologies in ways the designers may not have predicted" (2010, p. 158). Humphreys (2005) contends that there can also be flexibility of structure concerning how the artefact is understood. Pinch and Bijker (1984) clarified that interpretative flexibility applied to both the way in which people thought about the artefacts and the variety of ways in which the artefact could be designed and used.

The way in which the artefact is interpreted is therefore flexible and socially constructed by the RSG. Interpretive flexibility is the stage where variations are explored by the RSG. The socially constructed ideas may be developed within and between RSGs (Pinch & Bijker, 1984) and also potentially within sub-groupings of RSGs (Humphreys, 2005). The first two stages of the SCOT model are closely connected and demonstrate the connection between social constructivism and the SCOT model.

SCOT Stage 3: Closure

Closure occurs when the RSG develops a tighter definition for the artefact and defines how the technology has become an accepted part of their practice (Pinch & Bijker, 1984). Prell (2009) describes closure as a diminishing of interpretations, and Bruun and Hukkinen (2003) identify closure as the streamlining of interpretations. To clarify the shift from interpretive flexibility to closure, the RSG moves from multiple interpretations in interpretive flexibility to a shared definition of the artefact in closure. There are several ways in which closure is reached ranging from a redefinition of the problem, rhetorical closure, or consensus of a definition by the RSG (Humphreys, 2005; Pinch & Bijker, 1984). Bruun and Hukkinen (2003) state that closure is never truly reached and that technology continues to develop. However, this is not necessarily seen as a problem because technologies are constantly evolving, which becomes part of the development cycle (Pinch & Bijker, 1986) and process of technology development (Bijker, 2010). The approach by the RSG viewing technology as a development process is the point at which SCOT may be used to explore continued and therefore sustainable practice adopted by the RSG.

SCOT Stage 4: Stabilisation

Stabilisation, the final stage in the SCOT model, occurs when the actual artefact is developed and used (Pinch & Bijker, 1984; Prell, 2009). Stabilisation may happen in degrees (Pinch & Bijker, 1984) or as a fluid process (Prell, 2009), where the refined definitions attached to the artefact are developed over time both within one RSG or across different RSGs. To expand this point further, the development of ideas across the RSG must allow time for the social interactions (social constructivisim) to take place, and the clarifying of definitions may take several such interactions. Rosen (1993) clarifies stabilisation in that "the characteristics of this artefact then come to be 'taken for granted' as the essential 'ingredients' of the technology" (p. 483). Stabilisation can therefore be described as both a social and a slow process. Humphreys (2005) identifies the major critique of stabilisation, in that Pinch and Bijker (1984; 1986) do not state what happens if stabilisation is not reached (they only go so far as to say that it happens in stages). Humphreys (2005) raises concern that this process of stabilisation happening in degrees is insufficient and suggests a more flexible approach, by focusing on the way in which the artefact is spoken about, used, and structured.

Closure and stabilisation are described as "two sides of the same coin" (Bijker, 1997, p. 85). Humphreys (2005) further characterises the distinction by stating, "the most pertinent difference between stabilisation and closure is that closure is about relevant social groups while stabilisation is about the artefact" (p. 243). These explanations provide a simple way to distinguish between the last two stages of the model.

Critiques of SCOT concept and model

There are a number of critiques of the SCOT concept, focused primarily on the RSGs and the overemphasis of their function (Jasanoff, 2004; Russell, 1986; Winner, 1993). Initially SCOT critics argued that SCOT was a form of social determinism (Hughes, 1994; Lipartito, 2003; Russell, 1986) in that although SCOT views the many possibilities for development of the artefact, the choice of and focus on RSGs that shape this development is linear and determined by the researcher who might only focus on the groups that had successful impact on the development, as opposed to groups that did not influence the development, thereby being deterministic in approach. Winner (1993) continues this line of argument by stating that SCOT research is superficially focused on the chosen RSG and does not allow for other groups to be considered.

In the context of applying SCOT as a lens to view teachers practice in blended learning, I contend that multiple RSGs can be used to focus on the different aspects of blended learning usage. Multiple views of different RSGs can be clearly explored using the SCOT model.

The next critique takes this point further by stating that SCOT excludes the RSGs who do not influence the development of the artefact (Wajcman, 1995, 2010). The idea that is of note within this critique, is that issues of social power and political standing are not addressed by SCOT (Winner, 1993). The social groups whose ideas are not considered are ignored, and even more concerning is that those without a voice are ignored completely, thus allowing for a selective view of technological development (Winner, 1993). This critique generated a subfield within SCOT research led by one of the seminal authors concentrated on ways in which users (and non users) of technology have important consequences for research (Oudshoorn & Pinch, 2003).

Variations of the SCOT model have been developed that extend the model beyond the first four stages. Most notably Bijker (1994) extended the model with a further four stages to enable research to include a focus on the issue of power relationships (which is also the model that Prell [2009] extends). Bruun and Hukkinen (2003) propose the combination of models: evolutionary economics (EE), SCOT and Actor Network Theory (ANT). Alternatively, Dayton (2006) explores the full cycle of development within a workgroup "as they collectively learn, analyse, adopt, and redefine a new information technology (IT) tool or system" (p. 355). In order to see these developments fully, Dayton combines SCOT with the adoption and diffusion theory (ADT, first put forward in 1962 by Rogers [2003]) and cultural–historical activity theory (CHAT, developed and discussed in relation to social construction by Engestrom, [2000]). Other strategies to mitigate this critique would be to select multiple RSGs to represent the different roles (users, producers, bystanders and advocates) in technology development (Humphreys, 2005) or to potentially create a new model in the application of SCOT.

Utilising SCOT to focus on the application of software is supported by the research conducted by Jump (2011) and Prell (2009). More specifically, I contend that the SCOT model can be used to research the teachers' use of software in the creation of blended learning. Van Lieshout, Egyedi, and Bijker (2001) found in relation to teaching with technology that "it depends almost solely on the intrinsic motivation of individual teachers" (p. 14), which I contend is a valid point in relation to the current technologies and investigation into the teachers' processes. Literature concerned with the application of SCOT highlights the need for research studies that focus on the actual use of technology (Bissell, 2010; Edgerton, 2004; Winner, 1993). Specifically, in the area of ICT it has been noted, "the whole area of practical use of ICT-supported learning technologies appears to be under-researched" (Bissell, 2010, p. 539). Winner (1993) critiques SCOT for ignoring the consequences of technologies after they have been developed. Therefore, it may be important to plan for research projects that follow development beyond the development phase through to the practical application of ICT in blended learning environments.

SCOT applied to a specific research project

My research project focused on applying the SCOT model to provide visibility of the ways in which teachers create blended learning environments, a necessity argued by Cornford and Pollock (2002). Researchers in blended learning have found that the role of the teacher is changing significantly (Kaleta, Skibba, & Joosten, 2007). How teachers are actually changing their work, and the approach they use when creating a blended learning environment, is the gap on which my research project focused. The project I undertook was a masters thesis investigating "Teachers' creation of blended learning environments at a campus-based university" (Wood, 2011). The project was focused on the practices within a single university in a large New Zealand city. Purposeful sampling including snowballing was used to select the six teachers from different study areas across the university. The way in which the teachers who participated in the research study were identified as an RSG stemmed from their descriptions of their role that empowered them to make changes with the LMS (specifically Blackboard™ at the case study site). Their shared belief was that they could shape the LMS to suit their own teaching practice and that this was a choice they had made at differing stages of the LMS implementation. It is important to note that the teachers in this research study were not all early adopters of the LMS technology.

Interviews were selected as the main data gathering tool to support the investigation into discovering the new invisible work that the teachers had undertaken in relation to developing blended learning environments. Specifically a two-phase semi-structured interview was the main tool used to collect data, which was supported by a demographic detail form. The data gathered from the interviews was in the first instance analysed thematically with the use of mind mapping. When it became apparent that the rigor of the case study could be improved by the application of a theoretical model, the SCOT model was applied strengthening the connection to the social constructivist case study approach. To summarise, thematic coding was the first cycle of analysis which generated broad themes. The SCOT model was the second cycle of analysis applied to the themes generated in the first cycle. The next section of this paper highlights the way in which the SCOT model was applied in my research project.

SCOT Stage 1: RSG comprised of teachers using the LMS

Pinch and Bijker (1986) stated that it is useful for researchers to identify the RSG and their shared interpretation of the artefact as a starting point. The RSG in this research study was based on identifying the teacher participants as active users of the LMS. The participants' shared interpretation of the LMS was that they each recognised a potential to improve their teaching practice through incorporating the LMS. The choice to use the LMS was made of their own free will, and while it was strongly supported by the institution, it was not a requirement. This RSG of teachers shared interpretations were founded on their willing and autonomous shaping of the LMS to develop their own blended teaching practice. The research project revealed that the teachers self-directed choice to use the LMS, and the influences that supported them, were critical to their engagement in the blended learning design process. The use of institutional support was evident in the range of grants and individual work that the participants undertook utilising a range of training options. Therefore these supporting internal and external influences may be important considerations for teachers generally when engaging with the blended learning design process. Lindsay (2003) states that users actively co-construct their identity in relation to the technology they use, these identities could then be used to develop sub groupings for future research. Meyer and Avery (2010) heralded the need to specifically focus on teachers as users of technology. These distinctions could be used in future research projects as the foundation for additional sub groupings within the RSG focusing on teachers as users of technology and the ways in which they co-construct their identities.

SCOT Stage 2: Interpretive flexibility in the teachers' exploration of the LMS potential

Interpretive flexibility in my research project was characterised by the participants' experimentation with the LMS and the range of potential they described. The data show an exploratory phase in which the participants focused on using the new tools that the LMS afforded. Exploring the use of new tools led to many interpretations of the way in which the LMS could be used. Experimentation was a pivotal aspect of interpretive flexibility. The project illustrated that in essence the teachers chose the better of the two environments (online or face-to-face) for their learning content as a result of exploring the LMS options, and decided what to put back into the face-to-face classroom. Awareness of this possibility drove the participants to experiment with the ways in which the LMS allowed them to create the best blend of both environments. The participants focused on what the addition of the LMS allowed them to then do in their face-to-face classroom, rather than just focusing on the LMS technology and what they could do online, revealing a dynamic impact between the LMS and the face-to-face settings. Interpretive flexibility made the dynamic nature of the blended learning development process apparent. Power (2008) suggested the need for investigation into how teachers plan for online teaching. An interesting way to extend Power's suggestion would be to investigate how online teaching may impact on face-to-face teaching, thereby taking a holistic view of the impact of blended teaching.

SCOT Stage 3: Closure in the teachers' approach to continued use of the LMS

The final two stages of the SCOT model are closure which focused on the people and stabilisation which focused on the technology (Humphreys, 2005). Table 2 clarifies the nuanced distinction between these phases in relation to my research project.

Table 2. The distinction between closure and stablilisation

Closure	Stabilisation
Focus is on the RSG (humans – in this case teachers) and their approach to using the LMS	Focus is on the LMS (technology) and how the technology is put to use (developed)

SCOT closure is the stage where the teachers shifted from multiple interpretations about the LMS to a focus on their practice and how they would approach using the LMS. A key idea expressed by the participants was that they were at the beginning of developing their own blended learning practice, which one participant identified as being at the kindergarten stage of blended learning. The LMS had become an accepted aspect of the teachers' practice and they could no longer imagine teaching without the LMS. The participants described their plans for using the LMS, the associated procedures and administrative tasks as well as LMS uptake by their wider team. These factors provide evidence of the LMS becoming a fixed aspect of their individual teaching practice which included an acceptance of the continual development that was required to maintain the use of the LMS. Their approach demonstrated closure in the development of their preferred teaching environment and in the commitment to the long term development processes the LMS required. As a result the teachers developed a mature and sustained understanding of the purpose of the LMS and the impact it had on changing their approach to blended teaching with the LMS technology. These descriptions may go some way towards "[taking] stock of what it is that teachers now do" (Selwyn, 2010), and illustrate the broader range of planning and procedures that teachers now need in order to become proficient in managing their teaching context. These concepts illustrate how SCOT may be used to highlight areas to focus on in the development of a sustainable approach to blended teaching practice.

SCOT Stage 4: Stabilisation of the teachers' implementation of the LMS

Stabilisation is the stage where the LMS technology was physically developed through use of the LMS by the RSG. The technology in this research study was software, therefore it was the configuration (and implemented use) of the LMS software that constituted technological development. It is important to recognise the intangible nature of the LMS software. While the participants did reach stabilisation in their application of the LMS, Prell (2009) describes the development of software as a fluid process of stabilisation. The participants view that their course with the LMS could continue without them (in case of an emergency), signaled that development had taken place, indicating achievement of Pinch and Bijker's (1984) concept of stabilisation. However, ideally the participants wanted to perfect their LMS course prior to sharing the LMS aspect of their blended environment. The participants developed a clear way of working with the LMS through their application of the software, which illustrated Rosen's (1993) view that stabilisation may be observed when the technology is perceived as essential and "taken for granted" (p. 483), a sentiment that the participants clearly expressed. Teachers thought that it would be difficult for others to pick up their course, and this indicated that although the LMS had reached a certain level of stabilisation, that stabilisation, like closure, happens in stages (Pinch & Bijker, 1984). This research study identified that the participants were focused on passing on a finalised LMS artefact rather than a descriptive exemplar of the process in which they had engaged, in regard to their work with the LMS technology and in their incorporation of the LMS into their blended learning environment. Bijker's (2010) recent call for a focus on the process of technology development may now provide a focus for both interpreting the findings and signifying areas for further research. Describing the process of blending and documenting suggestions for improvements could be one way of working with teachers to identify sustainable practices for LMS development within their blended teaching practice.

SCOT insights regarding sustainability

This paper has shown that the Social Construction of Technology (SCOT) is a model that can be used as a lens to view the process of creating a blended learning environment. The SCOT model highlighted the contradiction the teachers experienced in the last two stages of the SCOT model: The sense of still being in the kindergarten of blended learning in the closure stage yet the desire to share the perfect course in the stabilisation stage. The SCOT model highlights the complexity of the continuous process in developing blended learning. The participants hoped that synergies could be gained from their work for future users of the LMS. In essence the teachers' hoped that their work was both transferable to other future makers and sustainable, they wanted to share their experiences across the university when their courses were perfected.

Laurillard (2008) cautions that education has been on the brink of transformation for some time, necessitating a focus on teachers' practices, supporting the use of the SCOT model to focus on the process of creating blended learning environments. Bijker (2010) emphasises the benefit of applying SCOT as a tool to investigate the process of technology development. Rather than waiting for the perfect blended course to be created, it is imperative to focus on the process of creating the blend, due to long development cycles in education and the fast changing nature of technology developments. Therefore the findings from the research study indicate that it may be appropriate to focus on creating exemplars that highlight the process of blended learning, and that also are developed during the development process rather than at the conclusion of the teachers perfected blended learning creation. This view is supported in the research by Hallas (2005) and Moron-Garcia (2006) who recommend the sharing of exemplars within the institution, providing insight into how the LMS is currently used and how it could be applied by future users. Bates and Sangra (2011) also suggest that effectiveness is increased when localised projects are connected to the wider context and strategy of the institution. Cornford and Pollock (2002) call for visibility into how teachers create the blended environment, to which providing such exemplars focused on the process could be one part of the solution. A focus on the process could entail the participants sharing of how they first learnt about and then explored the multiple possibilities of LMS, which they then refined through reaching closure and stabilisation (in essence each stage of the SCOT model).

Conclusion

This paper has outlined the SCOT model and a potential way in which this model may be applied to research to gain insights into opportunities for sustainable practice. One of the key findings highlighted by the application of the SCOT model to a small scale case study research project was that a contradiction was revealed between the teachers approach and development of blended learning environments. In their professional development the teachers expressed that they were at the beginning of learning about blended teaching which was likened to being in the 'kindergarten' of blended learning also suggesting long term and iterative development cycles. This contrasted with their desire to prepare for succession and develop the perfect course for dissemination. Perhaps the potential for blended learning has not been reached because the participants were not ready to let go of their creations; they wanted to perfect their work first before handing it on, which may be an unobtainable ideal. The foremost recommendation from the research study this paper was based on was "to focus on the way in which teachers navigate the process of shaping their blended practice" (Wood, 2011). Furthermore I contend that the focus on how teachers navigate the process of blending may lead to the development of sustainable models and capture the kindergarten like enthusiasm for the creation of blended learning during the early development stage.

Treading carefully in Stalk Space: Social Media and Risk

Carolyn Woodley
Sir Zelman Cowen Centre
Victoria University

Scott Beattie
Faculty of Law
Australia Catholic University

Universities are enthused by the capacity of social media to engage students, encourage creativity, support collaboration and connect students, teaching staff and industry globally. Without dismissing the very real capacity for social media to contribute to a connected, informed, critical digital citizenry, it is timely to consider some of the risks that social media in a university setting brings. It is a commonplace assumption that, not only are all students ‘on’ Facebook, but that universities must also engage with students there. This paper does not consider whether to use social media or not for teaching; rather, this paper introduces some legal and ethical themes about the use of external social media for the formal teaching of enrolled students.

Keywords: social media; university; risk.

Introduction

This paper draws on draft guidelines developed to provide general advice about legal risks and teaching with social media. While it was unclear how many staff in the Faculty of Business and Law at Victoria University (VU) use social media in formal teaching, it was clear that staff were devising their own rules: some think it is fine to be ‘friends’ on Facebook with current students, some think it is only alright to be ‘friends’ with Alumni. Some staff have Facebook sites to provide a social support space for students. Some staff do not use Facebook at all. Students also have diverse views about using Facebook for formal study: some students use Facebook for team work as well as extracurricular information; other students are frustrated by the fact that Facebook seems to be the only place where their questions are answered. A recent survey indicates that students are polarised about using Facebook for teaching with some describing it as ‘brilliant’ and others simply as ‘a bad idea’ (Woodley, Meredith and Murray, 2012). With mixed attitudes to social media from staff and students as well as eclectic teaching using social media, draft guidelines were developed to raise awareness about legal risks connected with social media.

Part of the ambiguity about using Facebook for teaching comes from a lack of clarity in the purpose of using social network technology in the educational context. In universities, social networks often take the place of previous media to send messages, distribute content, facilitate discussion or post calendar events, which are all features of online learning systems. Teaching staff need to consider the question: why use an external social media site if internal tools can achieve the same results? While some university-supported learning management systems (LMS) have social media capacity with wikis, blogs and networking functions, this paper concerns social media that is *not* supported by the university, does *not* require a university-issued password to access, which requires a student to register with an external company and which could be open to the public. LMS 'safe havens’ are not the focus.

Background

A range of VU university policies and state and federal legislation is examined in this social media discussion. In this discussion, we do not conflate the terms social media, Web 2.0 and user-generated content; rather, Web 2.0 is “the platform for the evolution of Social Media”; social media “is a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0”; social media allows for the creation and exchange of User Generated Content” (Kaplan & Haenlein, 2011: 61).

The need for existing policies and laws to be reasserted as a part of social media discussion is highlighted by eminent cases in mainstream media. Stalking and harassment laws have particular relevance online. More parochially, the popularity of a student-supported Facebook site called VU Stalk Space creates a cause for concern. While technology is ahead of the law in respect of social media, technological newness “does not compel new laws, but it does mean existing laws need to be applied” (Short, 2012).

While most Australian universities are associated with unofficial Facebook sites that follow the ‘Stalker Space’ model, the culture and tone of each site can be drastically different. 'Stalker Spaces' are student-run Facebook groups where students share unofficial information. The whole social gamut of student-to-student interactions is publicly visible: from swapping books through to harassment and bullying. Stalker Space sites are associated with official universities through the appropriation of the university logo or a parody thereof, references to university clubs, campus references and campus photos and student activities. The extent to which a university can control activity on a Stalk Space is interesting: too aggressive an attempt at control would create a social media back lash; whereas ignoring the space might amount to a dereliction of duty. Buchanan (2011) labelled Australian universities’ Stalker Space Facebook sites as sinister, citing the ANU site’s motto: "Stalk, prey, love"’ as evidence enough (Buchanan, 2011). It seems that universities have some duty of care to both its students and staff who could be described, named or threatened on these sites.

General participation on social media sites can expose staff, students and the university to a range of legal risks but using social media for teaching raises specific risks. In flagging risks, the benefits of using social media might be more apparent and the risks reduced. Teaching staff must be supported to better manage social media risks and to prepare students to be digital citizens. In developing students’ Web 2.0 literacies, teachers must also understand their own duty of care. Recent legal decisions have seen “that website owners can owe a duty of care to their users… profile pages of individuals can be used as evidence…and that …legal risk is growing just as fast as the ever emerging technology” (Dundas Lawyers, 2011). Users need some guidance to consider the risks of using social media.

Web 2.0 technologies

The appeal of social media to educators is obvious. Students Facebook through tutorials, Tweet through lectures or blog an assessment task. Student propensity for social media usage, however, does not of itself make a pedagogical case for using social media. Various research has demonstrated social media’s capacity for peer supported learning (Dabbagh & Reo, 2010), support for students in transition (Woodley & Meredith, 2012), enhanced internationalised curriculum and increased avenues for communication, connection and learning. The possibilities of social media and collaborative learning are considerable (Minocha et al, 2009). What is known about considered use of social media for teaching and learning is invariably encouraging. However, teaching staff also need to be aware of the legal context of their practice and that ill-considered social media usage could put themselves, their students and the university at risk.

Externally hosted social media networks

University-supported social media has several advantages over externally hosted sites both legally speaking and as far as support is concerned. Information Technologies Services (ITS) can assist with support issues, students can be enrolled and passwords issued from central student administration, the university can control the longevity of the site and, importantly as far as the *Privacy Act* is concerned, sites are password protected. Password-protected sites do not guarantee students’ privacy as that depends on what material other online participants make available. However, the password-protected status of university-supported sites should be emulated in using social media for teaching as public learning can be a daunting prospect.

It is the public – or potentially public – nature of social media that creates concern. Arguably, students should not have to participate, be assessed or be identified in any way on a publicly visible site in order to undertake a subject. Students might have the option of making their work public after the assessment is complete – but assessment or learning activities should not become public beyond the community of learners in the class. Before adopting a social media product for a particular teaching and learning approach, it is advisable to check whether the institutional Learning Management System or other supported platforms such as PebblePad can provide those Web 2.0 tools that meet particular teaching needs.

Social media encourages interactive communication, enables posting of messages through a simple interface and allows the sharing of messages across a broad network of contacts. Online messages can open up discussions with other contacts and other private networks. A piece of media can spread from private network to private network and take on a public character. This allows messages to be spread virally. The speed and ease at which content can be disseminated creates risk if user-generated comments are offensive, discriminatory, incorrect or violate Copyright, Privacy or Intellectual Property legislation. The ephemera of the class room discussion are replaced by texts with a different legal status and those texts can be easily distributed. This can be positive and negative but the negative possibilities create real and actual legal risk.

Public, Private and Confidential

If an institution expects enrolled students to register with Facebook or other products, then everyone involved must understand the Privacy implications of that product. This is an educative step that demands more of participants than a clicked agreement on a screen. While some platforms allow a degree of control over privacy settings, it is by no means assured that students know how to do this. Privacy settings must be explicitly worked through with students. Developing students' understanding of privacy will help to mitigate risk that can arise from the deceptively social nature of social media: social situations can be private but the media permits the accidental creation of a posting that can become a global publication.

The confidential qualities of class discussion can also become public posts that are easily distributed to an online global audience. The private student can find themselves under very public scrutiny. Confidentiality and a sense of privacy are crucial for some learners. While teaching has public aspects and sometimes requires public learning activities, the relationship between teacher and student is a private one based on confidentiality and trust. Learning might have public aspects but assessment of learning and feedback on learning are essentially private undertakings. The privacy inherent in feedback on learning is supported by VU's Student Assessment and Progress Policy and by the *Privacy Act* which regulates the way in which organisations (such as a university) can use private information of individuals, here meaning students and staff and others who might be involved in university activities.

As well as university-supported sites, students may have multiple sites of social media engagement. This raises the issue of security. If students must register with an external social media platform, teaching staff need to consider not only how many passwords students might have in the course of their study but also the fact that students will often use the same password across platforms. This can create a potential security hazard as if one platform is breached, they could all be breached. A whole-of-course approach to social media usage might limit on the number of passwords a student should have and students should be encouraged to have different passwords for different platforms.

It is important to distinguish between open and closed networks. Open networks like Facebook have a mass audience and anyone can join. There are also closed networks which are limited to members chosen by an administrator. Closed networks help maintain the confidential learner/teacher environment, open networks allow more interaction with the outside world and allow networks to be persistent over time and to extend beyond the life of a class. Closed networks typically depend on a single group of students during a certain semester and have a limited life. For this reason, some educators prefer a platform that allows a whole-of-course approach to learning activities, communication and presentation such as PebblePad. Armatas et al (2012) highlight that PebblePad provides students with a flexible, safe system to upload their own content and provides them with a means of interacting safely with industry experts.

Other Relevant Policies

Whatever the teaching mode, teaching in Australian universities operates in a highly regulated legal and policy context. Workplaces provide complex legal contexts and social media is a somewhat uncharted workplace territory. Social media postings could lead to cases of wrongful dismissal, the exposure of confidential information or reputational risk. Legal risks include legislation and common law concerns such as trade mark infringement, defamation or negligent misstatements (Dundas Lawyers, 2012). Social media sites are regulated by anti-discrimination laws, the *Privacy Act 1988* and the *Copyright Act 1968* (Cth). Duty of care, negligence and the *Occupational Health and Safety Act 2004* are all relevant to staff and student behaviour on social media sites: from students taking photographs of themselves 'planking' on campus to students unwittingly letting predators know that they are alone in the university library at night.

Current VU policies need to be applied to a social media context. The Privacy Policy already makes it clear that student information needs to be kept private. The Academic Honesty and Preventing Plagiarism Policy applies equally to an online medium. The Equity and Diversity Policy for Staff might become relevant if staff were friends only with some students online. Similarly, the Discrimination, Harassment and Bullying Policies and State and Commonwealth Anti-Discrimination Legislation apply to online activity. The recent amendment to the *Victoria Crimes Act 1958*, with the introduction of the Crimes Amendment (Bullying) Bill 2011, extends the existing offence of stalking to cover '*serious bullying*', including online bullying. VU's Staff Code of Conduct applies to the online behaviour of staff just as VU's Student Charter applies to students' behaviour online. It is really a matter of staff understanding the social media context, the university taking responsibility for not only what students do on VU-controlled social media sites but sites associated with the university. Universities must educate students about responsible use of social media.

Conclusion

Social media highlights the need for a different set of knowledge and skills in the employability debate. Students need both legal literacy and media literacy. They need an awareness of the legal obligations, rights, systems and the legal discourse inherent in everyday contexts in online environments. These literacy skills are important in terms of employability, citizenship and being online. Some universities embed Web 2.0 media literacy skills in subjects or resources on line. Put simply, "University courses need to take more responsibility in facilitating citizen 2.0 competencies" (Alam & McLoughlin, 2010).

Continuance theory and teacher education

Noeline Wright
The University of Waikato

Continuance theory is usually related to the regular use of technology in the business/industry area. It attempts to explain why people either continue to use specific technologies in their work, or not. Essentially, it links to the perceived value to individuals' ability to work effectively, however that is understood in their workplace. In the profession of education, particularly schools and teacher education, the perceived value of continued use is not about individuals and their work, but about individuals' work with groups of students and what happens to learning when these digital technologies are used. Continued use is contingent on their students' positive responses to these technologies supporting learning. I examine, in the light of continuance theory, what happens when student teachers in an initial secondary teacher education programme report on including digital technologies on practicum. This includes reporting on the effect students' responses have on their subsequent attitudes and practices regarding digital technologies in learning contexts.

Keywords: continuance theory, digital technologies, initial teacher education, learning

Introduction

Continuance theory is usually related to the regular use of technology in the business/industry area. It attempts to explain why people either continue to use specific technologies in their work, or not. The technology acceptance model/continuance theory that Bhattacherjee (2001) reported on, for example, centred on business customers of a bank's online banking system. The bank designed an online banking system that customers used remotely. The bank then wanted to know how likely it was that these customers would continue using it. Was the tool easy to use, and did it support positive bank/customer relations? Continuance theory was used to describe the phenomenon of why the banks customers continued to use the technological solution.

In educational contexts, there is a growing awareness that 'customers' of the educational business – students – are quite ready and able to use systems and technologies and/or affordances as tools in their learning. Teachers can also be considered as 'customers' of the educational complex, but their use – and continued use - of technological tools in classrooms contexts is not clear-cut. Their behaviours, attitudes and perceptions range from enthusiasm to resistance, self-efficacy to aversion. These behaviours and attitudes persist even in the face of a plethora of technologies or affordances available, according to elements such as context, topic, concept, student group, level and access. With the advent of ultrafast broadband being rolled out to schools, this availability is growing, as is the expectation of use as part of learning. While this variety of provision and greater potential openness differs from the singular approach or system a bank is most likely to create for customers, it can exacerbate teachers' approaches to using digital technologies because of the potential for failure - of the technology itself, of the school's ability to supply appropriate infrastructure (robust broadband/wifi, technical support), and of the perceived threats to their preferred pedagogical approaches (Wright, 2010a, 2010b).

The variety and openness of the affordances and potential of digital tools for learning purposes, links to Pachler et al's (2010) socio- cultural analysis vis a vis young people's continued, and sometimes continuous, use of digital technologies. These researchers suggested that young people appropriate the tools for their own cultural, identity and meaning-making practices in daily life and treat them as normal accessories for living. This is not necessarily true for many teachers, whose own backgrounds may not have included similar technological tools, given the average age of about 44, of the teaching population in New Zealand (Engler, 2008). While students entering schools (whether primary or secondary) have mostly grown up in a world infused with digital and mobile technologies, teachers have not, and so are often learning from scratch what the potential is for these devices and affordances. Continuing to use tools that have not formed a natural part of one's pedagogical toolbox is therefore, for many teachers, a challenge. However, given that teachers will often experiment with how they provide learning, it is likely that they will develop regular digital technology use in classrooms if students' learning responses are positive. When teachers see their students concentrating on and completing tasks to a higher level than they might otherwise, they are likely to repeat using such approaches, resources, tools, even when they may be fully aware that trying out new things may be risky (Wright, 2010b). This paper identifies some emerging ideas about these points that may support teachers to develop their experimentation with, and continued use of, technological tools in classrooms.

Context and study design

The data generated from which the emerging findings arise, consist of initial teacher education (ITE) students' Moodle postings about their secondary school practicum experiences in which they used some kind of ICT (information communication technology) tool as part of a lesson. This lesson required students to plan a teaching as inquiry question to link to this ICT use, incorporating some means by which they gauged students' responses to this intervention, and sought to find out how well students retained learning from that lesson in subsequent ones. Because the past some ITE students were reticent about asking students for their feedback, some examples of how this gathering of feedback could take place were provided. These examples ranged from suggesting giving students Post-It notes to write response on (then attach to a large sheet of paper with the relevant question at the top as they left the room), to students working in small groups to make feedback notes, to individual questionnaires, or posting blog/discussion thread notes as appropriate. Some methods were thus more formal than others. All meant that the ITE student was in a position to gather in and review the responses and draw some conclusions from. They were also expected to note their associate teacher's response to this lesson.

Preceding this practicum task, students participated in three four-hour workshops in which the teaching as inquiry as a process was outlined. Other topics in the workshops included a focus on critical thinking and the web, ways of helping students to express divergent and opposing points of view through technological tools, Twitter as feedback tool, and how GoogleDocs can be used for collaborative purposes. These workshop experiences were designed to demonstrate possibilities for students to adapt for their own pedagogical purposes while on practicum, linking directly to their assessment task.

Ethical clearance was gained via the formal faculty committee process, and all students indicated either their agreement or refusal for me to use their practicum posts as research data. It was made clear that this data would not be used before their work had been assessed. Even though one of the 80 students refused granting permission, the participant cohort is large enough to draw themes from. Thematic analysis of the data continues, whereby I note repeated occurrences, particularly about ITE students' own responses regarding their level of confidence in using technological tools for learning. What they say about their own knowledge and experience while using these tools, and what they say about repeating or developing such uses, is also of interest.

What follows is a snapshot of emerging findings, focusing on four areas of interest: ICT tools (also described as digital tools or digital technologies), pedagogy, ITE student teachers' self-evaluations, and issues of continuance.

Emerging findings

ICT tools

Schools are not equal in their provision, thinking, dispositions towards, and access to, digital tools and devices. Some schools for instance, do not yet provide wireless access for either staff or students. Some also house desktop computers in dedicated rooms, accessed via booking systems. Other schools have COWs (computers on wheels) to avoid classes having to change rooms. This also makes access more nimble, although booking procedures also exist. Some departments within schools have access to different tools. For example, some departments might use digital cameras and may desktop computers in their classrooms or close by. Others might have access to mobile tools, or expect students to bring their own devices (BYOD). Some classrooms include television screens and/or data projector facilities and are wifi-enabled.

Some schools engage in the laptops for teachers scheme (Cowie et al., 2008) and provide an adequate technological and organisational infrastructure. However, even in schools where technological provisions are up to date, it was not unusual for the ITE students to report that the most common use of laptops and data projection facilities was the repeated use of presentation software – mainly by teachers.

They also reported on the obstructions to using technological tools. For example, student feedback often complained of slow internet speeds, or broken equipment, or unreliable wifi, or issues with logging on to computers. These are likely to affect teachers' willingness to continue using digital technologies as a part of learning. They dislike wasting learning time fiddling with equipment to get it to work.

Pedagogy

Essentially, when teachers used presentation tools on a daily basis, they have not changed the learning dynamics – the teacher is still up the front, and communication is principally channelled through the teacher. Students are powered down (Gee, 2003) and possibly turned off. The ITE students noticed that they often replicated their associate teacher's technologies and pedagogical practices, partly because it felt safe and located control and management with them. On the other hand, when ITE students introduced something else (such as inviting students to use their own devices, or using moving image tools like YouTube or Xtranormal), the learning environment took on a whole new flavour, with students responding differently.

Perhaps the different responses reflected the novelty factor. Students, the ITE students reported, were often excited by the activity/tools being something else. What we cannot gauge is the extent to which the Hawthorne Effect was operating. Mitchell, Bailey and Monroe (2007) for example, note that, "Initial student excitement, if any, at an innovative technological approach may quickly fade when technology is the expected "normal use" from their [the students'] perspective" (p. 78). In other words, was the heightened student interest and focus because it was something different, rather than their learning being enhanced? Was the newness and novelty why students engaged more deeply or readily, or was it because they had a greater part to play in the learning complex? Without the ability to test this over time, we cannot answer that. However, it is worth noting Wright's (2010) point when she says "if the new tools simply replace an old one (such as presentation software instead of overhead transparencies) with little else changing, then student engagement and interest will quickly revert to previous levels because nothing has essentially changed *for the learners*" (p. 11). In such cases, if student interest and engagement wanes and they become restless, then teachers may get disheartened and attribute this to the technology, rather than the sameness and predictability of the learning process. The more passive students are in a classroom, the more disengagement is likely to increase, and the more teachers may revert to known and safe practices and resources.

ITE student teachers' self-evaluations

A key requirement of the students' postings was having to evaluate their students' feedback against their own experience of the lesson and the technology. Many commented on their apprehension about seeking student feedback on the lesson, but were affirmed by many students' positive responses to their questions. A key component of this was not only how they asked for feedback, but also what their questions were like. Some ITE students asked for feedback on levels of enjoyment (even though this was warned against) and therefore gained little of use that could help them rethink the lesson. Those who asked targeted questions about some aspect of learning, had a lot more to reflect on and analyse. As a consequence, those students learned more from the feedback experience.

One student for example, used an online concept map tool for her students to learn about the links between photosynthesis and cellular respiration. She then asked them the question "Are concept maps useful for your learning?" On response showed a good understanding of the students' own ways of learning by saying "Yes, they helped me get a better understanding. It is easier because I am a visual learner". Another said they were a "good way to remember what you have learned without looking at notes". The ITE student was then able to decide on the value of such a task, and also learned how to improve for subsequent classes. This sort of feedback, where students had specific and useful comments to make, assisted the ITE students to be prepared to use such tools/affordances again on other occasions. This process of gaining student feedback may assist teachers in developing a continuance habit.

Issues of continuance

For teachers to continue to use technological tools as integral components of teaching and learning, reliable tools are key. ITE student teachers reported feedback similar to: "better computers/internet", "have the Internet actually work", or 'the laptops not always cooperating". Student teacher and school student frustration was noticeable across a broad range of contexts and lessons. Schools' firewalls that blocked access to sites such as YouTube also frustrated the student teachers. It was not uncommon for them to report that lessons planned around YouTube clips had to be abandoned because they hadn't known that the site was blocked, and they didn't have the forethought to use a clip downloader in advance. Alternatively, the Internet speed was slow, affecting lesson timing and the ability to show the clip.

If teachers have to continually second-guess how to access sites, or cannot rely on Internet speeds, they are less likely to continue planning Internet-based lessons or using other digital tools. Other organisational factors can interfere with teachers' desire to use these tools and affordances. For example, many schools ban mobile devices on campus. This precludes students using tools they already have and are used to using. This ban also means that it is difficult for student teachers to try out using mobile devices as learning tools without contravening school policies, and difficult for teachers in these schools to individually try out the potential of these devices.

Conclusion

As alluded to above, some tentative patterns are emerging about what continuance might look like in a school. Key factors affecting teachers' use of technological tools as integral to learning include: unreliable Internet provision, outdated hardware, access to tools (for example, having to book dedicated rooms with fixed equipment), firewalls, overlaying digital tool use over unchanged pedagogy. Bhattacherjee (2001) attempted to explain links between expectation and confirmation in continued use behaviours in bank customers. Teachers are entitled to expect that tools and resources will work as they are supposed to. When positive student learning confirms this, they are more likely to repeat and refine further use.

So, if it is possible to extrapolate from student teachers' experiences of using technological tools while on practicum to teachers' technologically enabled or disabled school environments, then some considerations linking to supporting teachers to develop habits of continuance with digital tools for learning purposes are pertinent. These might include thinking about the critical provision of robust and powerful broadband/wifi, allowing BYOD, and in-class access to the Internet and digital tools for everyone. If the infrastructure in a school is enabling, then it is probable that teachers are more likely to trust it.

Another critical layer is an extensive review of pedagogical practices that complement *students*' use of the tools, rather than being vested only in the teacher. The recognition that pedagogies which allow students to collaborate, meaning-make, concentrate on tasks and risk-take when learning with digital tools is important to address for teachers. Not knowing beforehand that the dynamics of classrooms may change can adversely affect teachers' sense of control and authority, possibly leading to an aversion to risk-taking and trials with unfamiliar tools, resources and practices. If teachers fully understand those factors, we may be in a position to predict that they will continue to use and integrate digital technologies as part of learning, particularly if they can expect that the tools are reliable, and that students' learning would be enhanced as a result.

Chapter 4 – Open, social and participatory media

Introduction

The emergence of open, social and participatory media in recent years is changing the landscape of technology practices. They are changing the ways in which users interact, communicate and participate with technologies. These technologies include social networking sites such as Facebook,[1] LinkedIn,[2] and Myspace,[3] blogs and wikis and microblogging sites such as Twitter.[4] They are being used for a mixture of social and professional activities. This chapter considers the impact of such Web 2.0 technologies on education and in particular how these new technologies are changing learning and teaching practices. It will consider their fundamental characteristics and look at the implications for learners, teachers and institutions. It argues that the impact on practice can be both positive and negative and that as a consequence educational institutions need to develop new policies and strategies to take account of these.

This chapter will consider the new forms of user behaviour that are resulting and provide examples of ways in which they are being used to support learning and teaching. The central focus is a critique of the impact of new technologies on education, which raises a number of key questions. What new digital literacy skills are needed? What does it mean to be a learner or teacher in this new environment? What are the implications for organisational structures and processes? What new learning spaces need to be developed to harness the potential of new technologies? Building on this chapter, Chapter 14 considers the new forms of online communities and interactions that are emerging in these online spaces. Chapter 15 looks at a social networking site, Cloudworks,[5] which has been developed to support the discussion and sharing of learning and teaching ideas.

[3] http://www.myspace.com/
[4] http://twitter.com
[5] http://cloudworks.ac.uk

The changing digital landscape of education

There can be little doubt that digital technologies now infiltrate all aspects of our lives; electronic plane tickets, ubiquitous wifi, mobile technologies and technologies such as smart phones and tablets are becoming necessities rather than luxuries for many. Certainly, within the developed world, most of us have an expectation of a certain level of digital connectivity; and indeed rely on it, feeling cheated or that we are working below par without it. The pace of change is unlikely to slow down, and arguably there are more fundamental changes coming as the true impact of embracing cloud computing in education becomes evident (Dong et al., 2009; Katz, 2008).

New technologies provide a plethora of routes for finding and using information and for communication and collaboration. Alongside the established communication channels of the telephone, email, forums and texting, the emergence of Web 2.0 technologies in recent years has added blogging (and microblogging), wikis, social networking sites, virtual worlds and Internet-based Voice Over Internet Protocol (VOIP) and in particular popular tools such as Skype which enable virtually free, Internet-based communication. Similarly information can now be distributed in multiple locations, and packaged and presented using a range of different multimedia and visual representations. Sophisticated repositories now exist for everything from shopping online to repositories of good practice and free resources. RSS feeds and email alerts enable users to filter and personalise the information they receive. Social bookmarking and tagging means that collective value can be added to digital objects; concept and mind mapping, tag clouds and data-derived maps are only some of the ways in which information can be presented in rich and multifaceted ways. Within this context we are seeing a number of trends:

- A shift from the Web as a content repository and information mechanism to a Web that enables more social mediation and user generation of content.
- New practices of sharing (such as the use of Flickr for images,[6] YouTube for videos,[7] and SlideShare for presentations)[8] and mechanisms for content production, communication and collaboration (through blogs, wikis and micro-blogging services such as Twitter). Social networking sites provide a mechanism for connecting people and supporting different communities of practice (such as Facebook, Elgg[9] and Ning).[10]
- A scale or ‘network effect’ is emerging as a result of the quantity of information available on the Web; he multiplicity of connectivity and the scale of user participation, and as a result new possibilities for sharing and harnessing these 'network effects' is occurring.

These trends point to new ways in which users are behaving in online spaces. They provide a range of opportunities for supporting learning and teaching practices. The Web

---

[6] http://flickr.com
[7] http://youtube.com
[8] http://slideshare.com
[9] http://elgg.org
[10] http://www.ning.com

is now more participatory, supporting more open practices. The nature of openness is discussed in more detail in Chapter 11.

A review of new technologies

O'Reilly introduced the term Web 2.0 technologies to describe the emergence of new open, social and participatory technologies (O'Reilly, 2004; 2005). In particular, the term emphasised a shift from a static Web 1.0 to a Web 2.0 environment that was characterised by user participation. He defined Web 2.0 as a set of principles and practices. The term 'open, social and participatory media' has also been used, emphasising the core characteristics of these new technologies. These characteristics include: users as publishers, harnessing distributed collective intelligence (Lévy, 1997), user-evolving folksonomies (Mathes, 2004; Nozuri, 2006), peer production and critique, the wisdom of the crowds (Surowiecki, 2004), the architecture of participation (O'Reilly, 2004), the notion of the perpetual beta, free tools and resources, and the notion of openness.[11]

The characteristics of new technologies

The characteristics of these new technologies include the following:

- Peer critiquing – the ability to openingly comment on other people's work. This has become standard practice within the blogosphere and is being used in general society. For example a growing number of authors and journalists are now active bloggers and traditional book writing is being supplemented by writers keeping a blog and inviting readers to comment on the evolving plot, by academics (through self-reflective blogs on digital scholarship and research ideas) and by learners (in terms of keeping their own reflective blogs or contributing to a collective cohort blog).
- User-generated content – there are now many different tools for creating content (ranging from those which are primarily text-based, through to rich multimedia and interactive tools), meaning that the Web is no longer a passive media for consumption, but an active, participatory, productive media. Sites such as YouTube,[12] Flickr[13] and Slideshare[14] facilitate sharing of user-generated content and the embedded code functionality means that content can be simultaneously distributed via a range of communication channels.
- Collective aggregation - hierarchy and controlled structures make little sense in an environment that consists of a constantly expanding body of content that can be connected in a multitude of ways. Collective aggregation refers both to the ways in which individuals can collate and order content to suit their individual needs and personal preferences, as well as the ways individual content can be enriched collectively by the wider community (via tagging, multiple distribution, etc.). Social bookmarking, tag clouds and associated visualisation tools, tagging, RSS feeds and embedding code all enable collective aggregation to occur.

---

[11] The notion of openness is discussed in more detail in Chapter 11
[12] youtube.com
[13] http://www.flickr.com/
[14] http://www.slideshare.net/

- Community formation – clearly the connectivity and rich communicative channels now available on the Web provides an environment for supporting a rich diversity of digital communities. Boundaries of professional and personal identity are eroding and the notion of tightly knit Communities of Practice (Wenger, 1998) are giving way to a spectrum of communities from individualistic spaces through loosely bound and often transitory collectives, through to more established and clearly defined communities. See Dron and Anderson (2007) for a more specific discussion of collectives, networks and groups in social networking for e-learning. I will return to the forms of new online communities and interactions in Chapter 14.
- Digital personas – individuals need to define their digital identity and how they 'present' themselves across these spaces (Solove, 2004). The avatars we choose to represent ourselves, the style of language we use and the degree to which we are open (both professionally and personally) within these spaces, give a collective picture of how we are viewed by others.

The impact of Web 2.0 technologies

There is now a growing body of empirical evidence on the impact of Web 2.0 technologies on education; see for example a review of learning 2.0 by Redecker et al. (2009), the use of Web 2.0 in schools (Crook et al., 2008), the NSF task force on Cyberlearning (Borgeman et al., 2008), the most recent Horizon report on future technological trends (NMC, 2011) and the OECD report on 'new millennial learners' (OECD, 2007).

More specifically a number of articles consider the use of these technologies in an educational context (Anderson, 2007; Downes, 2005; Ebner, 2007). Downes describes the change as a shift from the Web being a medium in which information is passively consumed, to a platform, where content is created, shared, remixed and repurposed by users (Downes, 2005). He describes the way blogs and wikis have emerged as a new medium for expression and the development of online communities. Application of these tools, he argues, means that e-learning content is created and distributed in a variety of different ways, enabling more learner-centred approaches. Anderson (2007) considers the implications of these technologies for Higher Education. He argues that Web 2.0 is more than a set of cool technologies, and that they are changing the ways in which people interact. Whilst Ebner (2007) considers the reality behind the hype around Web 2.0 technologies and in particular their advantages and disadvantages.

De Frietas and Conole (2010) also argue that there has been a shift in the use of tools, which emphasises the more participatory and communicative capabilities of new technologies. These enable content and information to be distributed in a variety of different ways and hence the nature of content, both in terms of production and distribution, has shifted with greater control for the individual as producer and user. So whereas initial use of the Web was essentially fairly static with hyperlinked information pages displaying information, Web 2.0 shifts towards a more active and distributed network with user-generated content and a much richer, inter-connected network of communicative channels. They further refine this shift as being about: a shift from information being a scarce, expensive commodity to an abundance of information, challenging traditional notions of authority, and finally that content can be distributed and rendered in multiple ways. They list a number of ways in which these technologies can be aligned with modern thinking about adopting more constructivist and situative learning approaches. Web 2.0 practices enable the shifting of learning from a focus on individual to social learning. Location-aware technologies can enable contextualised and situated learning. The adaptable functionality of Web 2.0 tools means that learners can personalise their learning. Virtual worlds can be used to support experiential and authentic learning, whilst search engines like Google can support inquiry- and resource-based learning. User generated content has resulted in a plethora of Open Educational Resources (OER) now being freely available. And finally tools such as blogs, e-portfolios and online games such as WorldofWarCraft[15] are being used to support peer learning and reflection.

Redecker et al. (2009, p. 19) undertook a review of the use of Web 2.0 technologies in education. They define Web 2.0 as: "the range of digital applications that enable interaction, collaboration and sharing between users". These tools include blogs, wikis, social bookmarking and tagging, media sharing services, podcasts and virtual worlds. Effective use of these tools requires learners and teachers to develop new skills, not only to manage the abundance of information, but also to participate in distributed networks, and to develop critical communicative, collaborative and creative skills.

These tools enable pedagogical innovation through promoting personalisation and collaborative learning and are resulting in a change in the roles of learners and teachers. Redecker et al. (2009) also argue that the lack of widespread take up of these tools can be attributed to a number of barriers, such as: a lack of access to ICT, learners and teachers lacking the necessary digital literacy skills to make effective use of these technologies, a lack of the pedagogical skills needed to design effective learning interventions utilising the affordances[16] of these technologies, as well as concerns over security and privacy.

The use of Web 2.0 technologies in education

Table 1 provides some examples of how Web 2.0 tools are being used in education, including a description, in each case, of the potential impact on education. These indicate that these tools can result in pedagogical innovation in a number of ways. Firstly, by providing new ways of collaborative creation and exchange of learning content. Secondly, by providing new forms of communication amongst learners and teachers. Thirdly, by providing more personalised and learner-centred environments. Fourthly, these are resulting in new forms of blended learning contexts emerging. Fifthly, they are motivational in terms of providing active, discovery-based learning approaches and a sense of learner ownership.

[16] This is discussed in Chapter 6

Scaffolded	VEOU (Wills et al., 2004)	Virtual Continuing Professional Development (CPD) and scaffolded support for publication.	Potential to change the ways in which professional CPD is delivered, offering more tailored, personalised and just-in-time training.
Open	E-Bank – towards truly "Open research", (Coles et al., 2006) MIT OpenCourseWare (http://ocw.mit.edu/)	Access to open learning materials designed to support both learners and teachers.	Democratisation of education in terms of content production and delivery. Wider access to materials for casual learners and to support informal learning as a 'taster' for formal learning qualifications.
Cumulative	CCK09 (Siemens, 2009) - A free online course	An experimental course in which both the content and expertise is free. This kind of course is commonly referred to as a Massive Online Open Course (MOOC).	What is the role of traditional educational institutions in a world in which content and expertise is increasingly free?
Social	Cloudworks (Conole and Culver, 2009, 2010)	Social networking for an educational context.	Social networking applied to education has the potential to change the ways in which teachers exchange information; with the potential to lead to proactive sharing and reuse of educational resources.
Authentic environments	WISE project – (SecondReiff Aachen School of Architecture); Stanford Medical School simulations using the Olive platform (cited in Ala-Mutka et al. 2009)	Authentic real-time modelling environment in Second Life for Architecture and medical students.	Scope for training in new and realistic environments. Pedagogical models include exploratory learning (ELM), inquiry learning and problem-based learning approaches.
Fostering inquiry learning	The Personal Inquiry Project (Sharples and Scanlon (Eds), 2011)	Development of inquiry-based learning skills for students to enhanced their understanding of science.	Through independent learning approaches, peer learning is encouraged and analytical skills may be fostered.

Enhancing life experiences	Mundo des estrellas (cited in Ala-Mutka et al. 2009) JISC MyPlan project, http://www.jisc.ac.uk/whatwedo/programmes/elearningcapitcal/xinstit1/myplan.aspx	Young people in hospitals, interactive gaming, life swapping and sharing of experience. The MyPlan project provided tools for lifelong career decisions and educational choices using visualisation of learners' timelines www.lkl.ac.uk/research/myplan.	The potential for these tools to support lifelong learning opportunities and enhance life experiences.
Broadening access	Notschool and Schome projects (cited in Ala-Mutka et al. 2009)	Notschool for virtual home schooling for disaffected children and Schome project for gifted and talented kids.	The impact of this includes outreach to children and excluded, talented learners. Using familiar media-based metaphor,s rather than traditional school-based metaphors, new learners may be reached.
New forms of collaboration	CSCL (Computer Supported Collaborative Learning) pedagogical patterns (Hernández et al., 2011)	Structured pedagogical patterns to support different forms of collaborative activities.	Broader application of pedagogical patterns and other scaffolded forms of pedagogy have the potential to transfer good practice from research into practice in an effective way. Automation of such patterns can be embedded in pedagogy tools.
Co-construction of understanding	Wlker's Wikinomics (cited in Ala-Mutka et al. 2009), The Decameron Web ((http://www.brown.edu/Departments/Italian_Studies/dWeb/dWeb.shtml)	Collaborative co-construction of understanding of Economics. An interactive online text.	Blurring research and teaching: examples of how the Web can provide access to scholarly materials and give students the opportunity to observe and emulate scholars at work.
Aggregating and sharing content	Wikipedia	Co-construction of knowledge through collaboration and iterative development.	New tools provided for learners at all stages, and interaction between learners and publication of shared knowledge.

The examples cited in Table 1 demonstrate the rich ways in which technologies can be used to support learning; in terms of enabling new forms of communication, collaboration and co-construction of knowledge, aggregation of resources, supporting different forms of pedagogy, and providing authentic environments for role-based learning.

Impact on practice

Conole (2009) synthesises some of the characteristics that define these new technologies and lists their impact on practice (both positive and negative). These include: the impact of free tools, resources and services, ubiquitous access, multiple communication and distributions channels, media rich representations, user-generated content and social profiling. This section will describe each of these in turn. Table 2 summarises the characteristics of new technologies and their potential positive and negative impact.

The Internet has enabled access to a vast amount of information and with the growth of the Open Educational Resource movement (Atkins et al., 2007), access to free resources. However finding appropriate resources and knowing how to use them is a specialised skill. Many learners, despite being competent technology users, lack the appropriate academic literacy skills to appropriate these free resources for their learning (Jenkins et al., 2006; Jenkins, 2009; Lankshear and Knobel, 2006). McAndrew et al. (2008) considered Web 2.0 characteristics and compared them against the way in which Open Educational Resources (OER) are developed and used, drawing on evaluation data on the use of the Openlearn site.[17] For example, they argue that such sites align well with the long-tail phenomenon (Anderson, 2004) by providing access to specialist subjects. Similarly, the social tools associated with the site enable users to contribute ideas and adapt content providing an example of the Web 2.0 user-generated content and the broader notion of users adding value within a Web 2.0 context. The availability of free tools means that students can appropriate and personalise these for their individual learning needs. However there is a tension between these tools and those under institutional control. If students are able to use free email tools, wikis, blogs, etc – what is the function of an institutional Learning Management System (LMS) and what, if any, tools and services should institutions be providing? See Al-Zoube (2009) for a discussion of e-learning in the cloud.

Web 2.0 practices relie on scale; both in terms of access to a vast array of user-generated content and through harnessing the power of the collective - the so called notion of ‘the wisdom of the crowds’ (Surowiecki, 2004). Such scale requires easy access and in this respect, in the development world at least, we are approaching a state of near ubiquitous

[17] http://openlearn.open.ac.uk

access, with wifi almost universally available, the percentage of those online is approaching 100% in most developing countries, however the digital divide is still evident – narrower but deeper (Warschauer, 2004). Warschauer critiques the relationship between access to information and communication technologies and social inclusion. He argues that: “the ability to access, adapt and create new knowledge using new information and communication technologies is critical to social inclusion in today’s era” (Warschauer, 2004, pg. 9).

The variety of communicative channels and multiple distribution mechanisms for retrieving and aggregating information means that there are a multitude of opportunities for finding resources and communicating with peers or experts. However, this has also led to a ‘fragmentation of voice’ – there is no longer one definitive source of knowledge, no one ‘expert’. Learners need to develop strategies for finding and validating appropriate resources. Learners and teachers have a variety of communicating channels (email, chat, blogs, audio and video conferences, social networking sites, etc.), there is no single communicative channel. This multiplicity can be confusing and disorientating for both learners and teachers.

The richness of the new media means it is possible for new forms of representation, providing new opportunities in terms of sense-making (Okada et al., 2008), but raises issues in terms of whether students and teachers have the appropriate digital literacy skills to utilise these representations (Seely Brown, 2006).

The user participation and social practices of Web 2.0 technologies clearly provide immense opportunities in terms of fostering collaboration and for co-construction and sharing of knowledge, but raise a number of issues about quality, copyright and privacy. Table 2 summarises the positive and negative impacts of the different characteristics of these new social and participatory technologies.

Change	**Positive impact**	**Negative impact**
Free tools, resources and services	Specialised niche use, access and personalisation	Inappropriate academic literacy skills. Lack of institutional control
Ubiquitous access	Technology as a core tool for learning	Narrower, but deeper digital divide
Multiple communication and distribution channels	Increased opportunity for peer and tutor dialogue. Information repurposed to meet different needs	Fragmentation of voice. No centralised repository of knowledge
Media rich representations	New forms of sense-making	Lack of new forms of digital literacy
User-generated content and social profiling	Variety and acknowledging individual contributions. Knowledge sharing and community build	Quality assurance issues. Inappropriate descriptions and use of personal information for other purposes

Table 2: Characteristics of new technologies and impact on practice

A review of Web 2.0 tools and practice

Conole and Alevizou (2010) undertook a review of the use of Web 2.0 technologies in education, building on the review by Redecker et al. (2009). They focussed in particular on the use of these tools in Higher Education. They adapted a taxonomy of types of the types of Web 2.0 tools developed by Crook et al. (2008) based on the functionality of different tools:

- Media sharing – creation and exchange of media with peers.
- Media manipulation and data/Web mash ups[18] – tools to design and edit digital media files and combine data from multiple sources to create a new application, tool or service.
- Instant messaging, chat and conversational areas – to enable one-to-one or one-many conversations.
- Online games and virtual worlds – rule-governed games or themed environments.
- Social networking – enabling social interactions between friends and peers.
- Blogging – where users can post text that others can comment on.
- Social bookmarking – aggregation and tagging of Web resources.
- Recommender systems – that aggregate and tag user preferences and make recommendations.
- Wikis and collaborative editing tools – where users can collaboratively create, edit and link pages.
- Syndication – where users can subscribe to RSS feed-enabled Websites.

Jenkins et al. (Jenkins, et al., 2006; Jenkins, 2009) argue that a new set of digital literacies are needed for learners and teachers to be part of what they describe as this new ‘participatory culture’. These are: play, performance, simulation, appropriation, multi-tasking, distributed cognition, collective intelligence, judgement, transmedia navigation, networking, negotiation and visualisation. Similarly, Beetham et al. (2009) provide a comprehensive framework of new literacies relating to social and situated practice. These include: meaning making and situated knowledge, technological and media literacies, and scaffolded and metacognitive literacies. They argue that today’s learners need to develop the following capabilities: managing work/life balance, social entrepreneurialism, development and projection of identities, communicating and collaborating across national and international boundaries, contributing to knowledge and understanding in hybrid networks of people and non-human cognitive agents, managing career and

[18] A mashup is a Web pageor application that uses and combines data, presentation or functionality from two or more sources to create new services.

learning paths, exercising judgement, acting ethically, reflecting/planning/seeking support from others, assessing and addressing threats, and exercising multiple modes of meaning making.

Conole and Alevizou provide a description of the ways in which Web 2.0 technologies are being used to support learning and teaching and how these relate to different pedagogical approaches. An adapted version of this is shown in Table 3. What is evident is that the characteristics of Web 2.0 technologies appear to align well with modern pedagogical good practice in terms of promoting constructivist and situative approaches to learning. De Freitas and Conole (2010, p. 19) argue that:

> The description above paints a picture of a rich and exciting technological environment to support learning; with a multitude of mechanisms for: rendering content, distributing information and communicating. There seems to be a tantalising alignment between many of the social capabilities of the tools and practices evident with new technologies and what has emerged as 'good' pedagogy in recent years.

Table 3: Mapping of Web 2.0 tools to different pedagogical approaches

Pedagogical approaches	Web 2.0 tools and approaches	Examples
Personal learning	The ability to adapt, customised and personalise, use of RSS feeds, mash ups and APIs	The digital learning communities project (http://www.thedlc.org/).
Situated learning, experiential learning, problem-based learning, scenario-based learning, role play	Use of location-aware functionality, immersive 3D-worlds, use of search engines and other online resources as sources of evidence, connection with peers and experts via social networking tools, scenario-based and authentic tasks in virtual worlds, application of gaming technologies for educational purposes	The iCamp project, use of SecondLife to support different disciplines (http://www.icamp.eu/) Cyberone law role-play (Rooney, 2007)
Inquiry-based learning, resource-based learning	Tools to support user-generated content and facilitating easy sharing and discussion, media repositories (Flickr, YouTube, and SlideShare), social bookmarking sites (Delicious), digital repositories and tools for content generation, use of search engines, participation in distributed virtual communities, use of folksonomies and social book marking as mechanisms for finding and organising resources	The Open Educational Resource movement and associated tools and repositories, like OpenLearn.

Reflective and dialogic learning, peer learning	Tools for fostering peer reflection such as blogs and e-portfolios, commenting on other learners' blog posts, co-creation of learning artefacts in wikis	Digital learning communities (http://www.thedlc.org/) The peer-to-peer mentoring framework
Communities of Practice	Use of social networking tools to participate in communities of learning and/or teaching	Application of tools such as Facebook, Ning and ELGG to support informal social interactions between learners and as spaces for reflection on professional practice around shared interests, for example the ELESIG community in Ning (http://elesig.ning.com)
Scholarly practice and the sharing of designs and good practice	Use of Web 2.0 technologies to participate in a distributed network of educators and researchers. Use of blogs, Twitter and wikis to co-create knowledge and understanding, to critique practice, and to share professional practice and resources	Edublogs (http://edublogs.org/), LeMill (http://lemill.net/), Cloudworks (http://cloudworks.ac.uk)

Learning spaces

A number of researchers are now exploring what new forms of learning spaces might be needed to effectively use new technologies in a blended learning context. For example, the Spaces for Knowledge Generation (SKG) project,[19] which aimed to inform, guide and support sustainable development of learning and teaching spaces and practices. It was influenced by constructivist approaches and aimed to design new learning spaces and use of technologies that fostered more learner-centred approaches to learning. In contrast, Cummings (2011), focussed on the kinds of the learning spaces that might be needed to promote experiential learning.

Boys (2010), looks at how learning spaces can be used to foster creativity. She argues that we need to rethink the architecture of educational spaces and that this will challenge some of the perceived wisdom of existing learning spaces. See also the 'spaces for learning in art and design' blog,[20] which is a collective set of resources on learning spaces.

[19] http://www.skgproject.com/
[20] http://www.spacesforlearning.blogspot.com/

In the UK, the Joint Information Systems Committee (JISC) undertook a programme of work around learning spaces (JISC, 2006). In the introduction to the report it is argued that:

> Learning is changing in the 21st century. Technologies used in learning, such as interactive whiteboards, personal learning environments, wireless networks and mobile devices, plus the internet and high-quality digital learning resources – and the ability to access many of these from home and the workplace – are altering the experiences and aspirations of learners

The focus of the report is the need for more cost effective use of spaces and the creation of technologically rich learning spaces. Factors of importance included: motivating learners, encouraging collaboration, supporting personalisation and inclusion, and enabling flexibility. The report reviews different examples of learning spaces, to support formal, informal and non-formal learning. These include: effective use of entrances, teaching spaces, learning centres and social spaces.

Conclusion

As the examples in this chapter demonstrate, Web 2.0 tools have much to offer for learning and teaching and can be used in different ways to support a wide range of pedagogical practices. However, despite pockets of good practice, on the whole Web 2.0 technologies have not being taken up extensively in learning and teaching. Therefore a number of challenges remain in terms of their use. These include the changing nature of learning and teaching in such spaces, the new media, information and networked literacies needed, the need for a better connection between research on the use of these tools and associated policy and practice, and the challenges with trying to change existing practice, to get learners and teachers to adopt more open approaches.

Conole and Alevizou (2010) argue that effective use of new technologies requires a radical rethink of the core learning and teaching processes; a shift from design as an internalised, implicit and individually crafted process to one that is externalised and shareable with others. They argue that change in practice may indeed involve the use of revised materials, new teaching strategies and beliefs – all in relation to education innovation.

The use of these technologies has significant implications for learners, teachers and educational institutions. Sharpe et al. (2010) provide a summary of recent research looking at the ways in which learners are using and perceiving new technologies. The research indicates that learners are changing, in terms of how they interact with technologies and how they are using them to support their learning. Learners are adopting more social, participatory and just-in-time learning practices; using search engines to find relevant resources and communicating and collaborating though a variety of mechanisms. Much of the research suggests that they are adopting more problem-based and experiential learning. However a note of caution is also needed; although good learners are using these tools effectively, weaker learners struggle to make sense of the vast array of tools and resources at their disposal. Arguably they need guided learning pathways and support to use these effectively to support their learning.

Despite significant investment in promoting the use of technologies in education, use by teachers is far from ubiquitous. Certainly teacher roles are changing as a consequence of the introduction of new technologies and arguably the boundaries between teachers and learners is blurring. However there are a number of barriers to the increased uptake of technologies. Firstly, teachers lack the necessary skills to design and support learning with new technologies. Secondly, there is a tension between their role as researcher and their role as teacher, with research more often than not being privileged over teaching. Finally, they also cite a lack of time and support as barriers to experimenting with new technologies.

Finally, the increased use of technologies has a number of implications for institutions. Firstly, in terms of the types of support needed to enable learners and teachers to use new technologies. Secondly, most institutions are working with legacy systems, which are fundamentally at odds with these new approaches. There is a tension between in-house systems and Learning Management Systems (LMS) and freely available Web 2.0 tools and services (Craig, 2007; Sigala, 2007). The nature and structure of educational institutions is also under threat. In a world where tools and resources are increasingly free, what is the role of a traditional institution?

Despite the hype and rhetoric, Web 2.0, and more specifically learning 2.0, has not yet penetrated mainstream education. Nonetheless the affordances[21] of Web 2.0 technologies and analysis of how they are beginning to be adopted in educational contexts, suggest they could have a profound impact in the near future and that there are a number of potential side effects of the increased use of Web 2.0 technologies, which we need to be aware of. For example, as discussed in this chapter, there are issues in terms of equity of access and the new digital literacy skills needed to make sense of these new digital spaces.

This chapter has considered the characteristics of new technologies and their impact on both organisations and individuals within an educational context. It has argued that there are significant implications for both learners and teachers. At the institutional level, there is little evidence that there is a corporate understanding of these tools either and there is the lack of vision for how social computing can be used. Policies on the use of Web 2.0 technologies are generally inadequate and there is a lack of appropriate training and support to migrate towards greater usage of these tools.

What is evident is that uncertainty and change are the norm; it is clear that we are now working in an environment of constant flux, where the future is unpredictable and where changes appear to be ever more rapid and fundamentally radical in terms of their implications. No one individual can be an expert in all the tools and the potential ways in which they can be used; the approach needs to shift to harnessing the networked aspects of new technologies, so that individuals foster their own set of meaningful connections to support their practice; whether this is a teacher in terms of connections to support them to develop and deliver their teaching or a learner in terms of connections to support and evidence their learning.

---

[21] The concept of affordances is discussed in Chapter 6

The implications of these new technologies for learning and teaching are profound. Unintended consequences (Beck, 1992) of use will arise, misuse and abuses of the system will happen, the digital divide is still present; those not engaging with technologies are getting left further and further behind. Virilio (1998) goes further and suggests that we are utterly dependent on technologies and when (not if) technologies fail it will have a catastrophic effect.

This chapter has argued that a range of new skills are needed; for learners, teachers, support staff and policy makers. Skills to enable them to navigate through and make sense of these new digital spaces, skills to cope with change and the exponential development of new tools, skills to deal with new notions of space, time and boundaries, and skills to cope with a multi-faceted and fast moving environment. We have to accept that it is impossible to keep up with all the changes, so we need to develop coping strategies which enable individuals to create their own personal digital environment of supporting tools and networks to facilitate access to and use of relevant information for their needs. These skills are needed across the range of stakeholders involved in education from students to senior managers; not just a selective minority. The ultimate goal has to remain harnessing the potential of these technologies to provide better and more engaging learning environments and opportunities for learners.

Chapter 5 – Mediating Artefacts

Introduction

This chapter will introduce the concept of Mediating Artefacts, which is one of the key principles underpinning the Open Learning Design Methodology described in this book. It will outline the background to the concept and give examples of the ways in which it can be used to understand the characteristics of technologies. It will describe how the origins of the concept are grounded in a socio-cultural perspective and will discuss how it is used specifically in the area of learning design. Illustrative examples will be provided of the different Mediating Artefacts practitioners use to guide their design process.

The origins of the concept of Mediating Artefacts

The concept of Mediating Artefacts is very much grounded in a socio-cultural perspective, linking back to the work of Vygostky (1962; 1978) and Leontiev and Luria (Leontiev, 1978, 1989; Luria, 1976) and more recently the body of knowledge about

Activity Theory (Cole et al.., 1997; Daniels et al., 2007; Engeström, 2001; Engeström et al., 1999).

Central to Vygotsky's ideas is the notion that social interactions play a fundamental role in the process of cognitive development. Vygotsky argued that what distinguishes humans from other animals is their use of speech in relation to practical activity (Vygotsky, 1978). He argued that words can shape an activity into structure. He described the analogy of signs as tools. Signs can be used as a means of solving a given psychological problem (to remember, compare, report, choose, etc.) and he argued this is analogous to the use of tools. Therefore, signs act as an instrument of psychological activity in a manner analogous to the role of a tool in labour. He referred to this as sub-categories of Mediating Artefacts (Figure 1). He argued that a tool's function is to serve as a conductor of human influence on the object of activity; i.e. it is externally orientated. Whereas a sign changes nothing in the object of psychological operation, it is internally orientated. Therefore humans use tools that are developed from a culture, such as speech and writing, to mediate their social environment.

Figure 1 shows the two types of Mediating Artefacts, namely tools and signs. A fundamental premise of Vygotsky's theory is that tools and signs are first and foremost shared between individuals in society and only then can they be internalised by individuals. Vygotsky argues that:

> Every function in the child's cultural development appears twice: first, on the social level, and later, on the individual level; first, between people (interpsychological) and then inside the child (intrapsychological). This applies equally to voluntary attention, to logical memory, and to the formation of concepts. All the higher functions originate as actual relationships between individuals (Vygotsky, 1978, p. 57).

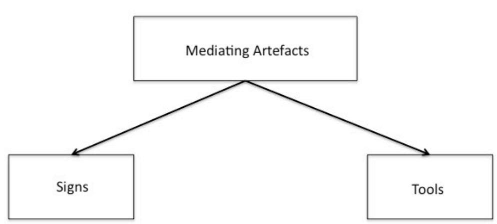

Figure 1: Signs and tools as Mediating Artefacts

Building on this he introduced the concept of the 'Zone of Proximal Development (ZPD)' which he defined as:

> We propose that an essential feature of learning is that it creates the zone of proximal development; that is, learning awakens a variety of internal development processes that are able to operate only when the child is interacting with people in his environment and in cooperation with his peers. Once these processes are internalised, they become part of the child's independent developmental achievement (Vygotsky, 1978, p. 90).

In other words, the Zone of Proximal Development is the difference between what a learner can do without help and what they can do with help from others. The concept of scaffolding (Wood at al., 1976) builds on this idea and relates to the idea of the teacher providing scaffolding to the learner's ZPD, which is then faded over time as the learner becomes more competent.

Capturing and representing practice

Conole (2008) describes how the concept of Mediating Artefacts can be adapted and used in a learning design context. An important aspect of learning design is the process of eliciting a design describing the essence of a learning activity that can then be reused in the development of a new learning activity. Central to this is the fact that we want to abstract the essential and transferable properties of learning activities, i.e. we want to abstract and describe those properties that are effective, but that can also be applied to other contexts, those properties that are not context bound to a particular instance of activity.

Learning activities can be 'codified' into a number of different representations; each one foregrounds different aspects of the learning activity and provides a means of illustrating the inherent design underpinning the learning activity. These forms of representation are defined here as Mediating Artefacts because this emphasises their mediating role in terms of how they are used to mediate design activities. Course designers use a range of Mediating Artefacts (MAs) to support and guide decision making; ranging from rich contextually located examples of good practice (case studies, guidelines, etc.), to more abstract forms of representation which distill out the 'essences' of good practice (models or patterns). In the context discussed here, I argue that Mediating Artefacts can be derived from existing learning activities by a process of abstraction (Figure 2). The same Learning Activity (LA) can result in a range of abstractions:

- Textually based narrative case studies, describing the key features of the Learning Activity and perhaps barriers and enablers to its implementation.
- More formal narratives, against a specified formal methodology such as a pedagogical patterns (Goodyear, 2005; Goodyear and Retalis, 2010).
- Visual representations, such as a mind map or formalised UML[1] use case diagram.
- Vocabularies (Currier et al., 2005), such as taxonomies, ontologies or folksonomies.
- Models (Conole, 2010; Mayes and De Freitas, 2004), foregrounding a particular pedagogical approach (such as instructivism, problem-based learning or an emphasis on

[1] http://www.uml.org/

a dialogic or reflective approach).

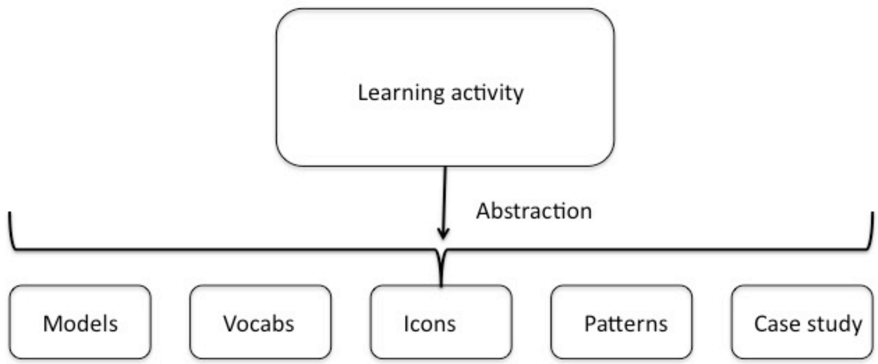

Figure 2: The range of Mediating Artefacts that can be derived from a learning activity

Mediating Artefacts help practitioners to make informed decisions and choices in order to undertake specific learning and teaching activities. They differ in a number of respects: i) their format of presentation (textual, visual, auditory or multimedia), ii) their degree of contextualisation (ranging from abstract to fully contexualised), iii) the level of granularity (i.e. the amount of details available within the MA about the learning activity), and iv) the degree of structure (flat vocabularies verses typologies).

Examples of Mediating Artefacts

Narratives or case studies provide rich contextually located MAs, which are valuable in that they describe the details of a particular pedagogical intervention. The drawback is that because they are so contextually located they may be difficult to adapt or repurpose. Pedagogical patterns provide a specifically structured means of describing practice, building on the work of the architect Alexander (Alexander, 1977; Alexander et al., 1977), by presenting the LA in terms of a problem to be solved, see for example Goodyear (2005) and Goodyear and Retalis (2010) and the Pedagogical Patterns project.[2]

Vocabularies represent a more ‘atomistic’, text-based form of representation by describing the components involved in learning activities. Currier et al. (2005) provide a review of educational vocabularies to describe practice and curriculum design which goes beyond the description of resources, focusing at the level of learning activities. They

[2] http://www.pedagogicalpatterns.org/

consider the range of vocabularies that have been developed to describe practice, including an inventory of existing pedagogical vocabularies, such as flat lists, taxonomies, thesauri, ontologies and classification schemes. Conole (2008) articulates the components of a learning activity. These include the context within which the activity occurs (subject, level, etc.), intended learning outcomes associated with the activity mapped to Bloom's taxonomy (Anderson and Krathwohl, 2001; Bloom, 1956), the pedagogical approaches, the tasks the learners are required to do in order to achieve the learning outcomes, and any associated assets and outputs (tools, resources, support or outputs). This has been adapted from a taxonomy developed in previous work (Conole, 2007). Table 1 shows the components of the learning activity taxonomy. This includes a list of possible pedagogies, including approaches and techniques, as well as the tasks, tools, resources, support and outputs. This can be used as a checklist in the design process helping to identify and consider each of the components involved in a learning activity and serves to illustrate the variety of factors which constitute a learning activity, further demonstrating the complexities involved in the design process.

Context	Learning outcome, subject, discipline, level, learner characteristics, pre-requisites, time to complete

Table 1: The learning activity taxonomy

Diagrammatic or iconic presentations are important as they give a quick overview of the key features of an activity. They are valuable in that they can emphasise different connections between aspects of the activity, give an indication of structure and a sense of flow or movement. Learning activities can be represented visually adopting a particular iconic representation (Botturi et al., 2006; Botturi and Stubbs, 2008). Examples of these include the formal visual presentations used for Unified Modeling Language (UML)[3] use cases (see for example Van Ed and Koper (2006)) or the approach adopted by the AUTC Learning Design project (Agostinho, 2006; Agostinho et al., 2002). In the AUTC learning design representation, learning activities are broken down into a series of tasks which learners undertake, alongside these associated resources and support are illustrated. In addition to this visual 'temporal sequences' for each learning activity there is a rich range of additional information about the design process. As described in Chapter 8, we have developed a particular iconic representation that adopts a similar approach to these (Conole, 2007; Conole et al., 2008) focusing on a set of tasks adopted by each 'role' in the learning activity and an associated set of resources and tools. Tools, resources and outputs associated with each task are shown alongside, with arrows indicating connections.

Models provide more abstract forms of representation. Simplistically, a model is an abstract representation that helps us understand something we cannot see or experience directly. Beetham considers a model to be 'a representation with a purpose' with an intended user, and distinguishes five usages of the word: 'practice models or approaches', 'theoretical models', 'technical models', 'models for organisational change', and 'students' models' (Beetham, 2004). Models are usually aligned to a particular pedagogical approach. Examples of learning models frequently used in e-learning include: Kolb's learning cycle (Kolb, 1984), Laurillard's conversational framework (Laurillard, 2002), Salmon's e-moderating framework (Salmon, 2003) and Wenger's Community of Practice model (Wenger, 1998). See Chapter 14 and Conole (2010) for more details on these. Each emphasises different aspects of learning. Kolb presents an action-based or 'learning by doing' model through a four-stage cycle (experience, reflection, abstraction and experimentation). Laurillard describes the stages involved in the dialogic interaction between a learner and teacher, demonstrating the way in which concepts are internalised and adapted by each in the process. Salmon's five-stage framework for supporting effective e-moderating in discussion forums, emphasising the dialogic aspects of socially situated theoretical perspectives. Finally, although not originally developed for a learning context but now widely used in e-learning, Wenger's theory of Communities of Practice is valuable as it considers the ways in which Communities of Practice are formed, developed and fostered. He sees four main aspects: learning as community; learning as identity; learning as meaning; and learning as practice. Therefore each is valuable in that it helps to foreground particular aspects of learning, which can then be used to provide guidance.

---

Understanding learning activities through Mediating Artefacts

Using the concept of Mediating Artefacts enables us to foreground the different aspects of a learning activity that a particular representation highlights. MAs have different strengths, weakness and purposes, depending on the context of use and the configurations of their affordances[4] and their constraints. For example, narratives and case studies provide rich contextually located Mediating Artefacts that are valuable in that they describe the details of a particular pedagogical intervention. The drawback is that because they are so contextually located they may be difficult to adapt or repurpose. Models and patterns provide more abstract forms of representation. However, because by their nature they are abstractions, practitioners may misunderstand how to effectively apply a model or pattern and hence as a result adopt a surface application of the model to their practice. Patterns are narratives, but are grounded in a particular way of thinking which emphasises a problem-based approach to design.

Agostinho rightly notes that there is currently no consistent notation system for learning design (Agostinho, 2006). The Mod4L project[5] identified a range of representations that practitioners use to represent practice (Falconer and Littlejohn, 2006), including: taxonomies and matrices, visual presentations (flow diagrams, mind maps), case studies and lesson plans. The project used these with practitioners in a series of workshops to identify their usage and perceived value. They concluded that use is complex and contextualised and that no one presentation is adequate. This aligns with the arguments being made here; by identifying and labelling Mediating Artefacts we are able to understand how learning activities are being represented and how these artefacts might be then used in a mediation role to guide new design.

Meta-Mediating Artefacts

Figure 3 shows how existing learning activities can be repurposed to create a new learning activity. The essence of a LA is abstracted into a MA; different MAs highlight or foreground different aspects of the LA. Mediating Artefacts can also be aggregated to provide more structured or scaffolded support, for example in the form of interactive toolkits, planners or repositories (for example a library of cases studies). So, for example, a model, case study or pattern can become part of a repository, which may consist of similar examples or might be a mixture of models, case studies and patterns. Case studies and models might be combined with some supporting text to form a pedagogical planner or an interactive toolkit. Video clips, case studies, models and patterns might be reviewed and key points synthesised and put into a set of tips and hints or guidelines. Lever (2006) discusses a range of different meta-Mediating Artefacts and compares seven examples, which he terms ‘educational galleries’: Contemporary Online Teaching Cases (COTC),[6] Designing Electronic Learning and Teaching Approaches (DELTA),[7]

[4] The concept of affordances is described in Chapter 6
[5] http://www.academy.gcal.ac.uk/mod4l/
[6] http://www.deakin.edu.au/itl/teach-learn/cases/
[7] http://Webct.med.monash.edu.au/muso.html

DesignShop (DS),[8] DialogPlus Toolkit (DPT),[9] Learning Designs (LD),[10] Teach with Technology (TwT)[11] and UMUC-Verizon Virtual resource site for teaching with technology (UMUC).[12] Figure 3 illustrates the role of Mediating Artefacts and Meta-Mediating Artefacts in the design of a new learning activity. It shows how a new LA can be constructed either from an individual Mediating Artefacts (such as a case study, model or iconic representation) or from a Meta-Mediating Artefact (such as a toolkit). The figure illustrates the process of abstracting learning activities into Mediating Artefacts that can then be used in the construction of a new learning activity.

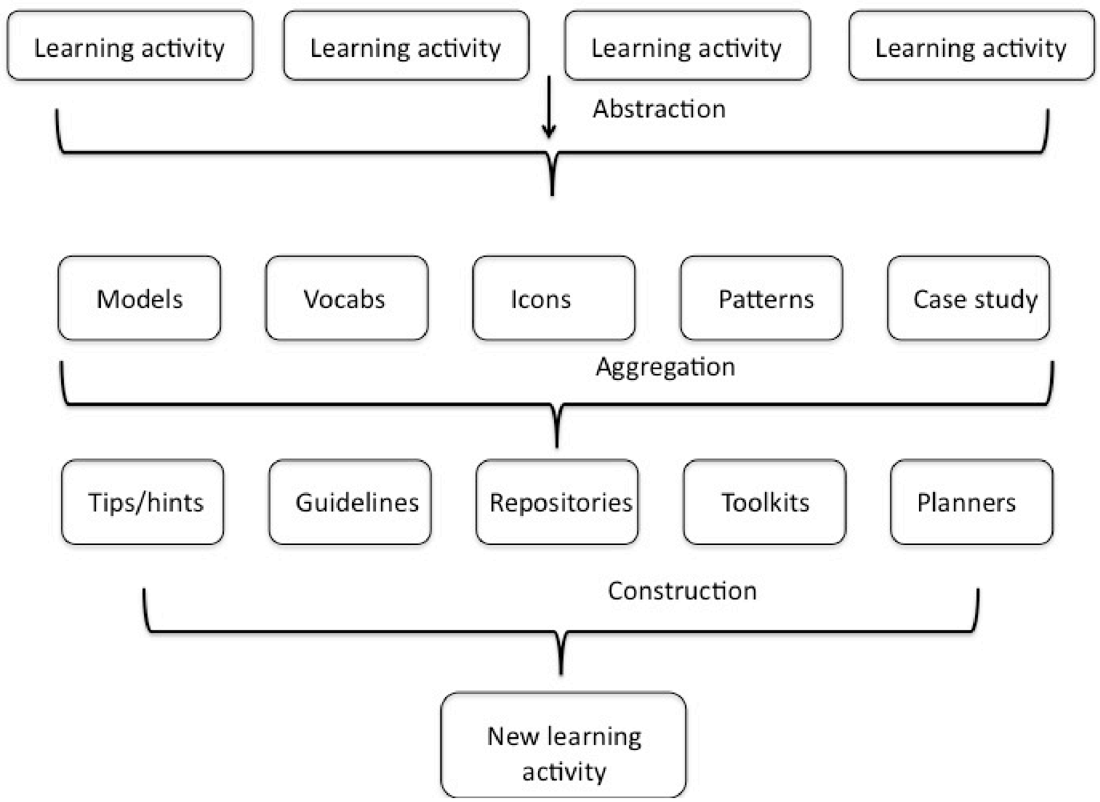

Figure 3: Mediating Artefacts, Meta-Mediating Artefacts - abstraction, aggregation and construction

Therefore, Mediating Artefacts can be aggregated into meta-Mediating Artefacts of three main kinds:

---

[8] http://www.edtech.vt.edu/edtech/id/index.html
[9] http://www.nettle.soton.ac.uk/toolkit/
[10] http://learningdesigns.uow.edu.au/
[11] http://dmc.umn.edu/teach.shtml
[12] http://www.umuc.edu/virtualteaching/

- Aggregates**.** The first type consists of aggregates of example MAs, for example repositories of case studies, patterns or models or a combined repository containing a mixture of all three.
- Scaffolds**.** The second type consists of scaffolds of some kind, that synthesise key points and issues, for example tips and hints or guidelines.
- Mixed**.** The third type consists of a mixture of example MAs and scaffolds or supporting text, such as toolkits and pedagogical planners (as discussed in Chapter 10).

Examples of meta-Mediating Artefacts associated with learning activities and learning design include the:

- OTIS repository of case studies[13]
- e-learning centre library of case studies[14]
- series of effective practice guides and case studies produced by JISC,[15] which synthesise key features across their development programmes
- AUTC learning design Website[16]
- MERLOT database of resources and associated support[17]

This section has argued that by defining forms of representation which aim to describe aspects of a learning activity as Mediating Artefacts this helps to: foreground what each MA offers, ground this in a socio-cultural perspective emphasising the mediational role of such artefacts in the design process and contextualising this alongside other aspects involved, and enables us to see the full cycle of abstraction and construction of learning activities and how Mediating Artefacts are used in the process.

Activity Theory

The concept of Mediating Artefacts as described in this chapter derives from a socio-cultural perspective. This perspective recognises that learning activities are contextually bound. Use of an Activity Theory lens is valuable as it helps to highlight the relationship between the different components involved in the design process, as well as the context within which it takes place.

Kaptelinin and Nardi provide a comprehensive overview of Activity Theory and its origins (Kaptelinin and Nardi, 2006). Also see (Cole and Engeström, 1993; Daniels, et al., 2007; Engeström, 2001; Engeström, et al., 1999; Kuutti, 1996; Nardi, 1995). A key idea in Cultural Historical Activity Theory (CHAT) is the notion of mediation by artefacts (Kuutti, 1996), which are broadly defined to include instruments, signs, language, and machines (Nardi, 1995).

[17] http://www.merlot.org

Mediating Artefacts can support learners and teachers in making the best use of tools and resources. They mediate between the user and the end goal, as illustrated in Figure 4. They enable the user to elicit and represent the inherent designs associated with a particular learning activity or resource. The vision is that if these designs can be abstracted and represented in a meaningful and understandable way, there is a greater chance of them being picked up, used and adapted by others, which, in turn, over time, is likely to lead to an evolving understanding of how new tools and resources can be used.

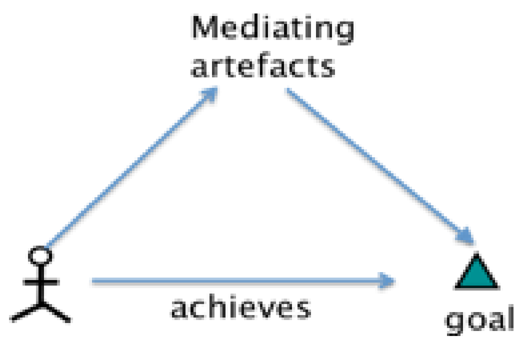

Figure 4: Representation of the relationship betweeen Mediating Artefacts, the use and the intended goal

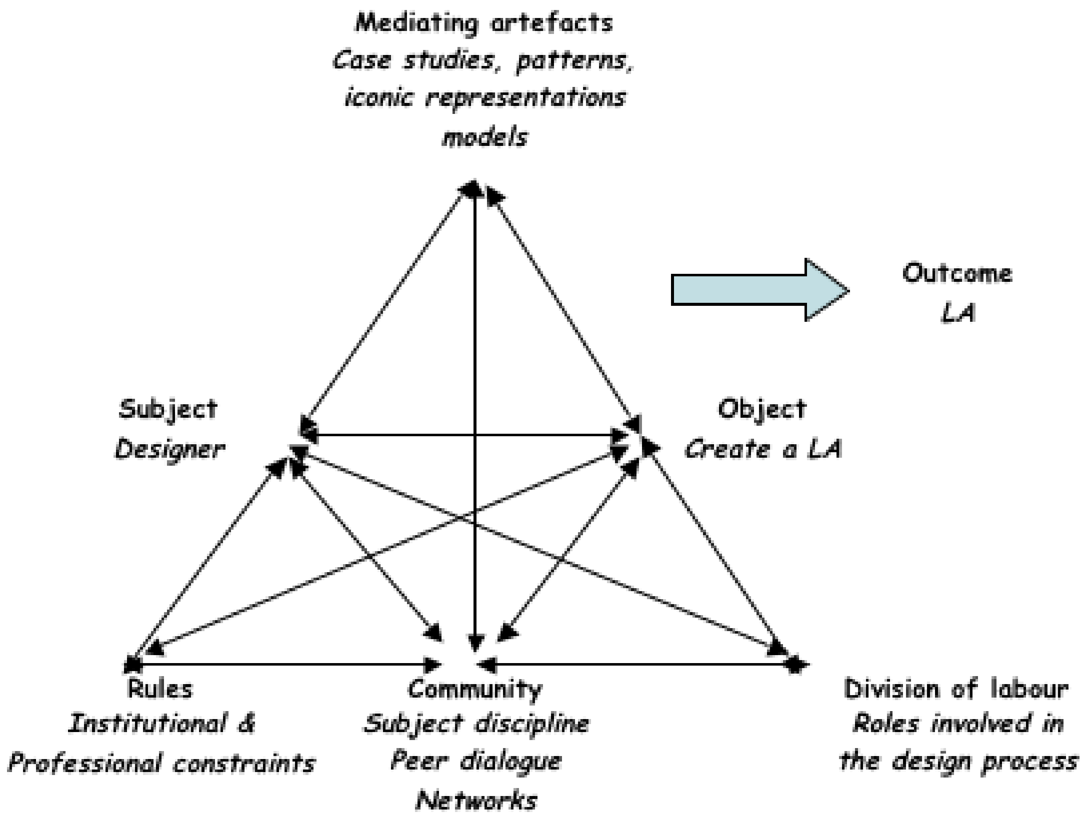

Figure 5: An Activity Theory representation of the learning design process

Figure 5 locates a Mediating Artefact within a CHAT framework. The subject is the designer involved in creating a learning activity. The object therefore is the motivation to design a learning activity and the outcome is the designed learning activity. The process can be mediated by a range of Mediating Artefacts as described earlier. The use of CHAT enables us to describe the context within which this process occurs. The design process will involve a number of roles (division of labour). At the simplest level, this may consist of an individual teacher working alone to create a learning activity. However, the design process may be team-based, in which case different individuals might adopt different roles (e-learning advisor, facilitator, evaluator, etc.) or it might be a teacher working in conjunction with an educational developer or an instructional designer. The rules help to contextualise the creation of the learning activity. They include rules and constraints that bound the design process – for example the institutional context, professional constraints and requirements, local practices and processes. Finally, the community node helps to identify the range of dialogic mechanisms that are used in the design process. These are important because they provide the designer with flexibility as they provide an opportunity to clarify and discuss issues around the creation of a learning activity in further detail. In a series of interviews with course designers, this dialogic process was cited as one of the most important mechanisms for guiding practice. See Cross et al. (2008) and Wilson (2007) for a description of these case studies.

The learning activity produced as a result of this process can then be represented in a number of different forms of representations that can in turn act as Mediating Artefacts in the creation of new learning activities (Figure 6). The CHAT triangle on the left illustrates the creation of a learning activity LA_1 using a Mediating Artefact MA_1. The Learning Activity, LA_1 can then be represented in a number of forms of representation (MA_2, MA_3 and MA_4 – which might be narrative cases studies, an iconic representation, a video clip or a schematic model), which are in turn used as starting points in the creation of new learning activities (LA_2, LA_3 and LA_4).

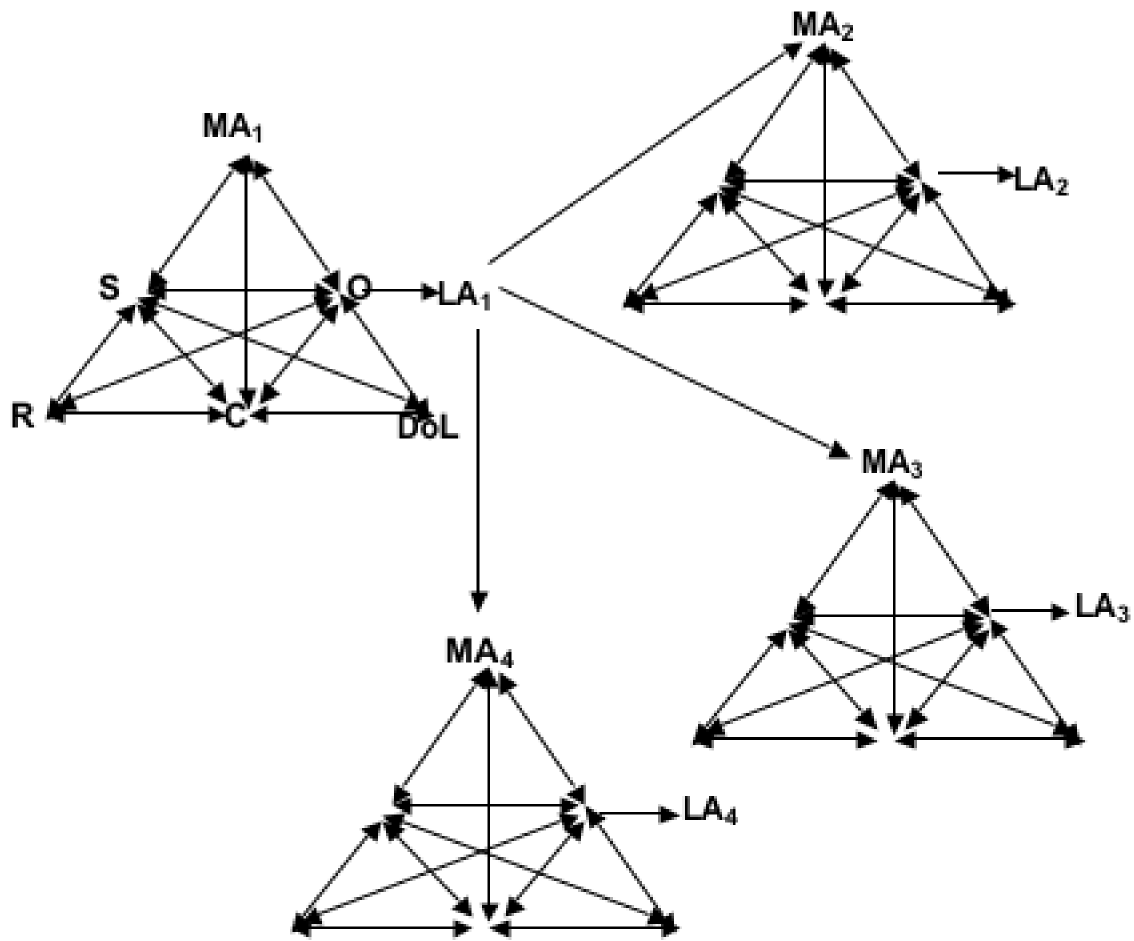

Figure 6: Repurposing a learning activity via a range of Mediating Artefacts

An illustrative example of the application of this approach

This section will show how learning design, pedagogical patterns and Open Educational Resources can be used together in the deconstruction and reconstruction of a resource. There are essentially four different types of Mediating Artefacts: learning design visualisation tools, learning design methods, pedagogical patterns and Web 2.0 sharing and discussion tools (Figure 7).

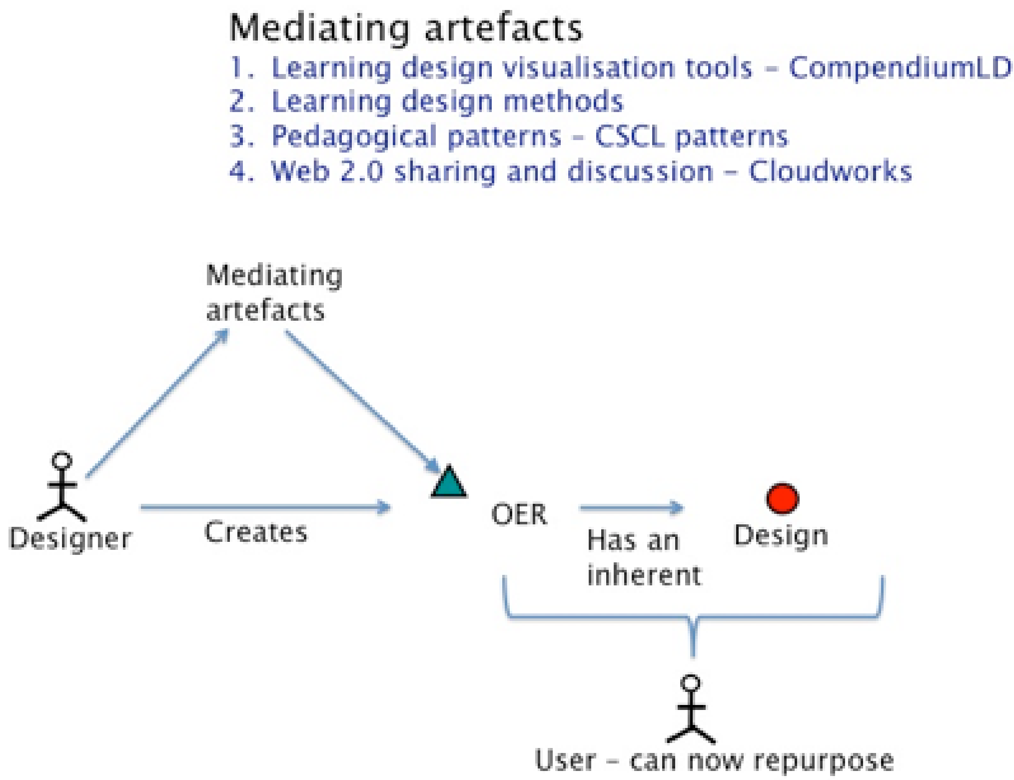

Figure 7: Types of Mediating Artefacts

The following scenario provides an example of how this might work in practice (Figure 8). It describes the creation of an OER and an associated design for the OER and shows how this can be repurposed in three different ways. Tools and resources from OER, learning design and pedagogical patterns research are used to help design the original OER and then to share and repurpose it.

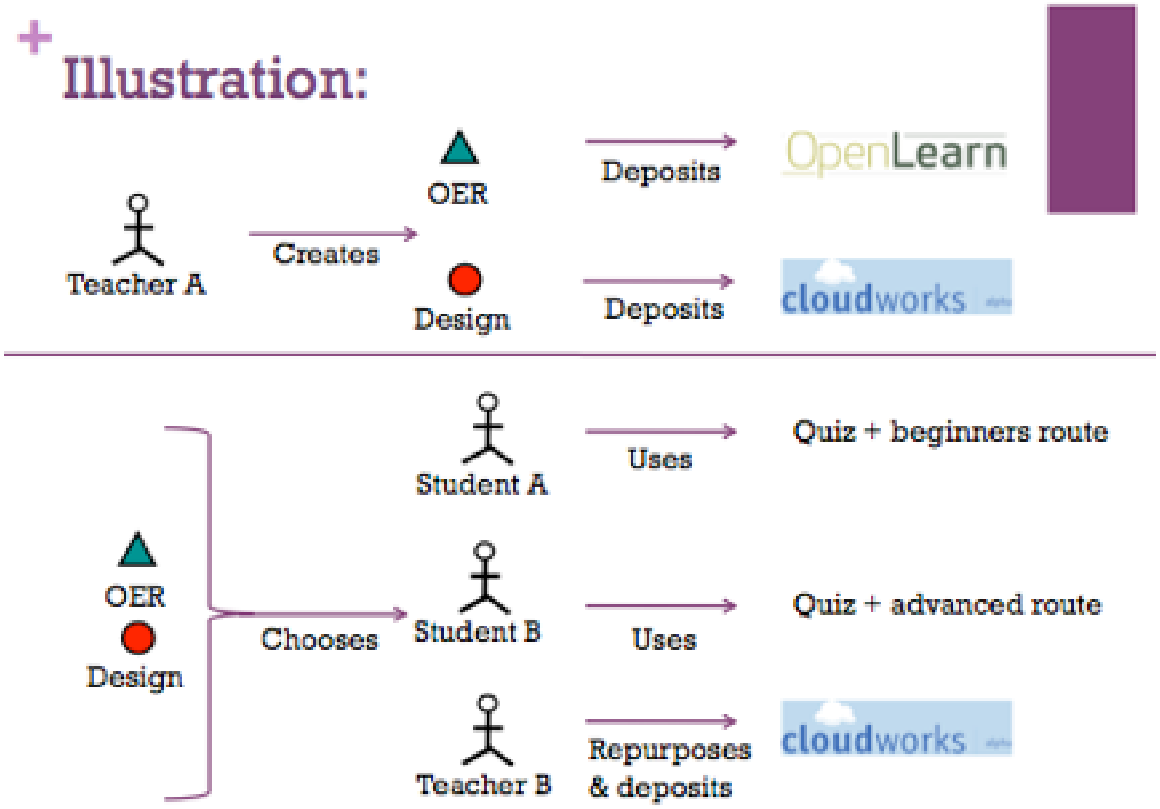

Figure 8: A lifecycle showing the design and reuse of an OER

Teacher A: The design phase

The scenario begins with Teacher A. The context is that Teacher A is putting together their beginners' level Spanish material for the OU course, Portales, L194. They make the material available as an OER online in the Openlearn repository.[18] They use the CompendiumLD tool for visualisation to articulate different ways in which they think the materials can be used. Chapter 9 discusses CompendiumLD in more detail. Figure 9 shows part of the visual design, including the branching sequence to enable a beginner and more advanced route through the learning materials. In particular they are interested in showing how the materials can be used as both a revision exercise for an individual learner and at a more advanced level for a group of learners working collaboratively. Whilst developing their design in CompendiumLD, teacher A had access to ideas and tips and hints from the Cloudworks[19] social networking site for learning and teaching, as well as from a range of OER and Pedagogical Pattern repositories. Chapter 15 discusses Cloudworks in more detail. These help them to refine their design thinking, to get ideas about how to structure activities in the sequences and suggestions of tools that be used for example for supporting a diagnostic e-assessment test or to enable students to communicate synchronously.

[18] http://openlearn.open.ac.uk/course/view.php?id=2439
[19] http://cloudworks.ac.uk

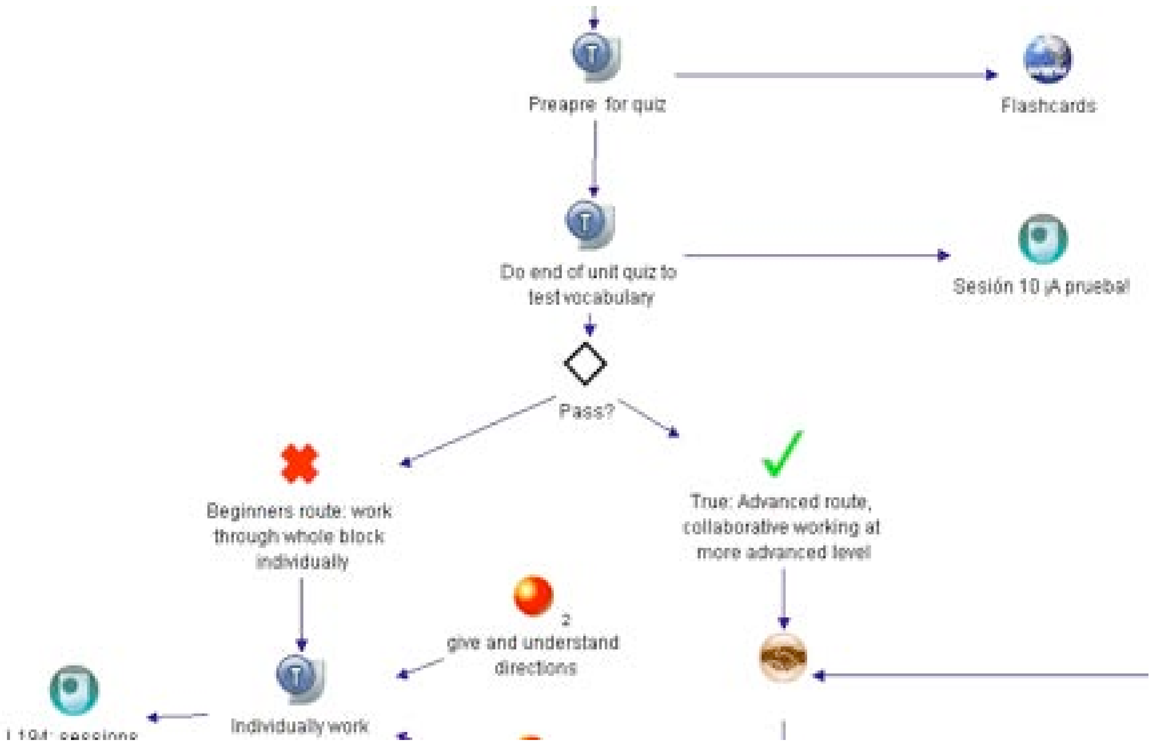

Figure 9: Part of the design sequence created using CompendiumLD

Learner A: Use Scenario 1 – beginners' route

Learner A is studying Spanish. They are a few weeks into an beginner level Spanish course. The topic they is currently working on is 'describing places', they are looking for freely available tools or resources that might help; they are also interested in finding study buddies to work with, who are at a similar level.

1. They explore the OpenLearn site.
2. They find the set of OERs for a beginners' Spanish course – L194 – Portales[20] from the Open University, UK, developed by Teacher A.
3. They find, alongside these resources, the visual design – which provides an example of how these resources might be used. The design consists of the following aspects:
   a) A diagnostic e-assessment test to assess their level of understanding of the topics covered in the course.
   b) Two potential pathways: i) a beginners' route where the learner works individually through the L194 OER material, ii) an advanced route where the learner is assigned to a study group to work collaboratively around one aspect of the L194 OER material, Activity 2.1. In this advanced route, the existing activity (categorise three pictures of buildings as Latin American or Spanish) is replaced with one where the learner has to describe and compare the buildings, working collaboratively with other students and interrogating an expert for information. The activity exploits the jigsaw pedagogical pattern (Hernández-Leo et al., 2006)

[20] http://openlearn.open.ac.uk/course/view.php?id=2439

and also uses a free video conferencing tool to enable the study group to speak with a Spanish cultural expert.

4. They take the diagnostic tests and the advice is that they should take the beginners' route and complete the L194 OER material.

Learner B: Use Scenario 2 – advanced route

Learner B is a student a few weeks into an intermediate level Spanish course. They work through a similar set of activities to Learner A, but in this case after taking the diagnostic test the advice is that they take the advanced route and to focus on the adapted activity 2.1 as a collaborative exercise with other students.

Teacher B: Use Scenario 3 – repurposes

Teacher B is an Associate Lecturer teaching on the intermediate level Spanish course at the Open University, En Rumbo – L140, preparing for a face-to-face tutorial with their students. The topic is describing places. They find the design described above and adapt it to produce two new variants of the design. 1. A classroom-based activity, where the students describe the pictures using the Think-Pair-Share pedagogical pattern (Hernández-Leo et al., 2006). 2. A similar exercise in terms of comparing three buildings, but the students are asked to describe buildings from their town and then talk online with an expert (a student in Spain), who describes their home town. The activity is set as a precursor to the first assignment exercise for the course.

Figure 10 provides a conceptual overview and generalisation of this scenario – showing how an initial design can query existing resources such as Cloudworks, pedagogical pattern repositories and OER repositories, such as Openlearn, use these to help create and populate an OER, along with an associated design, which can then be deposited back into sites such as Cloudworks and OpenLearn for reuse.

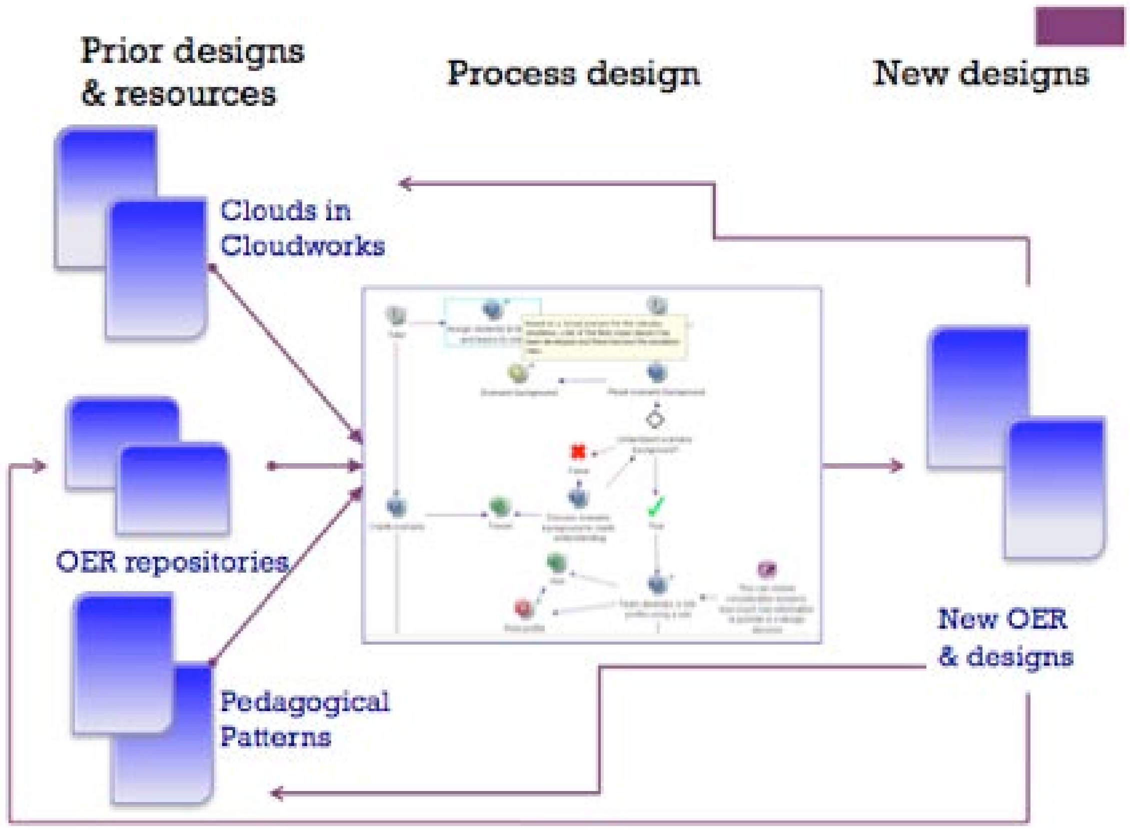

Figure 10: The OER design cycle

In order to test our approach, a number of workshops were held between May and June 2009. Evaluation of these indicated that while determining the pattern of an OER by considering the end product is difficult, the adoption of these collaborative patterns is relatively simple and leads to new views on how OER content can be used. Typically this extends the likely effort of the user and increases the potential for learning from the content without rewriting the core material. This chapter has shown how design presentations, along with a a small number of collaborative patterns, can be used to guide rethinking how an OER works and help repurpose the OER to incorporate more collaboration and adaptability. Further aspects of evaluation of these workshops and analyse of the results is reported elsewhere (Conole et al., 2010; Dimitriadiset al., 2009).

Conclusion

As discussed at the start of this book, the mismatch between the potential of technologies and actual use in practice is one of the most important key challenges facing modern education. Focusing on improving design practices is likely to be one of the most effective ways of bridging this gap.

This chapter has described how the concept of Mediating Artefacts, derived from CHAT, can be applied to a learning design context. It has shown how this theoretical framework can be used to understand the different ways in which learning activities can be represented and the ways in which Mediating Artefacts can be used to support the design process. The chapter argues that articulating the nature of different Mediating Artefacts helps clarify the ways in which each represents different aspects of learning activities. The chapter has described the range of Mediating Artefacts that are commonly used by practitioners, highlighting their different uses. The difficulty of accurately capturing and rarefying practice in this way has been discussed. Overall the chapter has attempted to demonstrate the complexity behind the deceptively simple questions: How can practitioners capture and represent learning activities? How can we provide scaffolding to support the design process? It offers a theoretical framework for addresses these questions using the concept of Mediating Artefacts as the conduit for both abstracting practice from existing learning activities and constructing new learning activities.

Chapter 6 - Affordances

Introduction

This chapter will define the term affordance, starting from its original use in an ecological context, through to its use in Human Computer Interactions (HCI). It will then consider how the term can be used to describe the characteristics of technologies, along with illustrative examples. Although the term is contested,[1] I will argue that it is valuable in that it describes the ways in which the inherent characteristics of different technologies can be instantiated in different contexts, and through the different preferences of individuals and how they interact with technologies. The chapter will describe how the term affordances can be used to help develop a better understanding of the characteristics of different technologies and inform design decisions.

Definitions of the term

Gibson (1977, 1979) defined the term affordances, in an ecological context, in relation to visual perception. He argued that affordances in an environment always lead to some course of action. Affordances are perceived by an individual and are culturally based. Gaver (1991) argues that the actual perception of affordances will be in part determined by the observer's culture, social setting,

[1] See later discussions referencing Boyle and Cook, Gaver, Norman and McGrenere and Ho in this chapter

experience and intentions. For example a button has an affordance of pushing, a knob is for turning and handles are for pushing. Gibson (1977) defined affordances as:

> All "action possibilities" latent in the environment, objectively measurable and independent of the individual's ability to recognize them, but always in relation to the actor and therefore dependent on their capabilities (Gibson, 1977, pg. 67-82).

For example, a tall tree has the affordance of food for a giraffe because it has a long neck, but not for a sheep, or a set of stairs has an affordance of climbing for a walking adult, but not for a crawling infant. Therefore affordances are always in relation to individuals and their capabilities; this includes the individual's past experience, values, beliefs, skills and perceptions. Therefore a button may not have the affordance of pushing if an individual has no cultural context or understanding of the notion of buttons or related objects and what they are for. Gibson also argued that:

The affordances of the environment are what it offers the animal, what it provides or furnishes, either for good or ill (Gibson, 1979, p. 127).

He goes on to argue that it implies a complementarity between the animal and the environment. Salomon describes Gibson's concept of affordances as follows:

'Affordance' refers to the perceived and actual properties of a thing, primarily those functional properties that determine just how the thing could possibly be used. (Salomon, 1993, p. 51).

Therefore affordances are properties of the world that are compatible with and relevant for people's actions (Gaver, 1991). Weiser and Seely Brown (1995) offer the following definition:

An affordance is a relationship between an object in the world and the intentions, perceptions, and capabilities of a person. The side of a door that only pushes out affords this action by offering a flat pushplate. The idea of affordance, powerful as it is, tends to describe the surface of a design. For us the term 'affordance' does not reach far enough into the periphery where a design must be attuned to but not attended to.

McGrenere and Ho identify three properties of affordances (McGrenere and Ho, 2000):
1. An affordance exists relative to the action capabilities of a particular actor.
2. The existence of an affordance is independent of the actor's ability to perceive it.
3. An affordance does not change as the needs and goals of the actor change.

The term was adapted by Norman (1988a, 1988b) for use in an HCI context. His interest was in how the affordances of everyday objects could either enhance or restrict their accessibility. He was interested in using the concept to support the better design of objects to accomplish particular functions. Norman (1988a) said:

When used in this sense, the term affordance refers to the perceived and actual properties of the thing, primarily those fundamental properties that determine just how the thing could possibly be used. A chair affords ("is for") support, and, therefore, affords sitting.

Norman was interested in design and in particular with making affordances salient so that users could easily perceive them. McGrenere and Ho (2000) distinguish between the utility of an object (i.e. the actions it affords for the user), from the usability of the object (i.e. the perceptual information that signals its affordances). Norman considers both perceived and actual properties and implies that a perceived property may or may not be an actual property, but regardless, it is an affordance. Thus, he deviates from Gibson in that perception by an individual may be involved in characterising the existence of the affordance.

Gaver (1991) identifies three types of affordances: perceptible, hidden and false. Perceptible affordances are those where there is perceptual information for the affordance. Hidden affordances are those where there is no information for the affordance (for example a hidden door in a panel). Finally, false affordances are those which can result in a false action.

For Gibson, affordances are binary, they either exist or they don't. In contrast, McGrenere and Ho (2000) consider affordances in terms of two dimensions, i) the ease with which an affordance can be undertaken and ii) the clarity of the information that describes the existing affordance; each being a continuum. They state that the goal of design is to first maximise the necessary affordances and then maximum each of these dimensions (Figure 1).

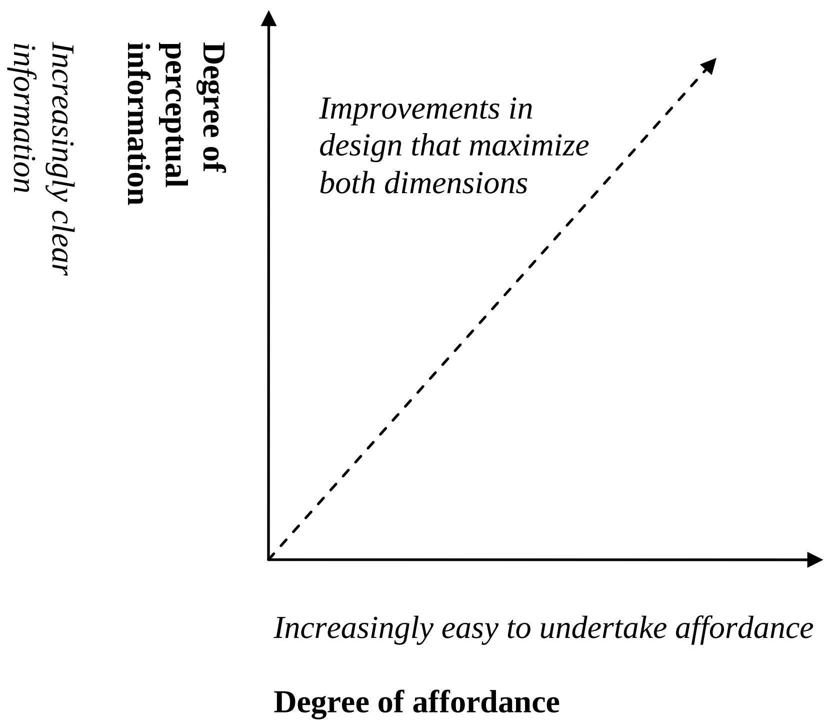

Figure 1: McGrenere and Ho's digram representing the affordance and the information that specifies the affordance as a continuum

McGrenere and Ho's article (McGrenere and Ho, 2000) goes some way towards articulating the different uses of the term by Gibson and Norman. Table 1 summarises the main differences they identified. Boyle and Cook (2004) responding to Conole and Dyke's (2004a) use of the term affordances in a technological context, argue that although the term affordances is potentially rich, it is also contested. Drawing on McGrenere and Ho (2000), they argue that there is considerable ambiguity and confusion in the use of the term. Conole and Dyke (2004b) provide a justification for their use of the term and whilst I agree there is ambiguity, I would argue that the use of affordances as a means of describing the relationship between technologies and users and in particular resultant actions is useful.

Gibson’s affordances	**Norman’s affordances**
Action possibilities in the environment in relation to the action capabilities of an actor	Perceived properties that may not actually exist
Independent of the actor’s experience, knowledge, culture or ability to perceive	Suggestions or clues as to how to use the properties
Existence is binary - an affordance exists or it does not exist	Can be dependent on the experience, knowledge or culture of the actor
	Can make an action difficult or easy

Table 1: McGrenere and Ho’s distinction between Gibson’s and Norman’s use of the term affordances

Drawing on this work, Soegaard (2010) argues that clarifying:

> The distinction between Gibson’s and Norman’s sense of affordances allows us to distinguish between the utility/usefulness and the usability of an object. We both design for usefulness by creating affordances (the possibilities for action in the design) that match the goals of the user (the relativity of the affordance vis-à-vis the user) and we improve the usability by designing the information that specifies the affordances (perceptual information as shadows on buttons to afford clickability etc.).

The next section will consider the types of affordances of technologies and provide examples of how they can be used as a means of guiding the design of a learning intervention.

ICT affordances

Edelson et al., (1999) cite Blumenfeld et al. (1991), who identified six contributions that technology can make to the learning process: i) enhancing interest and motivation, ii) providing access to information, iii) allowing active manipulable representations, iv) structuring the process with tactical and strategic support, v) diagnosing and correcting errors, and vi) managing complexity and aiding production. Technologies provide a mechanism for storing and manipulating large quantities of information, presenting information in a variety of ways, allowing users to interact with materials, and enabling learners to communicate with others to develop their understanding.

Specifically, in relation to Information and Communities Technologies (ICT), Conole and Dyke (2004a) propose the following types of ICT affordances: accessibility, speed of change, diversity, communication and collaboration, reflection, multi-model and non-linear, risk, fragility and uncertainty, immediacy, monopolisation and surveillance. They argue that the taxonomy has a number of uses. Firstly, that establishing a clearer understanding of the affordances should help to inform practitioners in their use of technologies to achieve particular goals. Secondly, that it can also help to identify potential limitations and inappropriate uses of the technologies. Thirdly, by making the inherent affordances of technologies explicit, the taxonomy can act as a discussion point for critique and further refinement. Fourthly, it can be used as a checklist to help practitioners understand the advantages and disadvantages of different technologies. Fifthly, it can be used as a mechanism for staff development and improving practice – for example, by providing a checklist of potential benefits and drawbacks of different technologies which can be used to inform choice and the ways that practitioners might choose to use them. Similarly, Gaver (1991) argues that affordances can be used as a way of focussing on the strengths and weaknesses of technologies with respect to the possibilities they offer the people that might use them.

Conole and Dyke (2004a) were interested in exploring the relationship between the infrastructure of information and communication technologies and people's use of those technologies. In particular, what uses do technologies invite and facilitate, and in which ways can they be used to promote particular types of learning? They were interested in exploring the creative and innovative ways in which people respond to technologies.

Whilst Conole and Dyke's classification is useful in terms of describing ICT and how they can be used, on reflection I now feel that not all of them are affordances in the Gibsonian sense. More recently I have identified a set of positive affordances, specifically in relation to the use of technologies in the design of learning interventions, as well as a list of constraints. Positive affordances include: collaboration, reflection, interaction, dialogue, creativity, organisation, inquiry and authenticity. Constraints include: time consuming (in terms of development), time consuming (in terms of support), difficult to use, costly to produce, assessment issues, lack of interactivity, and difficult to navigate. I will now go on to describe each of positive affordances in turn and give examples of technologies that support them, and will then briefly discuss the pragmatic constraints that need to be addressed.

Identification of the positive affordances of technologies and any associated constraints, can then be used as a means of making informed design decisions in terms of using a particular technology in a specific learning context. For example, to promote student reflection, the affordances checklist can be used in terms of considering the extent to which different tools might promote this. So for example a wiki in this context has the following positive affordance: reflection (to an extent), however arguably a blog has a stronger affordance of reflection and is also better in terms of organisation and dialogue (as if the blog is public others are able to comment on posts). In terms of constraints a wiki is arguably somewhat difficult to use, for some learners anyway. Therefore the checklist might result in the teacher deciding to use a blog, rather than a wiki in this context.

At part of the OULDI work, we have developed an activity based around affordances, which we have used in a number of our learning design workshops.[2] Participants are given the list of positive affordances and constraints and asked to map these to a number of tools for use in a particular learning context. Participants found focusing on the affordances of the different tools a useful way of thinking about their advantages and disadvantages. It helped them focus on the actual use of a tool in a particular context rather than the tool *per se*. They reported that it helped guide their decision making choices in terms of comparing the characteristics of different tools.

The co-evolution of tools and users

Tools and users are not static. Of course technologies are continually developed and upgraded, but more importantly users adapt and change their behaviour and the nature of the way in which they interact with tools over time, as they: i) become more proficient and confident at using the tools, ii) begin to appropriate and personalise use, and iii) see new ways in which the tool can replace

[2] http://cloudworks.ac.uk/cloud/view/4042

previous patterns of behaviour. This section will argue that users evolve their practice as they continue to embed their use of tools. Think for example of the way tools like Microsoft Word and email have become more and more ingrained in everyday practice since their original introduction. This shift is both at an individual and an organisational level. For example, using the Internet to find information is now ubiquitous across education, memos have been replaced by email communication and secretaries no longer laboriously type up hand written letters (Conole, White, and Oliver, 2007).

Pea and Wallis (cited in Borgeman et al., 2008, pg. 11) argue that there is a co-evolution of tools and users over time; interactions and patterns of user behaviour are not static. This co-evolution depends on both the inherent affordances of the tools and the characteristics of the users (i.e. their skills base, personal preferences and beliefs, and the context and culture within which they are interacting with the technologies). While this has always been the case, arguably the pace of change/co-evolution has increased dramatically in recent years, particularly around the use of Web 2.0 tools. There has been a shift from a static-content Web to one that is more interactive; peer critiquing, user-generated content, sharing, personalisation, adaptation, and remixing, are the kinds of user behaviours that characterise these new tools.

Pea and Wallis classify technologies into five phases: early communication mechanisms, symbolic representations such as language and mathematical notation, the first wave of technological media (radio, television, telephone, etc.), the emergence of networked and Internet-based technologies and finally, they argue, we are now in a fifth phases which they term ‘cyberinfrastructure’, which refers to the distributed, global nature of today’s technologies, such as grid and cloud computing. Hence it is evident that there is a co-evolution of tools and users and that this co-evolution depends on both the inherent ‘affordances’ of the tools and the characteristics of the users (i.e. their skills base, personal preferences and beliefs and the context within which they are interacting with the technologies) (Figure 2).

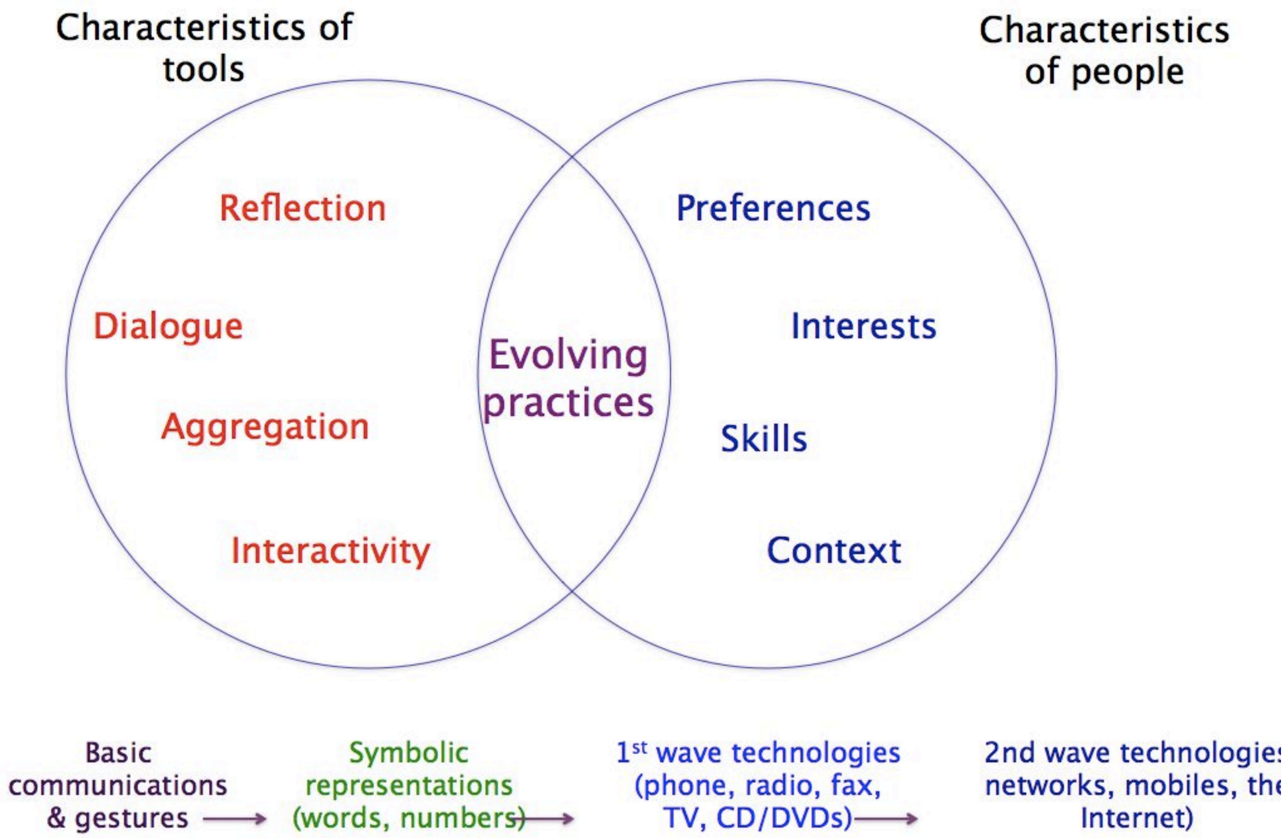

Figure 2: The relationship between the affordances of technologies and user characteristics

I will now discuss each of the positive affordances listed earlier in more detail.

Collaboration

Collaborative learning is an important aspect of socially situated learning. Inherent is the notion that learning with and through others is an important and valuable form of learning, particularly in today's educational context, where the focus is on knowledge co-construction rather than information recall. New technologies have opened up the possibility of new forms of dialogue and communication. ICT offers the potential to develop new forms of online communities and new means of communicating and sharing information, from signing up to specialised mailing lists through to involvement in specialised discussion forums and chat rooms.

It is important to distinguish between collaboration and cooperation. Jones et al. (2007) consider the two terms as follows. They cite Topping's definition of cooperation as:

> CO- means together in company, jointly, in common, equally, mutually, reciprocally, while - OPERATE means to work, act, influence, effect, accomplish, cause or carry out(Topping, 1992, p. 151).

In terms of collaboration, they reference Kaye, who defined collaboration as:

> Etymologically, to collaborate (co-labore) means work together, which implies a concept of shared goals, and an explicit attempt to 'add value' - to create something new or different through the collaboration as opposed to simply exchanging information or passing instructions. (Kaye, 1992, p. 2)

Dillenbourg (1999) defined collaborative learning as:

> A *situation* in which *two or more* people *learn* or attempt to learn something *together*. (Dillenbourg 1999, p2; emphasis in original).

Jones et al. (2007) see co-operation as been applied more to a division of labour in which individuals achieve their aims by mutual assistance, whereas collaboration implies a stronger commitment to joint aims, as well as mutual assistance.

Collaboration can be promoted through a range of technologies. For example action learning sets[3] can be set up in a discussion forum, where the students work together on a shared project, using the space to share and discuss ideas. Similarly a wiki can be used as a space to support joint project writing. Social bookmarking sites can be used by a cohort as a means of aggregating a shared set of resources.

Reflection

The importance of reflection can be traced back to the work of Dewey (1916; 1933; 1938; 1949). Dyke et al. (2007) reference Dewey's definition of the term. They argue that Dewey contrasts reflective thought with reliance on instruction and the mere transmission of received wisdoms and defines reflection as:

> [A] better way of thinking that … is called reflective thinking: the kind of thinking that consists of turning a subject over in the mind and giving it serious and consecutive thought. Dewey 1938, p. 113).

Dewey also stated that:

> The function of reflective thought is therefore to transform a situation in which there is experienced obscurity, doubt, conflict, disturbance of some sort, into a situation that is clear, coherent, settled, harmonious (Dewey 1933, p. 195).

Asynchronous communication tools, such as forums, have long been considered to offer opportunities to support student reflection (Garrison, 2002: Lyons, 2010; Mason and Kaye, 1989). Forums can be used in a semi-structured and moderated way or more openly as a space for students to share and discuss ideas. They provide a space for students to reflect and critique, where students can engage in discussion over a longer timeframe than is possible with face-to-face discussions. They can be used to augment face-to-face discussion providing a space for students to reflect on in-classroom debates.

Blogs can be used very effectively as a means of promoting reflection (Kerawalla et al., 2008; Yang, 2009). For example students can be asked to keep a reflective blog, which can be shared with the teacher, other students or more broadly. This is particularly useful in professional courses, where it is important for students to gain a clearer understanding of the theory they are learning and its relationship to professional practice. For example when trainee teachers are on placement in schools keeping a reflective blog of their experience and its relation to educational theory can be very effective. Finally, e-portfolio can also be a good way of promoting reflection, as well as providing a mechanism for learners to aggregate and evidence their learning (Buzzetto-More, 2010; Jafari and Kaufman, 2006; Stefani et al., 2007).[4]

---

[4] See also the JISC 'Effective practice with e-portfolios' guide, http://www.jisc.ac.uk/publications/programmerelated/2008/effectivepracticeeportfolios.aspx

Interaction
One of the often cited benefits of new technologies is the way in which it can promote a range of interactions. The nature of interaction in online spaces is discussed in more detail in Chapter 14, where I separate out community (between learners and peers), from interaction (with technologies). I am using the term interaction here in terms of the interaction between users and technologies. It is concerned with the extent to which the user can manipulate their environment. Wagner defines interaction as follows:

> Interactions occur when these objects and events mutually influence one another. An instructional interaction is an event that takes place between a learner and the learner's environment. Its purpose is to respond to the learner in a way intended to change his or her behavior toward an educational goal. Instructional interactions have two purposes: to change learners and to move them toward achieving their goals (Wagner, 1994).

Siemens (2005) argues that interaction is essential for effective learning. Similarly Dyke et al. (2007) see interaction as one of the key aspects of effective learning, along with learning through thinking and reflection, from experience and activity, and through conversation.

Dyke et al. (2007) suggest that the non-linearity of the Web leads to the potential for different routes through tools and resources and different forms of learning. They argue that ICT enables the learner to move beyond linear pathways of learning, characteristic of, but not exclusive to, behaviourist approaches, and to adopt more individualised strategies and pathways.

Another aspect of the interaction affordance of ICT is the potential for multi-modal and non-linear approaches to learning. Multimedia tools provide a way of giving learners not just access to materials, but also a means of interacting with the materials. Examples include virtual simulations, where learners can change variables and see the effect on a model of say an ecological system. E-assessment tools can allow students to test out their understanding of a topic through a range of different types of online assessment questions types. The system can then provide either instant feedback or forward the results for a teacher to provide feedback later. Clearly publishing tools such as blogs and wikis provide the user with the ability to produce user-generated content. In addition there are now a range of tools that can allow users to mix and match different functionality, such as mash up tools. Gaming environments and virtual worlds allow the user to interact in digitally authentic, specialised spaces. User actions in games for example will result in particular paths through the gaming material to be taken. In virtual worlds it is also possible for users to acquire or even build new objects and personalities.

Dialogue
Learning through discussion with others is an important and well recognised aspect of learning, going back to Vygotsky's work (Vygotsky, 1962; 1978).

New technologies have opened up the possibility of new forms of dialogue and communication. ICT offers the potential to develop new forms of online communities and new means of communicating and sharing information; from signing up to particular mailing lists through to involvement in specialised discussion forums and chat rooms. New technologies provide a plethora of ways in which learners can communicate with their peers, their teachers and others beyond the course cohort. Tools such as Twitter provide learners potentially with access to an international community of others with shared interests, providing the opportunity for just-in-time learning. As a learner of Spanish I have used Twitter extensively in this respect. If I posted a tweet on something I didn't understand (for example the use of the verbs ser and estar in a particular context) I would invariably get a near instant response from a number of people, providing me with different explanations of which term should be used and when.

Similarly peer critiquing via blogs provides a mechanism for others to comment on thoughts and ideas. Indeed this is a technique I have used in the process of writing this book, in that I have posted draft chapters on which others have then provided comments.

Synchronous communication tools, such as chat tools, and audio and video conferencing provide a different forum for debate and discussion and can be used in a variety of ways, to come to an agreed consensus on something, to discuss issues, to brainstorm ideas or as a backchannel to support events. In Chapter 15, I describe the way in which the conferencing tool, Elluminate, was used in conjunction with the social networking site, Cloudworks, to provide a rich interactive environment for discussion and debate.

Creativity

In a call for a special issue of the journal, EURODL,[5] Sorenson et al. (2010) argue that creativity is a key digital literacy skill that learners need to develop. They cite Runco (1996) who argues that:

> Creative thinking reflects the original interpretation of experience (Runco, 1996). Each of us has the capacity to construct original interpretations, and if it is a useful and original interpretation, it qualifies as "creative." That is how creativity is typically defined, as both useful and original (Barron, 1955; Runco, 1988).

Runco (2008) also argued that creative potential should be a primary concern for educators and that educators need to recognise that creativity is widely distributed, virtually every individual has the mental capacity to construct the personal interpretations that are involved.

The term creativity is derived from the latin term 'creo' meaning to create or make.[6] It is about making something new (either a physical artefact or a concept) that is novel and valuable. It is about the ability to transcend traditional ideas, rules, partners, relationships and create meaningful new ideas, forms, methods and interpretations. It is important because it is an essential skill, needed to deal with today's complex, fast changing society. Furthermore, it is evident that it can be promoted through discourse and collaboration that are mediated through a range of social and participatory media.

Wallas (1926) identified the following five stages of creativity:

- Preparation - identifying the problem.
- Incubation - internalising of the problem.
- Intimation - getting a feeling for a solution.
- Illumination - creativity bursts forth.
- Verification - the idea is consciously verified, elaborated and applied.

Therefore, according the Wallis, the creative process moved through the initial identification and focus on a particular problem, through a moment of enlightenment and finally to validation through sharing with others.

Technologies can be used in a variety of ways to support creativity. They can promote creativity in new and innovation ways. They can enable new forms of discourse, collaboration and cooperation. They can provide users with access to knowledge, that can be repurposed or represented via different forms of representation. New social and participatory media, in particular, enable the aggregation and scaling of information; distributed and collective.

[5] http://olnet.org/sites/default/files/OPEN-CALL-CreativityOER.pdf

[6] http://en.wikipedia.org/wiki/Creativity

Sorenson et al.'s special issue of EURODL is exploring the ways in which creativity can be promoted through the use of OER. In the call for papers they argue:

> In this special issue we are interested in exploring in more depth the nature of *creativity* and how this might be understood and used to better harness the potential of OER. In related work we have explored how alternative theoretical perspectives such as drama might influence our imagination in relation to how we use OER (Sorensen 2010), and how the use of collaborative pedagogical patterns might be used to support use of OER in collaborative learning contexts (Conole et al. 2010).

Other social and participatory media can also be used to promote creativity by representing knowledge in different ways, enabling learners to connect with others globally, and by providing multiple, often serendipitous, routes through information.

Organisation
Being able to organise information is an important skill and an important part of the learning process. Learners need to be able to find and organise relevant information for their learning, so that it can be archived and easily retrieved. Learners need to be able to combine different sources of information to construct new understanding and meaning in relation to a particular topic. Arguably the way information is organised forms a kind of mental schema, which in itself can act as a learning aid.

Asynchronous tools, like discussion forums, can be used by students to access and build up an archive of material relevant to their course. More generally there are now a range of tools that students can use to aggregate resources, such as social booking sites. Referencing tools are useful as a means of organising research papers, and can be used not only to compile references, but also as a means of building up an annotated bibliography. Recommender sites can also be useful in terms of suggested related items of interest to a user, and RSS feeds mean that information can be filtered and pushed to the end user according to their own learning preferences.

Inquiry
Inquiry-based learning has long been recognised as one aspect of constructivism. The Personal Inquiry (PI) project (Sharples and Scanlon, 2011) for example developed an inquiry-based learning model (NQuire),[7] which was used as the basis for an online toolkit to promote inquiry-based learning in the development of scientific understanding in school children. Edelson et al. (1999) argue that inquiry-based learning is particularly important in a science context because science is essentially a question-driven, open-ended process and therefore students need to have personal experiences with scientific inquiry to understand this. They go on to suggest that inquiry activities provide a valuable context for learners to acquire, clarify and apply an understanding of science concepts.

Effective use of search engines can be used to foster inquiry-based learning, although it is important to note that learners need to acquire the necessary critical literacy skills in order to evaluate the relevance of the resources they find.

Authenticity
Learning-by-doing is another effective way to learn. Authentic learning is important in a rapidly changing world where the volume of information is ever expanding and where learners are likely to have multiple careers. Therefore the development of expert thinking and complex communication are key skills for learners to develop. Lombardi (2007) argues that:

[7] http://www.nquire.org.uk/

The Internet and a variety of emerging communication, visualization, and simulation technologies now make it possible to offer students authentic learning experiences ranging from experimentation to real-world problem solving.

She goes on to state that learners often express a preference for learning by doing, and that they are motivated by real-life problems. Technologies provide a variety of mechanism for offering students authentic learning experiences based on experimentation and action. Furthermore providing students with access to online research communities, enables them to develop a deeper sense of the disciplinary culture.

Authentic learning focuses on real-world problems and can be promoted through role-play, problem-based learning, case studies and participation in virtual communities. Technologies can provide learners with access to real research data and researchers. Visualisation tools and haptic technologies can provide students with authentic experiences, closely mimicking real world contexts. One example is the HapTEL project,[8] which has developed a virtual learning system that includes haptic and synthetic devices for use by trainee dentists.

Technologies can also enable students to cohabit persistent simulations or metaverses, allowing them to role-play, look at multiple perspectives to the same set of issues and adapt to a dynamically changing situation. Conole and Dyke (2004a) argue that:

Information technologies provide a means by which people can be exposed to experiences very different to their own and extend their experience beyond their own communities. Experience of the ‘other’ through technology raises issues around authenticity and power in the “virtual reality” that can be accessed. For example, there may be disjuncture between the mediated ‘reported’ experience and the reality of lived experience. It raises questions about how one distinguishes between what is real and what is rendered real via the technology.

Constraints

In addition to considering how different technologies can be used to support different forms of pedagogy through the affordances outlined above, there are also a number of constraints, which the designer needs to consider. Firstly, a particular technology may be time consuming in terms of the development of it to support a particular learning intervention. Secondly, it may be time consuming in terms of the amount of support that the teacher needs to give to the learners in using the technology. For example, forums can require an significant amount of moderating. Thirdly, the technology may be difficult to use. For example, for some wikis are difficult to get used to. Virtual worlds, like SecondLife, take time to adjust to and learners may need considerable support when they first use these tools. Fourthly, tools may be costly to produce, for example rich multimedia resources not only take time, but resources to be developed. However, with the advent of the many free tools that are now available for producing content, arguably this is becoming less of an issue. Fifthly, there may be assessment issues with use of particular tools, for example what is the most appropriate way to assess group work using a wiki? Sixthly, tools may lack interactivity, for example static Web pages, leading to potential student disengagement. Finally, use of online social and participatory media can result in learner confusion and can be difficult to navigate, hence clearly signposted learning pathways might be needed.

Conclusion

This chapter has defined the notion of affordances and discussed it in relation to the affordances of different technologies. It has argued that the term is valuable in that it describes the way in which there is a complex and dynamic co-evolving relationship between technologies and users. By

[8] http://www.haptel.kcl.ac.uk/

considering first the positive affordances and then the constraints of different technologies in a particular learning context, practitioners can make more informed design decisions.

Chapter 7 – Design languages and learning design

Introduction

This chapter provides a definition for the term 'design language' and provides examples of how it is used in a number of professional domains. It summarises the research on design languages and considers how this relates to the notion of a learning design language. It provides a useful contextual background to the discussions in later chapters on the design visual representations and associated visualisation tools, such as the CompendiumLD tool[1] developed as part of the OULDI work. The chapter draws in particular on Botturi and Stubbs (2008), who provide an authoritative account of design language research.

Design is a key feature of many professions, the chapter considers design practices in three disciplines: music, architecture and chemistry and describes how design approaches have been developed in each of these. I then summarise some of the key characteristics of

[1] http://compendiumld.open.ac.uk/

design practice and explore the implications of these in terms of the application of design principles to an educational context.

The challenges of designing for learning

Falconer and Littlejohn (2008, p. 20) argue that there are three challenges facing teachers: i) the increasing size and diversity of the student body, ii) the increasing requirement for quality assurance, and iii) the rapid pace of technological change. Conole (2004) has argued that there is a gap between the promise and reality of the use of technology in education and that there is little evidence that education has changed fundamentally as a result of the use of technologies. Much use of technology appears to simply replicate bad classroom practice resulting in simple Web page turning (Oliver, 2000). Similarly Masterman (2008a, p.210) argues that the lack of uptake of technologies is due to a number of factors: lack of awareness of the possibilities, technophobia, lack of time to explore the use of technologies, aversion to the risks inherent in experimentation and fear of being supplanted by the computer. Agostinho et al. (2008, p. 381) suggest that the uptake of the use of high-quality ICT-based learning designs in higher education has been slow. Factors include: low levels of dissemination of ICT-based learning projects, lack of ICT-based learning examples to model, lack of time, support and training. Sawyer (2006, p. 8) argues that the impact of the significant investment in computers in schools has been disappointing. There are few studies that show that computer use is correlated with improved student performance. Similarly, Koedinger and Corbett (2008, p. 61) write that as new technologies have emerged many hoped that they would have a radically transformative effect on education, but in reality the impact has been much less than expected.

A key issue is that teachers do not know how to design, mainly adopting an implicit approach based around prior experiences and practices. Falconer and Littlejohn (2008) explored practitioners’ design practices through a series of workshops. As a result they identified the following challenges with representing models of practice:

- Ownership of representations - different representations are effective for different communities, and there are a number of different purposes a representation needs to fulfil.
- There are issues around the purpose of representations – in terms of being generic or a detailed sequence used for orchestration or offering inspiration to teachers in terms of implementing them and hence changing practice.
- Designs are both a product and a process, both aspects are important
- The degree of granularity of the design, they found the most common level of granularity is around a lesson plan for one – three hours of learning.

Practitioners’ approaches to design

The extensive range of data collected in the OULDI described earlier in this book provides a rich body of empirical evidence to inform our thinking and the development of appropriate tools for design. In summary we have conducted a series of interviews (Clark and Cross, 2010), workshops and focus groups with practitioners to elicit their approach to design and any associated challenges. A series of key questions were asked, including: the process of design - how do practitioners go about designing learning interventions?

The representations of design - what representations (textual and visual) do they use? Where do they get help and support? How do they share and discuss their designs with others? How do they evaluate the effectiveness of the designs? In addition, the workshops and focus groups enabled us to explore in more depth different aspects of the design process.

Participants were given the opportunity to use a range of representations to create, share and discuss design ideas. The workshops included detailed feedback and evaluation and the artefacts produced were shared on the social networking site, Cloudworks,[2] which is discussed in Chapter 15. Data was also analysed for 43 case studies of the use of the Moodle VLE course management tool. The case studies were derived from a series of interviews with OU course leaders[3] (Wilson, 2007). The focus was on the pedagogies used to achieve specific learning outcomes and the use of tools (blogs, wikis, e-assessment, etc.) to support learning activities. Interviews were semi-structured around four core themes: contextual data (level, subject, etc.), details about the learning activity being described and the sub-tasks involved, pedagogical approaches adopted, and barriers and enablers to the creation of the activity (both technical and organisational). Each interview lasted about an hour and was recorded and transcribed. Following this, the text was edited in a standard template form and a diagrammatic representation of the learning activity drawn. The content was checked for accuracy with the interviewees.

This section provides a summary of some of the key findings from the empirical data, a more detailed discussion of some of the findings from the interviews with teachers/designers in provided elsewhere (Cross et al., 2008; Clarke and Cross, 2010).

The empirical data provided a rich picture of the way in which teachers design. It was evident from the data that there was no one perfect tool for design and that individuals had different preferences of how they went about the design process - some sketching ideas out and linking them, others working systematically from learning outcomes, whilst others used the subject content as a baseline for development. Some used a combination of approaches at different stages of the design. The interviews and case studies provided valuable insights into the design process that cluster into five overarching themes: the process of design - how practitioners go about designing learning activities, support and guidance - where they get ideas and support from, barriers to innovation - what barriers or problems they encounter, representing designs - the ways in which they articulate and visualise designs, and evaluation mechanisms - the ways in which they assess the effectiveness of the designs they create (Figure 1).

[2] http://cloudworks.ac.uk

[3] OU courses as designed by teams of academics, associated lecturers then support the learning and mark assignments.

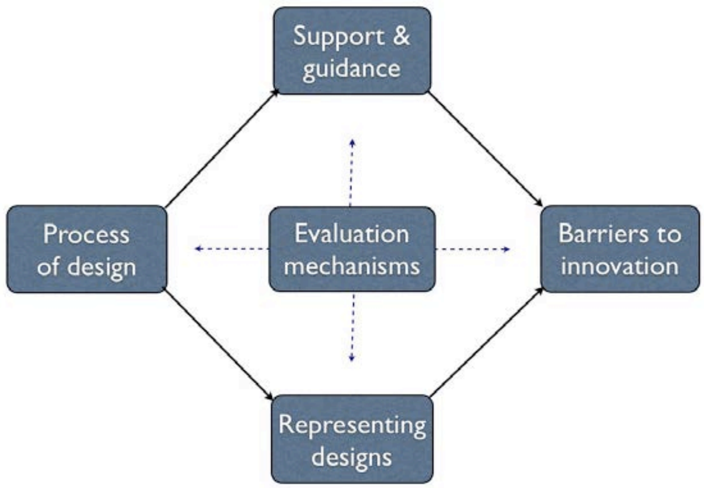

Figure 1: The five overarching themes on design approaches and methods

The most prominent finding from the interviews was that design is a messy, creative and interactive process, and that even when working in teams there is a large element of individuality in the design process. Teachers design at different levels of granularity and focus on different aspects of design over the design lifecycle. Both the interviews and the workshops gave us a clearer understanding of the design strategies that teachers adopt. Foci for design include: looking at learning outcomes and mapping these to assessment strategies, integrating the use of external resources with locally authored materials, designing activities to test understanding, integrating a range of tools and approaches, addressing different learner preferences and levels of competence, and mapping to externally prescribed professional requirements. The following quote, from one of the practitioners, is illustrative of this:

> It's not in one direction. Not sure if I always start with aims, sometimes I do! Broad aims, then thinking about the mix, go to the palette and look at existing resources, what will the budget allow us to do (chairs hat on), what additional resources do we need, which would be most effective to teach certain things. For example, we need this software to help teach linguistic analysis. We might want some video analysis, so think about how to bring in video sequences, what videoing needs to be done. Then start writing. It's chicken and egg. Sometimes start with study guide and then think about activities, and then think I need this bit of video. But you don't always have luxury of working in this direction or budget to do filming so start looking for other sequences and build activities around those. [Interview 160607]

The following quote gives an example of how a teacher iteratively develops their concept of the course over a period of time and how they kept an evolving record of relevant resources and materials for the course:

> I was building a sense of what the new course might be ... we must remember to do x, or a url of relevance. [Interview 160607]

It was also evident that design for a new course is very different to design when redeveloping a course based on interpretation of student feedback and evaluation. The interviews revealed that there was no simple route to teachers accessing support and guidance on the design process. Little use appeared to be made of online resources and networks - most adopted a serendipitous approach, relying on peer practitioners and close colleagues for ideas. One interviewee from the case studies conducted by Wilson (2007) said:

> This says more about me than it does about the stuff really but I preferred the corridor conversations. It was a way of ... I had invested quite a lot of money in coffee and so there were a whole set of people across the university who I took to coffee and pumped them for what I could really. [Case study interview, 210107]

Those interviewed recognised the value of sharing and reuse, but there was little evidence that they shared their designs with others or adapted and repurposed designs created by others. Different forms of representation of learning activities (textual, visual, etc.) all had different advantages and disadvantages and there was evidently a distinction between the process of producing a design and design as an artefact. When shown visual presentations of learning activities for example, many of those interviewed found it difficult to interpret them, to apply/adapt them to their own context. However, on further probing they could see a genuine benefit in using visual tools as a means of mapping their own practice, as is evident in the following quote from one of the interviews:

> [On the value of a visual representation] It always needs to be brought to life, to have some form of enactment... Would I want to see what someone else has done, yes I suppose so. [Interview, 141107]

The conflict between the process of the dynamic creation of an activity and the associated sense of ownership the designer has in the process, contrasts with design as a product, a static artefact. For example one interviewee struggled to see the benefit of a visual representation of someone else's design, even though it was an activity in her subject area. She continued later in the interview to argue for the need for a mediation role to help interpret designs and as she says 'make them come alive':

> [One being shown a visual representation of a learning activity] It's such a different context and level. This is language teaching rather than linguistic teaching. And there isn't the contextual information, even with you having just explained a little, which helped, without you there I'd be looking at this and thinking... I think there'd be too much work to look in to this plus the recontextualisation. I wouldn't spend the time to be honest.
>
> I really think you need someone who goes to the course team, although not necessarily staying with them. And sits down, not right at the start but a little way in, and asks what are you teaching and what resources are you going to use alone or in combination and that person would go away do some work and come back - have some insight into bringing together their knowledge of the technologies available and which would best fit your intention and provide you with a map - that's when a map would work, they'd be bringing it alive. [Interview, 141107]

The interactive and holistic nature of the design process came out strongly across the data:

> One of the difficulties is mapping the whole process I have tried to approach course design using a holistic approach. [Interview, 121107]

Teachers differed in the extent to which they worked visually or textually; some used software, others sketched or wrote out ideas, one teacher had a scrapbook which he used as he was developing his design ideas:

> It's in words, not diagrams a dumping ground for thoughts - [to] capture thoughts. [Interview, 121107]

Others used visualisation as a means of mapping different elements of the design process:

> List of words clustered into blocks, arrows...can you have clusters link to TMAs[4] [Assignments]. [Interview, 141107]

> Start from assessment strategies and learning outcomes and get an alignment. [Interview, 151007]

> I tend to sit and doodle a map - will draw the logic and flow of the course on paper and then go to Compendium. Then the problem is sharing it. [Interview, 291107]

The interviews also highlighted a number of contradictions about the process of design, forms of representation for design and the nature/type of support, which teachers wanted. Firstly, there was a tension between design as process and design as artefact; both were considered important. Secondly, there is the difficulty of capturing what is inherently an implicit process. Thirdly, teachers wanted subject-specific case studies and examples. Fourthly, there are a variety of influences on the different forms of representation and individuals interpretations of them. Fifthly, there is the desire for specific, just-in-time help and support. Finally, there is the issue of how to map the evolving, dynamic and changing nature of design.

Similarly, the Learning Management System (LMS) case studies (Wilson, 2007), highlighted a range of overarching themes:

- Designers/teachers relied extensively on their prior experience and the local context for development.
- There was uncertainty associated with the constantly changing functionality offered by available technologies.
- The willingness, access and ability to facilitate the transfer of good practice varied considerably.
- Existing online learning design resources (case studies, theoretical frameworks, toolkits) were used very little.
- The design process is messy, creative and iterative.
- Existing institutional systems did not adequately reflect new ways of working and effective use of new approaches and technologies.

[4] Tutor Marked Assignments

- The need to take account of the changing nature of the student and academic roles and associated skills set.
- The importance of motivating individuals (both learners and teachers) in driving forward innovative practice.
- The increase in the amount of online activities and materials used in courses has lead to the necessity for more frequent re-designs of courses.
- Issues emerged about the balance of resources and activities associated with the OU's Supported Open Learning (SOL)[5] two-stage process of production and presentation.

The interviews also gave us a better understanding of the nature of the design lifecycle. Figure 2 outlines the six main aspects of the design lifecycle. The cycle begins with the designer's vision and focus for the learning intervention. The second stage is the gathering of relevant resources and tools. The third is assembling these into a sequence. The fourth is running the learning intervention. The fifth is evaluating its effectiveness. The final stage is adaption in light of evaluation feedback, which may in turn lead to changes in the original vision. These six stages can be mapped from course conception, through delivery and finally evaluation. The cycle can operate at a number of levels: a learning activity (typically of the order of a few hours of learning), a block level (usually a semester's worth of work) and a course level (which might be a masters or degree level course programme).

[5] This is discussed in more detail in Chapter 11

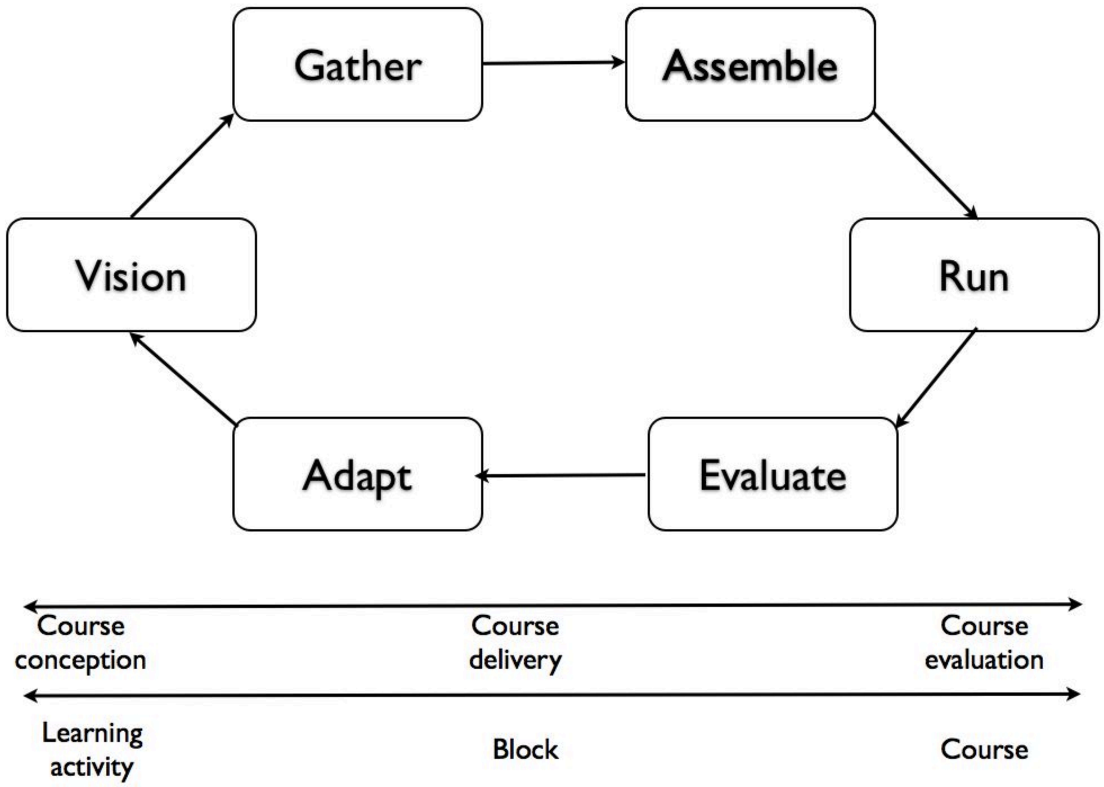

Figure 2: The five overarching themes on design approaches and methods

Repurposing an Open Education Resource

In related work, as discussed in Chapter 5, we explored teachers conceptions of design in terms of how they might repurpose stand-alone Open Educational Resources (OER) to support their used in collaborative learning activities (Conole et al., 2010). A series of workshops were run, in which participants explored existing OER and used a set of collaborative pedagogical patterns (Hernández-Leo et al., 2006) to redesign the OER for use in a collaborative learning context. The workshops were video recorded and the discussions transcribed. The findings from this work were similar to the findings from the interviews and case studies described earlier. Analysis of the data revealed a number of themes that are discussed here. Part of our approach is predicated on the notion that OER have inherent designs and that if we can make those designs more explicit this will aid repurposing. A number of themes emerged with respect to this, which are discussed in this section. In the following sections participants are represented as P1, P2, etc. while the workshop facilitators are indicated as F1, F2, etc.

It was evident that there were a number of ways in which textual representations could emphasise different aspects of the design – some were descriptive in nature, others were more metaphorical and others more operational – for example a bullet list articulating steps in a learning sequence. A common approach adopted by the participants was to have a temporal sequence. Another strategy was to focus mainly on the content and associated resources. Participants started from different perspectives; some began by considering the learning objectives, whilst others started with the content or activities:

> **P2:** My resource is a design by itself. So, it is the design of an activity, it is the representation of that, a few bullet points and then a graphical representation. …. So the resource basically represents arrows pointing into a sequence of the activities.

It was interesting to see the extent to which each of the representations was easily sharable with others. More often than not a dialogic engagement was necessary to help make sense of the design and to clarify misunderstandings. The exercise and subsequent discussion enabled us to tease out both the main facets of design and participants' different perspectives and approaches. In addition to articulating objectives, content and tasks, some of the participants evidenced a subtler level of design – associated with the inherent principles of the design:

> **P3**: My resource is task-driven, so that is the principle and also it integrates many pedagogies into the content, so, and also it is question based.

In terms of principles we explored whether or not they had articulated a principle around individuality/collaboration. A range of characteristics was identified as being associated with the design – the objectives, generic characteristics, sequence of tasks undertaken, and whether it had an individual or collaborative focus. Participants recognised that it was important to clarify what information was essential to communicate so that the activity could be subsequently taken up and adapted by others:

> **F1:** Just try to think again of what elements you wrote down and what elements you used when you tried to explain it to your neighbour and try to think whether they were mainly based on objectives, mainly based on the characteristics of the activities, of a temporal sequence or …

One of the participants suggested that it would be valuable to have multiple views of the same design each view representing a different aspect:

> **P7:** So probably having different layers of visualization of the same structure could help filter the relevant information if you are looking at the learning objectives, or if you are looking at interactions, something like that, so, another thing that we were thinking about it probably what is missing is a legend of the different items, because we understood that there is a mixing of two layers, one is devoted to the designer, for example, all the questions in blue are annotations for the designers while for example it is very clear that the sequence for students is talking to the student verbally, it is talking to him, so probably having the legends saying ok, question mark annotation for the designer and the red bits are feedbacks we had from one evaluation and then filtering visually this information according to the task you are following.

This participant also argued that visualisation potentially has additional power, particularly if a semantic dimension is included:

> **P7:** A semantic of visualizations, really we understood that some of the connection are more related to cognitive activities of the design where as others are tactical activities of the use (missing comment) and cause and some other connection are like database

connections with the resources and what they are looking, so probably having different semantic of the connections and representations.

Another aspect of importance, that participants mentioned, was identifying the quality and provenance of the resource; i.e. designs need to do more than display the sequence of activities, users need some indication of how effective and fit for purpose it is. There are two ways in which this can be achieved. Firstly, in the design representation itself, however the more detail that is included in the design the more complex it is. Secondly, an alternative is to have a wrap-around dialogue about the resource and its design, in a social networking site, such as the Cloudworks site[6] which is discussed in more detail in Chapter 15. The data revealed that deconstruction and subsequent reconstruction of OER is complex, indeed it is possible to identify four layers that need to be considered to make most effective repurposing of an OER. Conole et al. (2010) identified the following four aspects of this:

1. Visual representation of the design. How can the implicit OER design be made more explicit and hence shareable?
2. Opinion of goodness. How appropriate is the OER for use in different educational contexts?
3. Transferability through pedagogical patterns. How can generic patterns be applied to specific contexts?
4. Level of discussion, critique and contextualisation. How might social networking sites, like Cloudworks, act as a supporting structure to foster debate between those using the same OER?

In conclusion describing design was seen as a difficult and unfamiliar task. It is evident that there are multiple solutions to any one design problem. There are also many options for what can be included and it is hard to interpret designs in a consistent way. Finally, any one design representation is only able to capture partial details.

Design languages

It is worth beginning by comparing general language use with design language. Language is what people use for communicating information and ideas; design language is what designers use to communicate design plans, and intentions to each other. Cole et al. (1997) argue that “the languages used to a great extent shapes what can and cannot be thought and said” (cited in Gibbons and Brewer, 2005, p. 113).

Design languages can be used to both generate designs and as a mechanism for interpreting and discussing them. They are used in a range of professions, where there is a focus on developing a specific artefact of some kind. Examples include: architecture, music composition, writing, choreography, mathematics and computer programming. With reference to the design of software systems, Winograd (1996) argues that design is not a static noun, but refers to the activity of design. He identifies a number of important aspects: design as a conscious process, design as dialogue with materials, design as a

[6] http://cloudworks.ac.uk

creative process, design as a communicative process and design as social activity. He describes design languages as “visual and functional languages of communication with the people who use an artefact. A design language is like a natural language, both in its communicative function and in its structure as an evolving system of elements and relationships among those elements” (Winograd, 1996, p. 64).

Botturi and Stubbs (2008) demonstrate that there is a plethora of languages available to choose from; ranging from sketch-oriented languages that facilitate the creation and representation of the grand view of a design to more formal languages that enable detailed representations of specification and/or implementation details of a design. Botturi et al. (2006, pg. 1), citing Gibbson and Brewer, define a design language as “a set of concepts that support structuring a design task and conceiving solutions”. They go on to define a design language as a mental tool that can be expressed and hence communicated through a notation system (i.e. a set of signs and icons that allow representing a design problem or solution so that it is perceivable by our senses).

Design theory refers to identifying methods (or models, techniques, strategies and heuristics) and when to use them. Reiguluth and Carr-Chellman (2009, p. 7) argue that design theory is different from descriptive theory, in that it is goal oriented and normative. It identifies good methods for accomplishing goals, whereas descriptive theory describes cause-effect relationships. Arguably teachers need to develop both – design expertise through application of a design-based approach to the creation of learning interventions and descriptive expertise in terms of interpreting and understanding the learning that takes place. The Open Learning Design methodology described in this book aims to facilitate the development of both approaches.

Goodyear and Retalis (2010) describe the role of language generally in terms of supporting abstract thought and the ability to deal with complex conceptual change. They argue that it involves the creation and manipulation of symbolic representations of the world.

Gibbons et al. (2008) argue that design languages are an important aspect of instructional design. They define a design language as a “set of abstractions used to give structure, properties, and texture to solutions of design problems”. Hohanson et al. (2008, p. 19) suggest that a design language is “what designers use to communicate designs, plans and intentions to each other and to the producers of their artifacts”, citing Gibbons and Brewer (2005, p. 13). Rose (2001) argues that understanding visual representations is a learned skill. As I will discuss elsewhere in this book, there are a range of new digital literacies that teachers need to acquire in order to design effective learning interventions that make effective use of new technologies (Jenkins et al., 2006; Jenkins, 2009).

Visual languages serve several purposes: i) to communicate a message through a visual or functional language, ii) to provide a synthetic idea, image or metaphor of complex ideas and iii) to create a grammar or produce meaning for its use. Gibbons et al. (2008) argue that design languages: i) encourage disciplined design practice, ii) give organisation to the growth of design fields, iii) helps give historical context to evolving design fields and iv) connect practices of a design field to theoretical concepts.

Botturi et al. (2006) argue that educational modelling languages have emerged as conceptual tools to help designers deal with the increasing complexity of designing for learning making effective use of new technologies and pedagogies. They argue that they enable the development of reflective practice and potentially enhance a more thorough understanding and reuse of e-learning. Derntl et al. (2008, 2010) suggest that a shared design language is one mechanism for dealing with design complexity and the requirements of communication in interdisciplinary design teams. They argue that designing for learning needs both 'beauty' and 'precision'; and they show how different design languages can be used to present these. They state that "we are in no way suggesting that beauty and precision are in opposition to one another, nor even that they are mutually exclusive concerns. We make the distinction merely to further stress the competing demands on instructional designers for maintaining a grand view of the learning experience while also addressing the myriad details of an effective end product".

Stubbs and Gibbons (2008, p. 35) suggests that visual representations serve two purposes in design: i) they can be used during design as part of the design process to represent some aspect of instruction before it is produced or represented (this may be in the form of storyboards or flow charts) and ii) they can be part of the content that is being produced. They also argue that design drawing can aid the designer by reducing cognitive load during the design process and because a design sketched is an external representation, it can augment memory and support informational processing. They also suggest that another view of drawing is similar to Vygotsky's description of the relationship of language to thought (Vygotsky, 1978). Substituting drawing for words, Vygotsky said: "Thought is not merely expressed in (drawings), it comes into existence through them". Languages in general provide advantages that are particularly useful in design. Firstly, they allow thought to be communicated so that good ideas do not get lost. Secondly, they provide a focus of attention that permits higher-power processing and anchoring of thought. Thirdly, they provide the ability to question and judge the value of the thought – to construct thoughts about thought. Jackendoff (1996) suggests that there are two stages to the design process: sketches to try ideas out and, as the design progresses, the drawings become more formal, and more governed by rules and conventions.

McKim categorises abstract graphic languages into seven types: Venn diagrams, organisation charts, flow charts, link-node diagrams, bar charts and graphs, schematic diagrams and pattern languages, (McKim, 1980), whereas Laseau (1986) categorises them into four main types: bubble diagrams, area diagrams, matrices and networks.

Massironi (2002) has produced a taxonomy of graphic productions, which categorises design drawings by their form and purpose. He distinguishes between representational (physical reality) and non-representational (abstract concepts) drawings. Botturi (2008, p. 112) identifies two types of languages: i) finalist communicative languages, which serve the purpose of representing a complete instructional design for communicating it to others for implementation, reuse or archive and ii) representative, which help designers think about the instruction they are designing and support its creation. The ability to express an idea allows people to better analyse and conceptualise it and to make better design decisions.

Boling and Smith (2008) describe the range of Mediating Artefacts that are used to support design both as process and product. The way in which we are using the concept of Mediating Artefacts in the design process is described elsewhere (Conole, 2008) and was discussed in more detail in Chapter 5. Boling and Smith highlight the importance of sketching and consider the interplay between the two modes of mental representation required for sketching – propositional (largely symbolic) and analogue (quasi-pictorial, spatially depictive). They reference Goldschmidt (1991), who argues that there is an oscillation between propositional thinking and descriptive thinking during the process of design.

Botturi et al. (2006) described a number of commonly used design languages. A selection of these is provided here. The intention is not to be comprehensive, but to give an illustration of the different kinds of design languages that have been developed and to describe how they are used for different purposes and with different kinds of users; the examples described range from computer runnable formal languages through to more ‘fuzzy’ and less formal languages that are aimed at practitioners.

Gibbons and Brewer (2005, p. 121) argue that once a notational system is established it can become: i) a tool for remembering designs, ii) a structured problem-solving workspace in which designs can take form and be shared, and iii) a kind of laboratory tool for sharpening and multiplying abstract design language categories. Indeed it is evident that there is a complex evolution of design languages and associated notations and that this evolution is closely tied to the nature of the subject domain and what is of particular importance to foreground and emphasise. So for music it is ensuring the accurate representations of the sounds in time, for architecture it is seeing the ways in which the different components connect and how they look overall and in chemistry it is about foregrounding the associated chemical properties and patterns of behaviour of the atoms and molecules.

Gibbons and Brewer (2005, p. 115) list a set of dimensions of design languages. The first is complexity, namely that design are merely partial representation of much more complex, and multifaceted ideas in our minds. The second is precision, there is a tension between the natural, fuzzy nature of real practice and tightly defined specification. This tension is very evident in an educational context, in particular in the specification of formal technical learning designs that can be translated into machine-readable code as opposed to fuzzy, practice-based designs. The third is formality and standardisation, which refers to the importance of ensuring that terms used mean the same to all users. The fourth is the tension between personally created designs and those that are shared with others. Designs only become public or sharable through negotiation and interaction with others. Designs should never be seen as static artefacts and are always dynamic and co-constructed in context. The fifth is the tension between implicit, individual designs to those that are completely explicit with clearly defined terms and rules. Again this is a crucial issue in an educational context, where traditional teaching practice has been implicit and designs fuzzy. Shifting to more explicit and sharable designs requires a change of mindset and practice. Related to this are issues around standardisation verses non-standardisation. In terms of these points, there is a tension with designs in terms of how much they focus on precise presentation, specification and how much on the more aesthetic, visionary aspects of the design. Derntl et al. (2008) consider this in an instructional design context, arguing that:

> On the one hand, solutions should be creative, effective and flexible; on the other hand, developers and instructors need precise guidance and details on what to do during development and implementation. Communication of and about designs is supported by design languages, some of which are conceptual and textual, and others more formal and visual.

They present a case study where both a creative solution (‘beauty’) and clear-cut details (‘precision’) are sought. Finally there are issues around computability. Some languages are formalised and precise and hence can be converted into machine runnable code. Gibbons and Brewer (2005, p. 118) go on to argue that designs can be shared in two ways: i) by a description that relies on natural language or ii) through a specialised notation system that uses figures, drawings, models or other standard symbolic representations to express the elements and relationship of the design.

Designs have a number of components. Firstly, the context in which the design is created and used; i.e. a design carries with it a socio-cultural element, i.e. the background and context, both of the individuals involved and the educational setting. Secondly, the inherent beliefs of the designer; i.e. a design carries with it intentions, aspirations and beliefs. In a learning context this is the designer’s beliefs about what should be learnt and how it should be achieved. Donald et al. (2009) see this inherent belief basis of teaching practice as a vital tool for unlocking and shifting practice. They have developed a learning design system, HEART (HEaring And Realising Teaching-voice), which aims to support teachers learning design practice by eliciting and depicting the pedagogical beliefs underpinning a learning design or a resource. In an educational context our implicit designs are based on a mix of theoretical concepts, prior examples, personal ideals and idiosyncratic opinions. Finally, designs should encourage reflection and should support iterative redesign and reuse.

Design notation in music, architecture and chemistry

I now want to turn to some examples of how design languages are used in other professions. I will consider three examples: the development of musical notation, architectural designs and design in chemistry.

Musical notation

Daziel (2009) compares the development of a learning design notation to the emergence of a notation for music. Musical notation captures abstract musical designs in the form of graphical, textual and symbolic representations. It is precise enough that a piece of music written by a composer from 300 or 400 hundred years ago can be accurately replayed. Early musical notations can be traced back to 2 000 BC, but the standard notation used today is a relatively recent phenomenon, before its development, music had to be sung or played from memory. This severely limited the extent and reach of music, as well as resulting in a loss of fidelity of the original music as they were transferred from person to person memorising them. Musical notation went through a range of forms before settling on the notations we use today (Figure 1). The notation includes a complex set of instructions about not just the notes to be played and their sequence, but the timing, intonation and even some of the emotion embodied in the music.

Figure 1: Music notation[7]

Architectural notation

Architectural notation helps articulate and share an architect's origin vision behind the development of a building and make it explicit and sharable with others involved in the design and development of the building. For example, Figure 2 shows some modern architecture in Valencia. The building manages to convey both functionality with emotion and an element of organic form. The creation of this will have involved a complex range of design representations; from the initial vision/intent of the architect through to actual creation of the building. Buildings are complex and three-dimensional. Design decisions have to cover a range of factors; such as the layout of the building, the relationship between the different components, the types of materials, the nature of the site where the building will be located, etc.. Different designs are therefore needed to relate certain elements of the design to each other, while ignoring others, and these allow the designer to see their creation from different perspectives. Three-dimensional visual representations are often annotated with text and supplemented by tables of data. In recent years design representations in architecture have being computerised with the emergence of sophisticated Computer Assisted Design (CAD) tools. Arguably use of these CAD tools has influenced the practice of design, in addition to facilitating more effective sharing of designs.

Figure 2: An example of modern architecture in Valencia

Chemical notation

Chemists use a number of design representations, from chemical symbols for individual atoms, through various visual representations for displaying molecules and chemical equations for the design of chemical synthesis and for explanation of particular chemical properties (Figure 3). As with music and architecture, the design representations that have been developed closely mapped to the discipline itself and the key focus of interest. Chemistry is fundamentally concerned with the properties and chemical behaviours of individual atoms and how these can combine in different ways to create molecules with different properties. Two-dimensional representations are common (for example chemical equations), but three-dimensional representations are also useful and particularly valuable when looking at large molecules with complex typologies. As in architecture, a number of computer-based tools have now been developed to enable drawing and manipulation of molecules. These can in some instances be based on real data, such as the atomic coordinates of individual atoms and so are also powerful modelling tools as well.

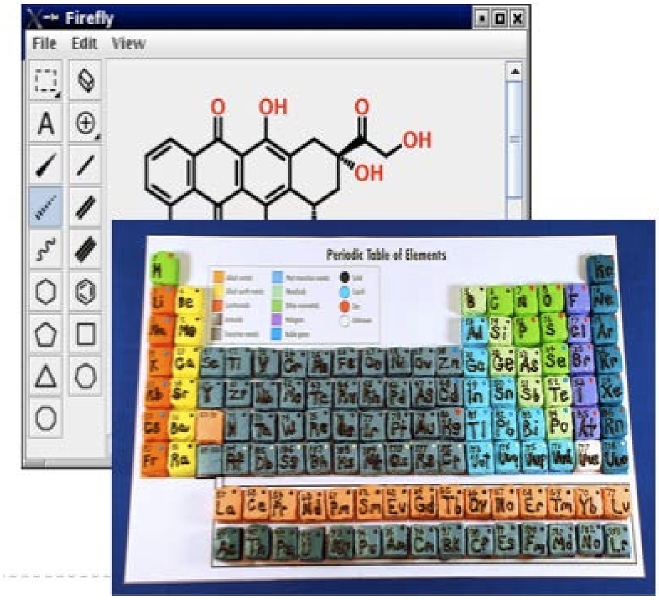

Figure 3: Chemistry notations[8]

Learning design

This section describes the emergence of learning design as a research field. This is an important and vibrant research field and there have been a number of edited collections in recent years (Beetham and Sharpe, 2007; Lockyer et al., 2008). One of the main drivers for the emergence of learning design as a research field is arguably that teachers are now presented with many choices in how they can design and deliver their courses (Agostinho, 2008). They are confused by the plethora of technologies and different pedagogical approaches they can adopt. Furthermore, teachers often struggle with implementing theory into practice (Fang, 1996). Kelly et al. argue that “modern educational interventions must respond to new scientific knowledge emerging from technology-infused, Internet-intensive, highly social, networked science” (Kelly, et al. 2008, p. 3).

Learning design as an approach aligns with a number of related research work, in particular research on pedagogical patterns (Goodyear and Retalis, 2010) and Open Educational Resources (Iiyoshi and Kumar, 2008). The Iiyoshi and Kumar book provides an overview of the open content and knowledge movement, of which Open Education Resources research is one aspect. I will provide an overview of these related fields and will attempt to show how these areas are related to, but also distinct from learning design. I intend to make a more explicit connection between the area of learning design, pedagogical patterns and Open Educational Resources. See Conole et al. (2010) for more on this. I discussed aspects of this work in more detail in Chapter 5. Goodyear and Retalis (2010) provide a useful edited collection of current research in the field of pedagogical patterns. This includes a chapter by Conole and Jones (2010), which begins to align the

[8] Sources: http://www.flickr.com/photos/8272941@N07/498827420/ and http://www.flickr.com/photos/chemheritage/3984920162/

learning design and pedagogical patterns research, through the description of a learning activity as both a visual learning design representation and as a pedagogical pattern. As discussed in Chapter 2, the work also aligns with related research in instructional design and learning sciences (Reigeluth and Carr-Chellman, 2009; Sawyer, 2006; Spector, al., et 2008).

Design is arguably *the* most important aspect of learning and teaching. However, design tends to be based on prior experience, practitioners make limited use of different pedagogical approaches; effective design enables teachers to make informed use of technologies and incorporation of innovative pedagogies approaches, which can meet the challenges of today's rapidly changing educational context. However, design is complex and teachers need support and guidance to effectively incorporate new technologies, to think differently, and to change their practice. This book outlines a means of achieving this, along with practical tools and methods. All of the tools and methods described are freely available.

Defining learning design

Learning design as a research field has emerged in the last ten years or so, primarily driven to date by researchers in Europe and Australia. Before describing the methodology we have developed at the Open University, I will provide a brief overview of the development of the field and some of the key features and milestones. The learning design research work has developed in response to a perceived gap between the potential of technologies in terms of their use to support learning and their actual use in practice (Bennett et al., 2007; Conole, 2004; Herrington et al., 2005). Much of the learning design research is concerned with mechanisms for articulating and sharing practice, and in particular the ways in which designs can be represented.

Learning design has developed as a means of helping teachers make informed choices in terms of creating pedagogically effective learning interventions that make effective use of new technologies. Learning design representations enable teachers to document, model and share teaching practice. Learning design also encompasses both the process of designing learning experiences, as well as the product, i.e. outcome or artefact of the design process.

A learning design can represent different levels of granularity – from a whole course down to an individual learning activity. In addition, it can be a formal representation, which is computer runnable or simply a semi-formal way of describing the learning intervention.

Goodyear and Yang (2008, p. 167) use the related term educational design, which they define as "the set of practices involved in constructing representations of how to support learning in particular cases or the set of practices involved in constructing representations of how people should be helped to learn specific circumstances". They argue that "educational design takes time, it rarely starts with a clear complete conception of what is desired". The process of iterative clarification of the nature of the problem and its solution involves complex thought. Goodyear (2005) also further elaborates on the definition of educational design as:

The set of practices involved in constructing representations of how to support learning in particular cases.

This distinguishes design from development - the practices of turning these representations into real support for learning (materials, task specifications, tools, etc). It distinguishes design for particular educational applications from the broad consideration of learning in general. It focuses on practice rather than theory, while recognising that practice embodies experiential and theoretical knowledge. Goodyear (2005) identifies three aspects of educational design. The first is the design of good learning tasks. The second is the design and management of the learning environment. The third focuses on the social aspects of learning. Goodyear and Retalis (2010) argue that good design is hard and takes time, it involves the design of good tasks, but also the design of supportive learning environments. Design works indirectly, learners have the ability to adapt, customise and invent. Design works at various levels, from the detailed functionality of a tool right up to institution-wide infrastructure.

Beetham and Sharpe prefer the term ‘designing for learning’, which they define as:

The process by which teachers – and others involved in the support of learning – arrive at a plan or structure or design for a learning situation (Beetham and Sharpe, 2007, p. 7).

Like Goodyear and Yang (2010), they believe that learning can never be wholly designed, only designed for (i.e. planned in advance) with an awareness of the contingent nature of learning as it actually takes place.

Beetham (2007, p. 28) defines a learning activity as:

A specific interaction of learner(s) with other(s) using specific tools and resources, orientated towards specific outcomes. See Figure 4.[9]

Within this context a learning outcome is intended to lead to some identifiable change that is anticipated in the learner. Beetham argues that because a learning activity emerges as the learner engages in a task, the elements identified are in practice highly interdependent and can only fully be defined when the activity is completed. As the figure shows, at the centre is the learning activity that the leaners work through. There are four aspects to achieving this. First, the characteristics of the learners. Second, the intended learning outcomes. Third, the environment and associated tools and resources. Fourth, the nature of the interactions with other learners and teachers.

[9] Derived from Beetham and Sharpe (2007, p. 29)

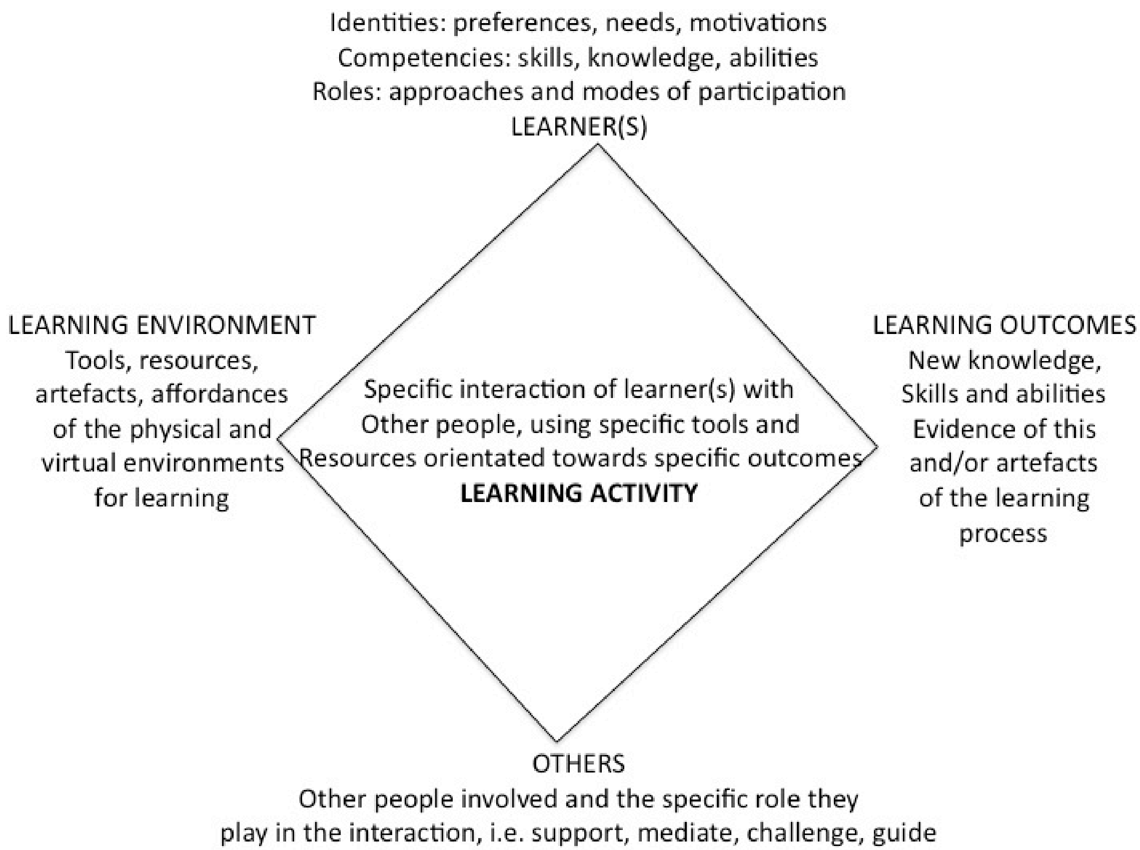

Figure 4: The components involved in a learning activity

Chatteur et al., quoting Neal and Miller (2005), argue that e-learning design is a careful balancing act between pedagogy and technology; often at the expense of pedagogy (Chatteur et al., 2010, p. 183). They go on to argue that designing e-learning is a particularly complex task and quote Rittel and Webber (1973) arguing that design can be described as a 'wicked' problem (Chatteur, et al., 2010, p. 184).

The origins of learning design

The origins of the term learning design can be traced back to work at the OUNL in the Netherlands in terms of the development of a Learning Design (LD) specification, which subsequently translated into the IMS LD specification.[10] From a review of learning theories an Educational Modelling Language (EML) was developed (Koper and Manderveld, 2004) and from this a Learning Design specification was derived (see for example Koper and Oliver, 2004 and Koper and Tattersall, 2005). Focusing very much at the technical level, it was claimed that the LD specification was pedagogically neutral and could be used to describe any learning intervention. The specification was based on a theatrical metaphor, describing the roles of those involved in the intervention (learners, teachers, etc.), the environment in which it occurred, and the tools and resources involved. Inherent in the approach was the assumption that educational practice can be represented in a design description, i.e. that underlying design ideas and principles can be

[10] http://www.imsglobal.org/learningdesign/

captured in an explicit representation. In addition, the design of a course is driven by 'pedagogical models' that capture the teacher's beliefs and is a set of rules that prescribe how leaning can be achieved in a particular context. Koper and Oliver (2004: 98) define Learning Design as:

An application of a pedagogical model for a specific learning objective, target group and a specific context or knowledge domain.

IMS/LD represents a learning design, referred to as a 'unit of learning', which is a sequence of activities described in the form of acts in a play. It is a formal computer language that both documents the final contextualised learning design and executes the learning design to the learner. It describes the roles and activity sequences within an environment of learning objects and services. Properties, conditions and notifications can also be defined to further fine tune and specify the design. It specifies the learning-teaching process. A number of tools have since been created to run IMS LD specifications, but the work has not had a fundamental impact on changing teacher practice, focusing more on the technical description and running of the designs. These include the RELOAD LD editor,[11] the CopperCore editor,[12] Collage,[13] and MOT+.[14] Botturi and Stubbs (2008) provide a more detailed description of these and other related learning design editing tools.

UML (Unified Modelling Language)[15] has also been adapted for use in e-learning contexts. Botturi et al. (2006) describe E2ML, which is based on UML, as a simple design language coupled with a visual notation system consisting of multiple interrelated diagrams. Agostinho (2008) lists three types of E2ML documents: goal definition, action diagram and overview diagram.

Since then others have appropriated the term learning design in a much broader sense, shifting to the notion of 'designing for learning'. Cross and Conole (2008) provide a simple overview of the field; see also Conole and Galley (2011). The focus of the research is both to better understand and represent design processes, along with developing tools and methods to help practitioners create better designs. A number of benefits of adopting a more formal and rigorous approach to design have been identified (Conole, 2009). In terms of the OULDI research work, we define learning design as:

> A methodology for enabling teachers/designers to make more informed decisions in how they go about designing, which is pedagogically informed and makes effective use of appropriate resources and technologies. This includes the design of resources and individual learning activities right up to whole curriculum level design. A key principle is to help make the design process more explicit and shareable. Learning design as an area of research and development includes both gathering empirical evidence to better

> understand the design process as well as the development of a range of resource, tools and activities.

In parallel, work in Australia embraced a broader notion of the term 'learning design', which was located more at the level of practice than technical specification. The AUTC Learning Design project[16] aimed to capture a range of pedagogical models as learning design case studies with the intention that these could then be used by teachers to guide their practice and enable greater sharing and reuse of designs (Agostinho, 2008; Oliver, et al., 2002).

The work was based on a framework for describing learning designs developed by Oliver and Harrington (Oliver, 1999, Oliver and Harrington, 2001). This was based on three critical elements: learning tasks, learning resources and learning support. The intention was that thinking about each of these elements helped to both guide the design process and make it explicit and shareable. The approach was used to represent a range of learning designs across different pedagogical models, such as: role play, problem-based learning, concept-based learning and collaboration. The AUTC LD project produced detailed guidelines on each of the design case studies they captured, representing these visually using an updated version of the design representation developed by Oliver and Harrington, along with detailed descriptions on how the design was produced and how it can be used. A number of studies have been conducted exploring how the AUTC designs are actually used by teachers.

Buzza et al. (2004) focussed on the 'Predict, Observe, Explain' AUTC design[17] with four teachers and two instructional designers. Overall the participants recognised the value of the designs and how they might be used, although the researchers concluded that widespread adoption of the IMS Learning Design specification would not be possible until a controlled vocabulary can be agreed upon for use in cataloguing and searching for learning designs. Agostinho et al. (2009) explored to what extent the AUTC designs were effective learning design descriptions, i.e. how they could provide adequate information that can be easily understood in terms of content and thus potentially reused by a teacher in their particular educational context. Their findings were that there are three important features of an effective learning design description: i) a clear description of the pedagogical design, ii) some form of 'quality' rating, and iii) guidance and advice on how the design could be reused.

In the UK the Joint Information Systems Committee (JISC) funded a series of projects under the 'Design for Learning programme' (see Beetham, 2008 for a review of the programme and the lessons learnt). The term 'design for learning' was used rather than learning design to indicate a broader scope and a more holistic approach, although I would argue that the way in which I define learning design in this book is synonymous with this broader perspective. Design for learning was defined as:

---

[17] http://www.learningdesigns.uow.edu.au/exemplars/info/LD44/index.html

A set of practices carried out by learning professionals… defined as designing, planning and orchestrating learning activities which involve the use of technology, as part of a learning session or programme (Beetham, 2008, p. 3).

The programme included a review of e-learning pedagogical models, which classified learning theories into three main types: associative, constructive and situative (Mayes and DeFreitas, 2005). The Mod4L project[18] explored what different types of design presentations were being used by practitioners and concluded that de-contextualised designs or patterns could not in practice form the basis of a generic design typology, in which a finite number of educationally meaningful intentions could be discerned (Falconer, et al. 2007).

The programme also supported the development of two pedagogical planner tools, Phoebe (Masterman, 2008b) and the London Pedagogical Planner (these are discussed in Chapter 10). The programme divided the design lifecycle into four parts: design, instantiation, realisation and review. The granularity of the designs ranged from the design of learning objects or short learning activities up to broader sessions or whole courses/curricula. Beethem (2008) described some of the key lessons derived from the programme included the following. Firstly, design practices are varied, depending on individuals, subject differences and local cultures. Secondly, design tools are rarely perceived as pedagogically neutral and most are not considered flexible enough to match real practice. Finally, there were mixed views from practitioners on what were the most appropriate ways of representing and sharing designs – some wanted rich, narrative representations, others wanted bite-sized representations that could be easily understood and reused.

A spectrum of learning design languages

Agostinho (2008, p. 14) reviewed commonly used learning design languages categorising them as follows:

1. Pedagogical patterns.
2. Generic learning designs – patterns and generic Learning Design Visualisation Sequences (LDVS).
3. Contextulaised learning design instantiations – LDVS, LDLite and E2ML.
4. Executable runnable versions – IMS LD, LAMS.

Agostinho et al. (2008) argue that the AUTC visual learning design representation can be used to facilitate dissemination and reuse of innovative pedagogical strategies in university teaching. Agostinho (2008) also refer to this as a Learning Design Visual Sequence (LDVS). It is intentionally aimed at teachers as an easy to understand representation. It can be used both to represent and share examples of good designs or help guide a teacher through the creation of a learning design.

Harper and Oliver (2008, p. 228) developed a taxonomy for learning designs arising out of the AUTC Learning Design project[19] which gathered over 50 exemplar learning

[18] http://www.academy.gcal.ac.uk/mod4l/
[19] http://www.learningdesigns.uow.edu.au/

designs. The AUTC designs were categorised into five types of design: collaborative designs, concept/procedure designs, problem-based learning designs, project/case study designs and role-play designs. As discussed earlier, the AUTC design language is much more practitioner orientated, than IMS LD. It is based on work by Oliver and Herrington (2001), who identified three elements associated with a learning design:

1. The tasks or activities learners are required to undertake.
2. The content resources provided to help learners complete the tasks.
3. The support mechanisms provided to assist learners to engage with the tasks and resources.

These three elements are used to describe a learning design, as a temporal sequence, with the tasks or activities being undertaken in the centre and the associated resources and support mechanism for each tasks or activity represented either side. These are represented by three symbols: squares (tasks), triangles (resources) and circles (support). Figure 5 shows an example, from the Mekong eSim role play design.[20] It shows the content or resources the learners interact with on the lefthand side, the tasks or activities that the learners are required to perform in the middle and the support mechanisms provided to assist learners in engaging with the tasks and resources on the righthand side. Harper and Oliver (2008) argue that there has been little work to provide a means to classify and categorise learning designs. The designs were evaluated using an adapted version of the framework developed by Boud and Prosser (2002), based on the following critieria: learner engagement, acknowledgement of the learning context, learner challenge and the provision of practice. They identified the following four types of learning design:

1. Rule focus – based on the application of rules.
2. Incident focus – based on incidents and events.
3. Strategy focus – that require strategic thinking, planning and activity.
4. Role focus – where the learning outcomes are based on learners' performance and personal experiences.

[20] http://www.learningdesigns.uow.edu.au/exemplars/info/LD42/more/03Context.html

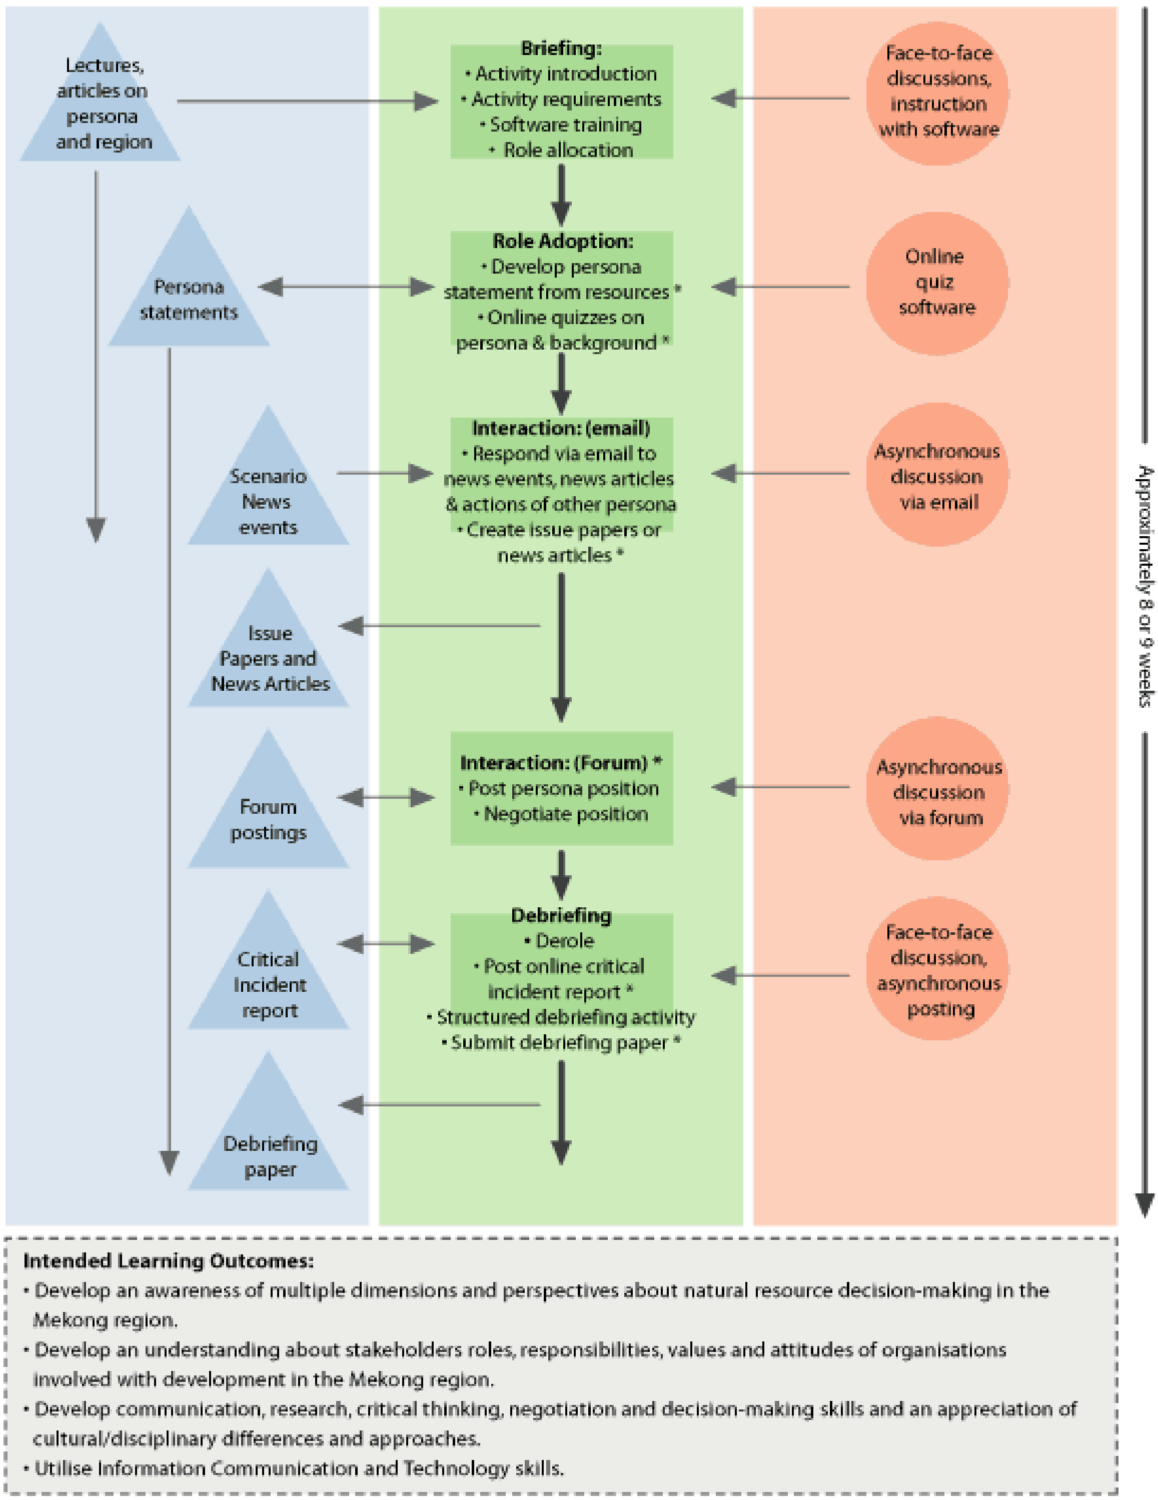

Figure 5: The Mekong eSim learning design - an example of the AUTC learning design visualisation

Another simple representation, also aimed at teachers, is LDLite (Oliver and Littlejohn, 2006), which shares many similarities with lesson plans that K-12 teachers are familiar with. It is based on five aspects of a design: tutor roles, learner roles, content resources, service resources and assessment feedback. It consists of a matrix which has the following as column headings: tutor role, student role, resources (content), resources (services) and assessment feedback. The rows describe each of these in terms of the online and offline elements of the learning intervention.[21]

The MOT+ design language is based on the MISA instructional design method (Paquette, 2004; Paquette et al., 2008). It starts from the premise that building a design is based on two fundamental questions. What knowledge do we want the learners to acquire? How should the activities and resources best be organised to achieve this? It is a graphical representation, which consists of three elements: concepts, procedures and principles.

The Learning Activity Management System (LAMS), like IMS/LD, is a computer runnable design language (Dalziel, 2003; Dalziel, 2007). The main strength of the LAMS tool is that it provides a simple visual representation of the design, based around the tools and activities that the learning design is comprised of. It is intentionally aimed as a tool for use by practitioners and has been used extensively by teachers across different educational sectors. The learning design is represented as a sequence of activities visually illustrated as a flowchart. In contrast to the AUTC temporal sequence, LAMS sequences are usually represented from left to right. Examples of LAMS tools include typical teaching activities such as chat, question and answer, and forum. However, because it is designed to be runnable one of the weaknesses of LAMS is that it focuses the design around tools, and doesn't take account of all the other aspects involved in a learning activity. LAMS is discussed in more detail in Chapter 9.

A closely related body of work to learning design is research into the development and use of pedagogical patterns. This is discussed in more detail in Chapter 2. Derived from Alexander's work in architecture (Alexander, 1977; Alexander et al., 1977), pedagogical patterns is an approach to developing structured case studies of good practice (see for example Goodyear, 2005 for an outline of the field). Although of a slightly different nature to the other design languages described above, pedagogical patterns (Goodyear, 2005; Goodyear and Retalis, 2010) can also be viewed as a form of design language. Patterns consist of the following elements: pattern name, context for the pattern, description of the problem to be solved, solution, examples and links to related patterns.

The Open Learning Design methodology

The OU Learning Design Initiative

The OU Learning Design Initiative (OULDI)[22] emerged from previous work on the development of a learning design toolkit, DialogPlus (Conole and Fill, 2005; Fill, Conole and Bailey, 2008). Like the Phoebe and the London Pedagogical Planner (LPP) tools, DialogPlus was intended to act as a step-by-step guide to enable teachers to create learning designs.[23] The tool was based on an underlying taxonomy, which defined the

[21] See Learning Design – ldlite
[22] http://ouldi.open.ac.uk
[23] These pedagogical planner tools are discussed in Chapter 10

components of a learning activity (Conole, 2008), which was derived through a series of interviews with teachers about their design practices. However, evaluation of the actual use of such design planner tools indicated that they did not match actual design practice closely enough. Their relatively linear and prescriptive structure did not match the creative, iterative and messy nature of actual teacher design practice.

The OU Learning Design Initiative was initiated in 2007, supported through strategic funding from the OU and later through funding from the EU and JISC. The intention was to derive a more practice-focussed approach to learning design, identified from empirical evidence of actual practice. This included gathering 43 case studies of the ways in which the then new Learning Management System (LMS), Moodle,[24] was being used at the Open University UK (Wilson, 2007) and a series of interviews with teachers to articulate their actual teaching practice (Clark and Cross, 2010). The key focus of the teacher interviews was to better understand existing practice. The authors note in their introduction that:

> Even experienced academics who have participated in a range of course production tasks find it difficult to articulate how they go about developing a 'learning design' that will be transformed into effective learning materials (Clark and Cross, 2010).

The interviews focussed on five main questions: i) process: how do teachers go about designing a course?, ii) support: how do they generate ideas?, iii) representation: how do they represent their designs?, iv) barriers: what barriers do they encounter?, v) evaluation: how do they evaluate the effectiveness of the design?

A range of approaches to design was evident from the interviews, including gathering of resources, brainstorming, listing concepts and skills, creating week-by-week plans, etc. On the whole these were paper-based and primarily text-based. There was little evidence of use of alternative, more visual representations or visual software tools. Interviewees wanted help with understanding how to integrate ICT-based activities into courses. Face-to-face workshops and meetings were favoured over online support as they were felt to be the most effective way of thinking about, and absorbing new ideas and ways of working. Case studies interestingly were considered to be too demanding in time and effort, interviewees wanted just-in-time support to specific queries. The most effective form of support was considered to be sharing of experience with peers.

Although text-based representations predominated, a variety of representations were mentioned from simple textual representations or lists through to more complex and connected mind maps. The interviewees listed a variety of purposes for the representations, including: communicating personal vision, capturing or sharing ideas, comparing with others, viewing the course at different levels, and mapping content to learning outcomes.

Barriers included: concerns about a lack of experience of creating online activities and a lack of successful examples to draw on. An OU-specific issue was mapping the

[24] http://moodle.org/

innovative (and often idiosyncratic) ideas of course creators, with the needs of a production system delivering the OU's size and range of learning materials and services.

A range of mechanisms was cited in terms of evaluation approaches. These included feedback from students and tutors, comments from critical readers, peer course team critiques and comments from external examiners.

This empirical work provided a sound basis for the development of our approach. Our initial focus centered on the following questions:

- How can we capture and represent practice (and in particular innovative practice)?
- How can we provide 'scaffolds' or support for staff in creating learning activities that draws on good practice, making effective use of tools and pedagogies? (Conole, 2009).

We identified six reasons why adopting a learning design approach might be beneficial:
1. It can act as a means of eliciting designs from academics in a format that can be tested and reviewed with developers, i.e. a common vocabulary and understanding of learning activities.
2. It provides a means by which designs can be reused, as opposed to just sharing content.
3. It can guide individuals through the process of creating learning interventions.
4. It creates an audit trail of academic design decisions.
5. It can highlight policy implications for staff development, resource allocation, quality, etc.
6. It aids learners in complex activities by guiding them through the activity sequence.

These map closely with the benefits of adopting a Design-Based Research (DBR) approach outlined by Gibbons and Brewer (2005). They argue that the benefits include: improving the rate of progress (in the creation of designs), influencing the designer conceptions through making the design process explicit, helping to improve design processes, improvements in design and development tools, and bringing design and production closed together. Fundamentally, I would agree with their assertion that it opens up new ways of thinking about designs and designing, and in particular helps practitioners to shift from a focus on content to the activities the students will undertake.

We see 'learning design' as an all encompassing term to cover the process, representation, sharing and evaluation of designs from lower level activities right up to whole curriculum level designs. In previous work (Conole and Jones, 2010) we identify three levels of design: micro, meso and macro, drawing on Bielaczyc (2006) and Jones (2007). In our terms, the micro-level refers to learning activities (typically a few hours worth of activity), the meso-level to aggregations of activities or blocks of activities (weeks or months worth of activity) and the macro-level to whole curriculum designs. As part of their Curriculum Design programme,[25] the Joint Information Systems Committee (JISC) provide the following definition in terms of curriculum (JISC, nd):

[25] http://www.jiscinfonet.ac.uk/curriculum

> Curriculum design' is generally understood as a high-level process defining the learning to take place within a specific programme of study, leading to specific unit(s) of credit or qualification. The curriculum design process leads to the production of core programme/module documents such as a course/module description, validation documents, prospectus entry, and course handbook. This process involves consideration of resource allocation, marketing of the course, and learners' final outcomes and destinations, as well as general learning and teaching approaches and requirements. It could be said to answer the questions 'What needs to be learned?', 'What resources will this require?', and 'How will this be assessed?

We were interested in a number of research questions in particular. Can we develop a range of tools and support mechanisms to help teachers design learning activities more effectively? Can we agree a shared language/vocabulary for learning design, which is consistent and rigorous, but not too time consuming to use? How can we provide support and guidance on the creation of learning interventions? What is the right balance of providing detailed, real, case studies, which specify the detail of the design; compared with more abstract design representations that simply highlight the main features of the design? How can we develop a sustainable, community of reflective practitioners who share and discuss their learning and teaching ideas and designs?

Design-Based Research (DBR)

The next section describes the OULDI methodology, which is based on Design-Based Research (DBR). This section provides a brief overview of Design-Based Research. This section draws in particular on Barab (2006) and Kelly et al. (2008).

Design-Based Research (DBR) has emerged in recent years as an approach for studying learning in context through systematic design and study of instructional strategies and tools (Brown, 1992; Collins, 1992 cited in Design-Based Research Collective, 2003). Wang and Hannafin (2005, p. 5-6) define it as "a systematic, but flexible methodology aimed to improve educational practice through iterative analysis, design, development and implementation, based on collaboration between researchers and practitioners in real-world settings, and leading to contextually-sensitive design principles and theories".

Barab provides a useful overview of Design-Based Research (Barab, 2006, p. 155). He argues that the value of Design-Based Research (DBR) is that it offers a methodology for dealing with the complexity of real learning contexts by "iteratively changing the learning environment over time – collecting evidence of the effect of these variations and feeding it recursively into future designs" (citing Brown, 1992; Collins, 1992). He argues that cognition, "rather than being a disembodied process occurring in the confines of the mind, is a distributed process spread out across the knower, the environment, and even the meaning of the activity" (citing Salomon, 1993). Barab suggest that DBR can yield rich insights into the complex dynamics whereby theories become contextualised. He lists the following as mechanisms for making DBR effective:

1. Make the assumptions and theoretical bases that underlie the work explicit.
2. Collect multiple types of theoretically relevant data.
3. Conduct ongoing data analysis in relation to theory.

4. Invite multiple voices to critique theory and design.
5. Have multiple accountability structures.
6. Engage in dialectic among theory, design and extant literature.

He argues that DBR has the following characteristics: design, theory, and a problem in the context of a naturalistic setting, involving multiple iterations or progressive refinement (Figure 6). The figure shows the relationship between the underlying theory, design and problem being investigated within a naturalistic context and how this iterates and evolves over time. Kelly et al. (2008, p. 5) suggests that DBR foregrounds "the fluid, empathetic, dynamic, environment-responsive, future-orientated and solution-focused nature of design".

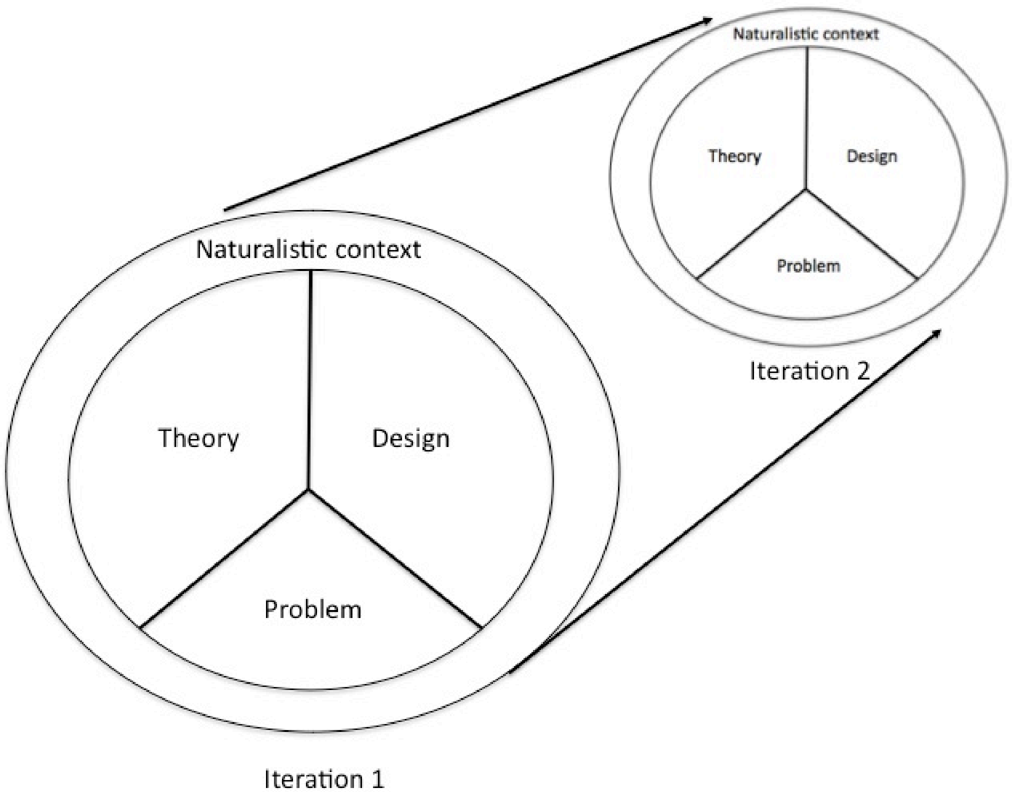

Figure 6: The interactive nature of Design-Based Research

The OULDI learning design methodology

We have adopted a Design-Based Research (DBR) approach; starting with a stated problem we were trying to address, a proposed solution and then an iterative cycle of developments and evaluation. Reigeluth and An (2009, p. 378-379) articulate a set of characteristics of DBR, which are listed below. The way in which the OULDI learning design methodology maps to these is described.

1. DBR is driven by theory and prior research. In our work, we are building on the substantive body of prior research on instructional design, the learning sciences, learning objects/Open Educational Resources, pedagogical patterns and more

recently learning design. As dicussed in Chapter 5, the approach we adopt is socio-cultural in nature, with a focus on the design and use of a range of Mediating Artefacts involved in the learning-teaching processes (see Conole, 2008 for a more detail account of this).

2. It is pragmatic. Our aim is to develop tools and resources which are useful to practitioners in actual practice, to address real educational challenges. Our intention is to be theory-driven, but pragmatic, recognising the complex, messy and often craft-based nature of teaching practice.
3. It is collaborative. We see working in close connection with end users as a vital part of our approach. Our initial interviews with teachers confirmed our view that teaching practice is complex and situated. Furthermore it is evident that design is not a linear process, it is creative, iterative and messy. Changing practice will only occur through close working with and understanding of practitioners' needs.
4. It is contextual. Our vision is to change actual practice, to achieve this it is important that the development activities occur in real, authentic contexts.
5. It is integrative. Wang and Hannifin (2005, p. 10) state that "DBR uses a variety of research methods that vary as new needs and issues emerge and the focus of the research evolves". We have adopted a mixed-method approach to evaluating our developments, matching the methods we use to the specific sub-research questions and the context that we are focusing on.
6. It is iterative. Our approach consists of an interactive cycle of identification of problems to be addressed, suggestion of proposed solutions, development, use, evaluation and refinement.
7. It is adaptive and flexible. Because our work is closely tied to actual practice, we need to ensure that the approach we are adopting is agile in nature, so that we can adapt based on evidence from changing practice.
8. It seeks generalisation. In addition to the practical, pragmatic nature of our work, we are also attempting to develop a coherent underlying learning design framework of concepts and approaches.

In essence, we are focusing on three aspects of design: i) the development of a range of conceptual tools to guide the design process and provide a means of representing (and hence sharing) designs, ii) the development of visual tools to render some of the conceptual tools and enable practitioners to manipulate their designs and share them digitally with others, and iii) the development of collaborative tools – both in terms of structures for face-to-face events, such as workshops and the use of digital tools, to foster communication and sharing.

For each aspect we have now developed a set of tools, resources and activities and over the last few years we have been trialling these in a range of settings, both with the OU and also externally with a number of partner institutions and through demonstrations and workshops at conferences. It would be impossible in the scope of this book to describe all the tools, resources and activities in detail; hence a selection will be described to give an overall view of the work to date. An evolving online learning design toolkit is being developed which includes our current set of tools, resources and activities.[26] In addition a

[26] http://cloudworks.ac.uk/cloudscape/view/1882

learning activity taxonomy has been developed (Conole, 2008) and more recently a Learning Design taxonomy which provides a map of the domain, the key concepts and where individual tools, resources and activities fit (Conole, 2010).

OULDI aims to bridge the gap between the potential and actual use of technologies outlined in the introduction, through the development of a set of tools, methods and approaches to learning design, which enables teachers to making better use of technologies that are pedagogically informed. Conole (2009) provides a reflection on the origins of OULDI and the benefits of adopting this approach. The aim is to provide a design-based approach to the creation and support of learning and teaching, and to encourage a shift away from the traditional implicit, belief-based approaches to design-based, explicit approaches. This will encourage sharing and reflection. The tools and resources are designed to help guide decision-making. The work is underpinned by an ongoing programme of empirical evidence, which aims to gain a better understanding of the design process and associated barriers and enablers, as well as an ongoing evaluation of the tools, methods and approaches we are developing and using and in particular to what extent they are effective.

There are three aspects to the OULDI: a set of visual design representations, a set of resource and activities, and mechanisms for fostering social interaction.
In terms of visual representations, we have created five views: a course view map (which provides an ‘at a glance’ overview of a course, a course dimensions view (which provides more details on the nature of the course - the degree to which it is collaborative, the level and forms of assessment, the amount of inclusion of user generated content or experience), a pedagogy profile view (which articulates the types of and amount of learner tasks), a learning outcomes map (which maps learning outcomes to activities and assessment) and a task swimlane view (which maps the tasks the learners undertake to the resources and tools they use). These are discussed in more detail in the next chapter.

In terms of resources and activities we have now created a rich set of these to support design practice. This includes use of the visual representations in a range of activities, as well as a number of other activities such as getting practitioners to think of the characteristics (affordances) of technologies in terms of how they might be used to support different pedagogical approaches.

Finally, to facilitate social interaction, we have created a range of workshops, as well as an online social networking site for learning and teaching, Cloudworks. The workshop include ‘Technology lite’ workshops where participants consider the characteristics of different technologies and how they might be used in their teaching, workshops on the use of the visualisation tools and a ‘Design Challenge’ workshop where participants work in teams to create a course in a day, assistance by a range of ‘expert stalls’ who provide advice on a range of topics (such as using web 2.0 tools, collaborative learning, assessment and the use of OER). The ‘Design Challenge’ workshop is similar in nature to the Carpe Diem workshop format (BDRA, 2011). Carpe Diem is described as a creative learning design process. At the end of the workshop, participants have a blueprint and a storyboard for the course, a set of peer-reviewed e-tivities, a model for further development and an action plan.

Cloudworks is a social networking site to facilitate the sharing and discussion of learning and teaching ideas and designs. It combines social and participatory functionality to enable multiple forms of communication, collaboration and cross-boundary interactions amongst different communities of users. The core object in the site is a Cloud, which can be anything to do with learning and teaching; such as a description of a learning intervention, a description of a tool or resource, a question, or a discussion point. Clouds can be grouped into Cloudscapes; a Cloud can belong to more than one Cloudscape. Clouds are a combination of social and participatory functionality. Firstly, they act like a multi-user blog; anyone can start a Cloud and others can sequential add content to it. Secondly, they have a space for discussion. Thirdly, users can enrich the Cloud by adding embedded content, tags, links and references. Finally they have additional Web 2.0 functionality, such as: an activity stream for the Cloud, the ability to tag, RSS feeds and Twitter-like follow and be followed options.

Conclusion

This chapter has focussed on the range of design languages that can be used to guide and represent learning designs. It has provided a rationale for the value of design languages and their uses. It has described a range of design languages as a means of illustrating their variety and the ways in which they can be used for different purposes. It has shown that some are available as computer tools, whilst others are simply conceptual in nature.

Design languages help make the design practice more explicit and hence shareable. They provide practitioners with scaffolded guidance on the design process and promote critical thinking and reflection. By externalising the design a teacher is better able to get an overview of the whole design and hence be able to see how the different elements of the design are connected and also to identify potential gaps or weaknesses in the design.

In the next chapter I will show how we have developed a range of design representations to foreground different aspects of the design process and will describe how these representations can be used. I will illustrate how these designs are being used by teachers and show how we have contextualised them in a range of different types of activities and workshops. In addition in Chapter 9 I will describe a range of design tools that have been developed, including a learning design tool that we have developed, CompendiumLD, that enables teachers to create and share designs. In Chapter 15, I will also describe the social networking tool, Cloudworks[27] that we have developed, which acts as a space for teachers to share and discuss learning and teaching ideas and also describe the types of user behaviour that are emerging in the site.

Chapter 8 Design representations

Introduction

This chapter will describe the range of ways in which learning interventions can be visualised and represented, along with a discussion of the benefits of each of these and how they can be used as part of both the design process and as a means of making the inherent design of a learning activity explicit. The chapter builds on a paper presented at the Networked Learning 2010 conference (Conole, 2010).

Types of representation

Learning designs can be 'represented' or 'codified' in various ways; each representation will articulate particular aspects of the learning that the designer anticipates will take place. Each design representation foregrounds different aspects of the inherent 'master' design, as discussed in Chapter 5. These forms of representation range from rich contextually located examples of good practice (case studies, guidelines, etc.) to more abstract forms of representation that distil out the 'essence' of good practice (such as models or pedagogical patterns). This section describes what is meant by 'design representation'. It gives an overview of the different types of representations; the formats they can be presented in, the level of granularity of design they portray and an indication of the particular ‘lens’ each representation provides on the inherent ‘master design’.

Conole and Mulholland (2007) outlined a number of common representations. These included essentially practice-focussed representations (e.g. case studies, lesson plans and patterns), conceptual representations (e.g. mind maps and metaphorical representations), more abstract representations (e.g. models and vocabulary) and technically orientated representations (e.g. UML[1] diagrams). They also argued that there are a number of uses of these different presentations. For example, enabling educational researchers to analyse and develop educational innovations, supporting teachers in planning learning interventions, facilitating software designers to instantiate lesson designs in software or supporting learners in understanding what they are doing and why. The type of representation is crucially dependent on its purpose.

This chapter builds on this work and describes different types of representations and how they can be used. Figure 1 provides a more generic description of the types of representation. Four main types of representations are identified: verbal, textual, visual, or data-based. A range of tools is now available to help visualise designs and in some cases, actually implement designs. Four examples are shown. LAMS[2] uses a link and node visualisation, but because LAMS sequences are ‘runnable’ the basic components of the system are tool-focussed (Dalziel, 2003; Dalziel, 2007). CompendiumLD[3] is also link and node based, but can be used across a broader range of granularity of designs (Conole et al., 2008). CompendiumLD maps can be exported in a variety of formats, but are not directly runnable. MOT+ is a graphical language and editor, which helps define activity sequences, actors and tools (Paquette, 2004; Paquette et al., 2008). Finally WebCollage visualises pedagogical patterns taking a metaphorically based approach to visualise designs around their description, such as ‘pyramid’ or ‘jigsaw’ (Hernández et al. 2005, 2006). These visualisation tools are discussed in more detail in the next chapter.

[1] Unified Modeling Language - see for example http://www.ibm.com/developerworks/rational/library/769.html

[2] http://lams.org

[3] http://compendiumld.open.ac.uk

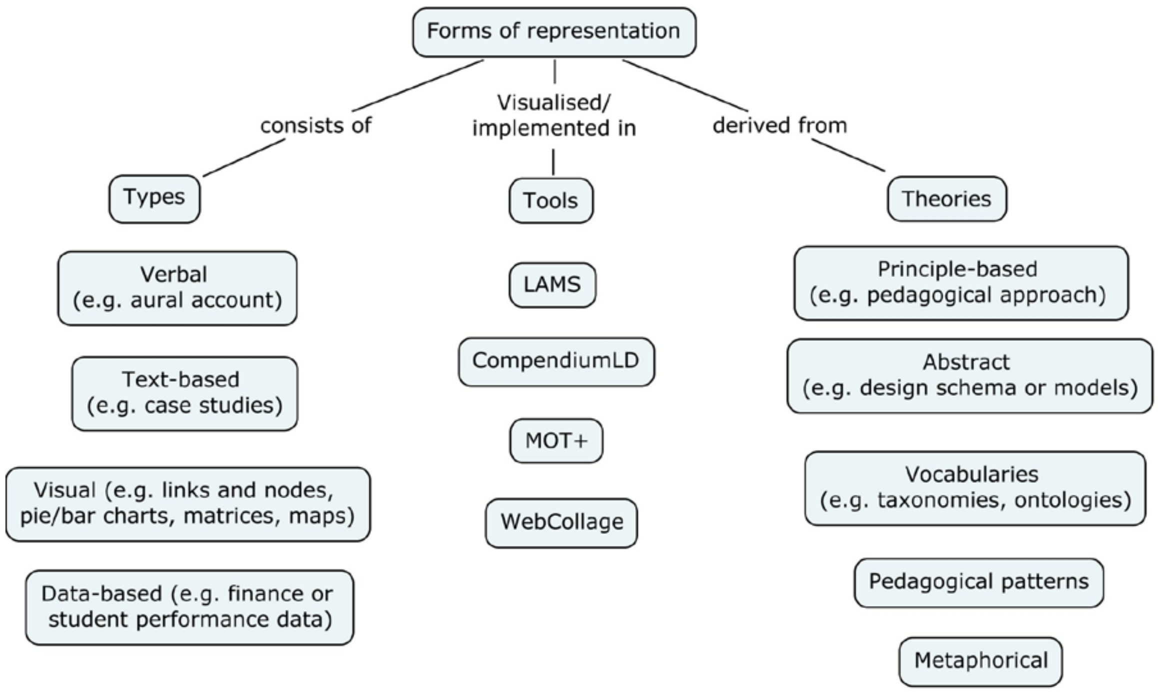

Figure 1: Forms of representation

Many representations are primarily practice-orientated in nature, however some have a particular theoretical basis. For example, designs which explicitly align with a particular pedagogical perspective such as constructivism or pedagogical patterns which have a prescribed format and are based on an underlying theoretical perspective based on the work of Alexander (see for example Alexander, 1977; Alexander et al., 1977; Goodyear, 2005; Goodyear and Retalis, 2010). Vocabularies (see for example Conole, 2008a) and abstract representations such as design schema and pedagogical models, such as Laurillard's conversational framework (Laurillard, 2002) are also examples of representations that are based on theoretical perspectives. Whilst clearly this is not a perfect classification it does give some indication of the breadth of types of representation that are possible.

Representations can have different formats, and can be used to describe different aspects of the design lifecycle and can provide different lenses on the inherent design, foregrounding specific aspects:

- Formats. These can include different types of text-based representations (e.g. case studies or narratives), visualisation representations (e.g. node-link types representations, design schema or metaphorical), numerically focussed (e.g. pie or bar charts based on underlying numerical data), representations based on other forms of media (e.g. audio or video) or representations can be a combination of the above.
- Levels. Designs can describe small-scale learning activities (which might describe a few hours worth of learning) or scale up to a description of a whole curriculum (across for example a three-year undergraduate degree course or a one-year masters course)
- Lenses. The focus might be on the nature of the tasks being undertaken and associated tool and resources, on the overarching pedagogical principles, in terms of

> mapping different components of the design together or exploration of data on the course performance and student evaluations (such as financial or student performance data).

Conole and Mulholland (2007) further classified representations into three levels.

> At a simplistic level this has an educational component (the pedagogical intention and aspiration) and a technological component (what technologies will be used, how and their associated affordances). A meditational layer, which describes the process or operational dimension, provides the link between these.

They go on to suggest that the educational view provides the underlying pedagogical model (such as the learning outcomes and pedagogical approach). The process-based/operational view focuses on enactment of the design. Examples include representations that are essentially stage-based (where the focus is on what is happening in a temporal sequence), or schema-based (which not only outlines the sequential set of tasks, but also the associated roles, resources, tools and outputs). The final technical view, they argue, provides the 'technical implementation blueprint' and the rule-based/runtime of the data flow.

Examples of different types of representation

This section describes a set of representations that we have developed as part of our learning design research. It will describe each representation, provide an illustrative example and suggest how each representation can be used. The representations presented here are not intended to be comprehensive, but to give a flavour of the variety of representations and an indication of their uses. They cover the spectrum of different types of format, level and lenses described earlier (Table 1). They include: textual summaries, content maps, a course view map, a pedagogy profile, a task swimlane view, a learning outcomes map, a course dimensions view and a principles/pedagogy matrix.

Table 1: Summary of the different types of representation

Representation	Format	Level	Lens
Textual summary	Text	Macro	Descriptive overview
Content map	Node-link	Meso, macro	Content hierarchy and structure
Course map	Boxes	Macro	Pedagogy overview
Task swimlane	Node-link	Micro	Tasks breakdown: roles, tasks, associated tools/resources
Pedagogy profile	Bar chart	Macro	Overview of learner tasks
Learning outcomes	Node-link	Macro	Mapping of outcomes to tasks and assessment
Course dimensions	Spider diagram	Macro	Details of the format of the course
Principles matrix	Matrix	Macro	A map of course principles to pedagogy overview

Textual

This is the most common way in which courses are represented. It can range from a brief textual overview plus descriptive keywords through to a more detailed breakdown of the curriculum covered and the associated learning, teaching and assessment strategy for the course. Such textual representations are common and form the basis of most course descriptions. Textual descriptions can also be used to indicate the pedagogical intent of the course or can be aligned to a particular theoretical basis, as is the case with pedagogical patterns, which follow a particular style and format. One of the drawbacks of textual descriptions of a course is that they tend to focus on the content and do not give enough of an indication of the nature of the learning activities that the students will do nor an overall picture of the learning experience.

Content map

Another common way of representing designs is in terms of content (Figure 2). Content can be organised in a number of ways, but a particularly helpful one is to organise it into a series of themes and sub-themes, although alternatives are possible that can be temporally based or metaphorically based for example. Buckingham Shum and Okada (2007; 2008) show how the Compendium software tool[4] can be used to represent content.

For example Figure 2[5] shows an example of a mapping of content related to the topic of literature analysis mapped in the Compendium tool. It shows not only the sub-topics but the relationships between them. Compendium can include a range of media, such as images, video and word documents.

[4] http://compendium.open.ac.uk/institute/
[5] http://compendium.open.ac.uk/institute/images/PhDDatabase.jpg

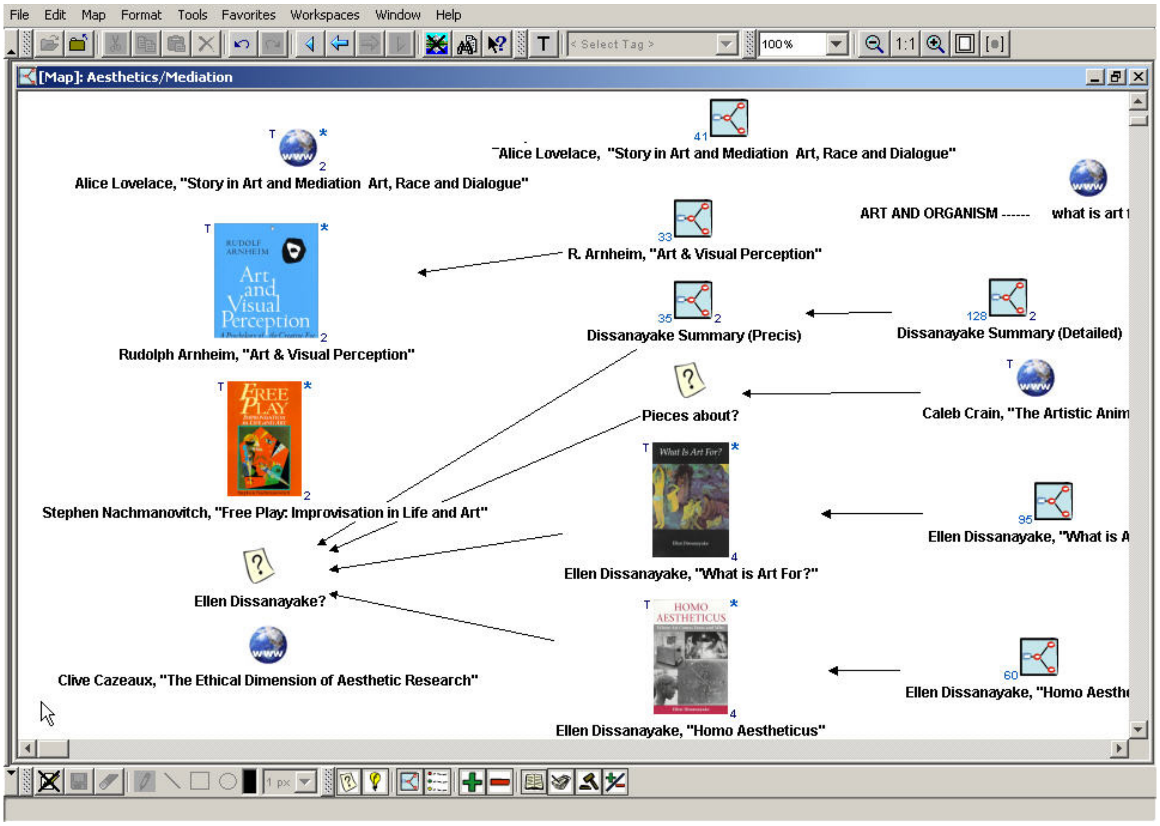

Figure 2: Compendium map of the concepts on a course on literature analysis

Similarly Figure 3[6] is an example of a mapping of a course on strategy. In this instance the map starts with a central topic/question, namely what is the meant by strategy, linked to a series of sub themes addressing the question.

[6] http://projects.kmi.open.ac.uk/osc/compendium/ou_cmap/

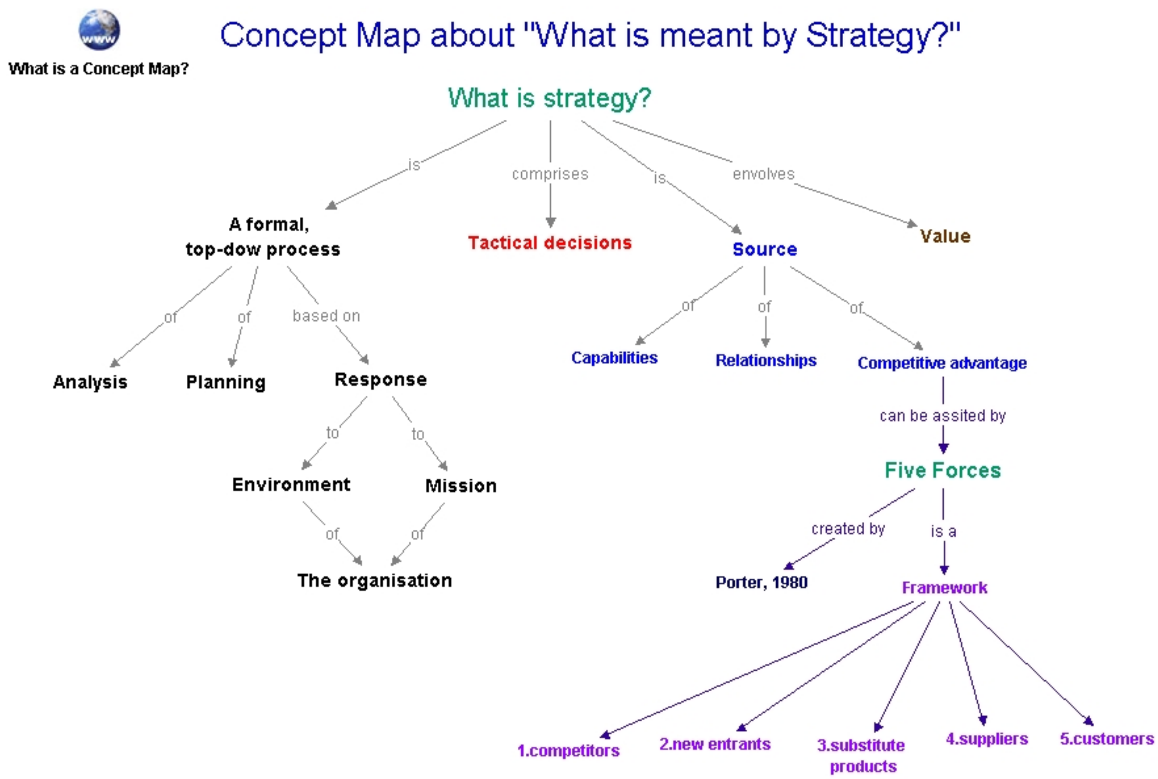

Figure 3: A concept map in Compendium on a course on strategy

The textual and content mapping representations are probably the most common ways in which teachers think about their designs. However, taking a more activity-focussed approach about using different tools/resources requires other representations.

Sherborne (2008) argues that:

Concept mapping could help curriculum developers and teachers at various stages of the [design] process. The ability of maps to focus on key ideas and their connections may help curriculum designers to survive better the translation into classroom experience and promote collaborative working methods.

The course map view

The course map view (Figure 4) provides an overview of a course at a glance and enables teachers to think about the design of the course from four meta aspects; namely:

- Guidance and support. This is essentially the learning pathway and includes details on the course structure and timetable. It can include aspects such as the course calendar, any study guides, information on tutorials and other forms of support.
- Content and activities. The includes information on the course materials and activities, ways in which the course builds on the learners' prior experiences and inclusion of any learner-generated content. Examples of materials might include: course texts and readings, DVDs and podcasts, whilst activities might include: laboratory or fieldwork, work-based placements or student project work.
- Communication and collaboration. This is essentially the dialogic element of the course. It is the social dimension of the course and describes the ways in which

learners are expected to interact with each other and their tutors. It might include the use of course forums, email or social networking tools.

- Reflection and demonstration. This is the assessment component of the course. It can include information on any diagnostic, formative and summative assessment. These might be achieved through multiple choice quizzes, assignment or formal examinations. In addition, there might be specific instruction at key points for the students to reflect on their learning and understanding to date.

In addition to these there are two boxes which provide a brief course summary and a list of key words.

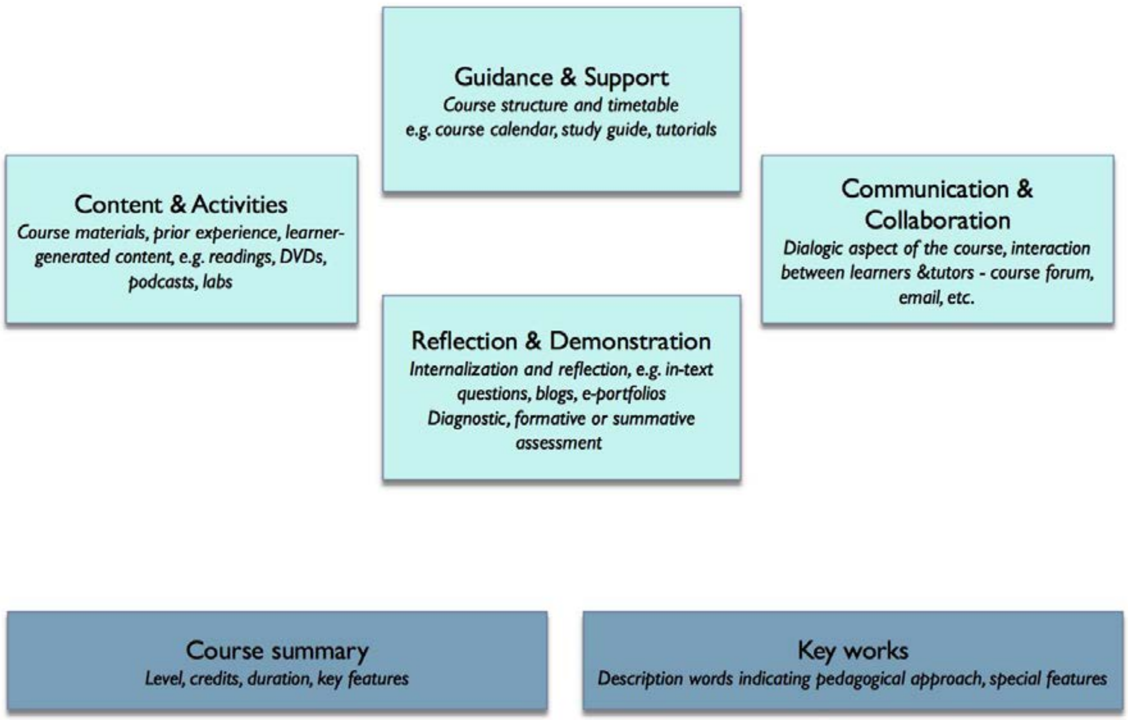

Figure 4: The course map view

The course map representation gives an 'at a glance' overview of the course. The representation is based on articulation of the gross-level aspects of what the learner is doing and how they are learning (information/experience, communication/interaction and thinking/reflection), the guidance/support they receive and the way in which they are expected to evidence/demonstrate their learning. A 3D-representation of the course map nicely illustrates the relationship between the different aspects of student learning and the overall guidance/support and the evidence/demonstration of their understanding (Figure 5).

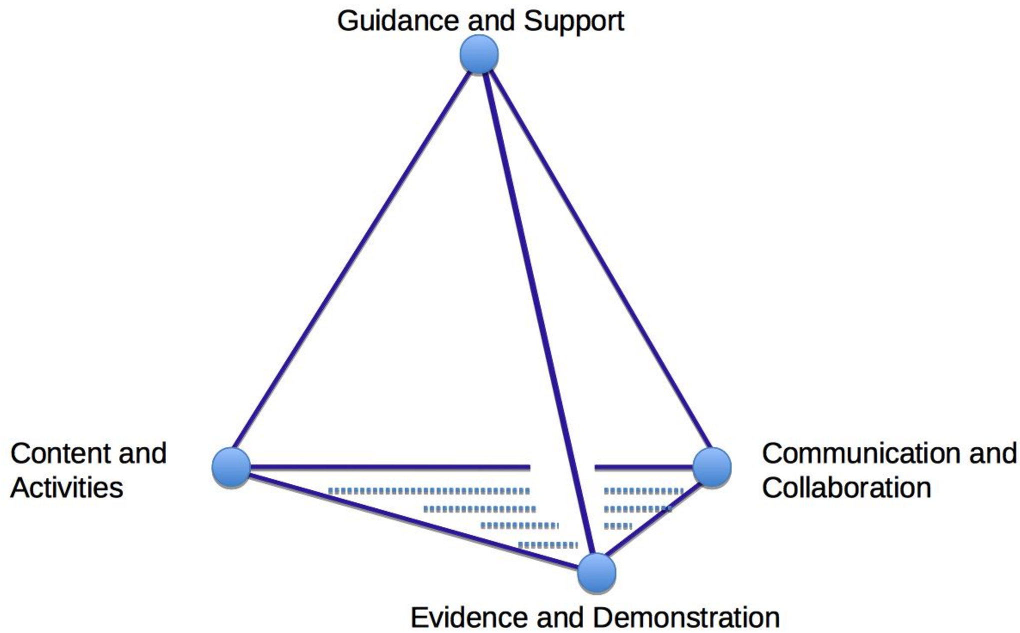

Figure 5: A 3-D representation of the course map view

The representation enables the designer to describe the course in terms of the types of learning activities the learner is undertaking, as well as the guidance and support provided and the nature of any assessment.

The course map is derived from an underlying theoretical perspective developed by Conole et al. (2004). Figure 6 shows that the different facets of learning can be mapped to three dimensions, i.e. the extent to which learning is achieved through: i) information or experience, ii) individually or in a social context, and iii) non-reflective or reflective. Guidance and support can be considered to sit within the centre of this representation. Contents and activities map to the information and experience dimension, communication and collaboration to the individual and social dimension, and reflection and demonstration to the non-reflective and reflective dimension. Interesting this 3D representation can also be used as a means of assessing how different tools are used in particular contexts and the extent to which these support the different facets of learning (See Conole, 2008a for more on this).

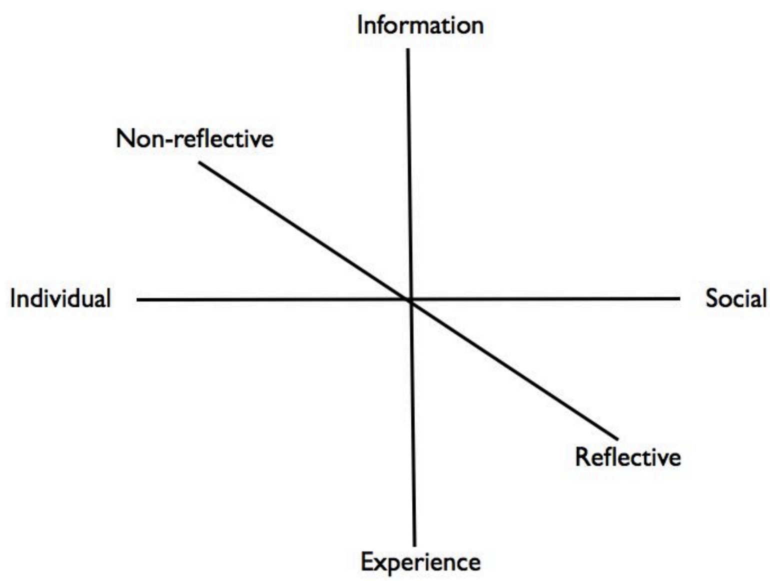

Figure 6: The three dimensions of the facets of learning

The pedagogy profile

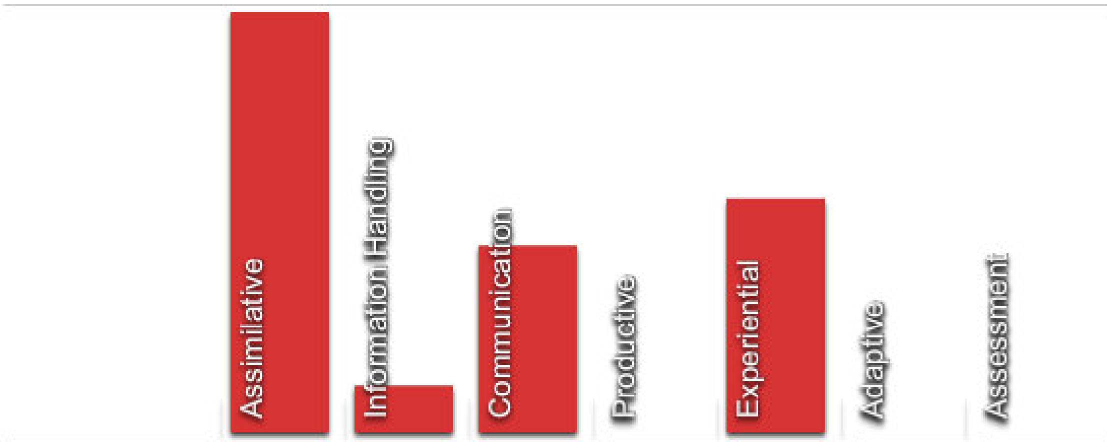
The pedagogy profile is a worked up version of the media advisor toolkit developed some years ago (Media Advisor, nd; Conole and Oliver, 1998), modernised against task types developed as part of a recently developed learning activity taxonomy (Conole, 2008a). In essence there are six types of tasks learners can do:

- Assimilative – reading, listening, viewing.
- Information handling – manipulating data or text.
- Communicative – discussing, critiquing, etc.
- Productive – producing an artefact such as an essay, architectural model, etc.
- Experiential – practising, mimicking, applying, etc.
- Adaptive – modelling or simulation.

In addition, learners undertake some form of assessment activities. The user indicates the amount of each type of task and the amount of assessment to create a pedagogy profile for a course – indicating the proportion of each type of tasks. An interactive pedagogy widget is now also available in the Cloudworks site.[7] Figure 7 shows an example of the use of the pedagogy profile to map four weeks of a course. In this example, the students spend 18 hours doing assimilative activities, four hours of information handling, eight hours of communication in the course forum and ten hours of experiential activities in the

[7] http://cloudworks.ac.uk/index.php/cloud/view/2459

form of a work-based placement. The advantage of this view is that it enables the designer to see the types and spread of learning tasks that the learners are engaged with. Often the assimilative and assessment activities are high, which may prompt the designer to rethink the nature of the tasks the learners are undertaking. In addition, this view is useful in that it can also be used by learners to profile the kinds of tasks they are engaged with. It would be interesting to compare the profile of a course from both the learner and teacher perspectives, to see how well they are aligned.



Item	Assim.	Info H.	Comm.	Prod.	Exper.	Adapt.	Assess.
Week 1	10	0	2	0	0	0	0
Week 2	4	0	2	0	0	0	0
Week 3	4	2	2	0	0	0	0
Week 4	0	0	2	0	10	0	0
TOTALS	18	2	8	0	10	0	0

Figure 7: The pedagogy profile

The task swimlane representation

The task swimlane representation describes the level of a learning activity typically a few hours in duration. It is derived from an underlying learning activity taxonomy (Conole, 2008b), which describes the components that need to be addressed when designing at this level (such as the tools and resources involved in the activity, the kinds of tasks the students will do, the roles of those involved in the learning intervention, etc.). This representation enables the designer to think about the relationships between the different components and any associated interdependencies.

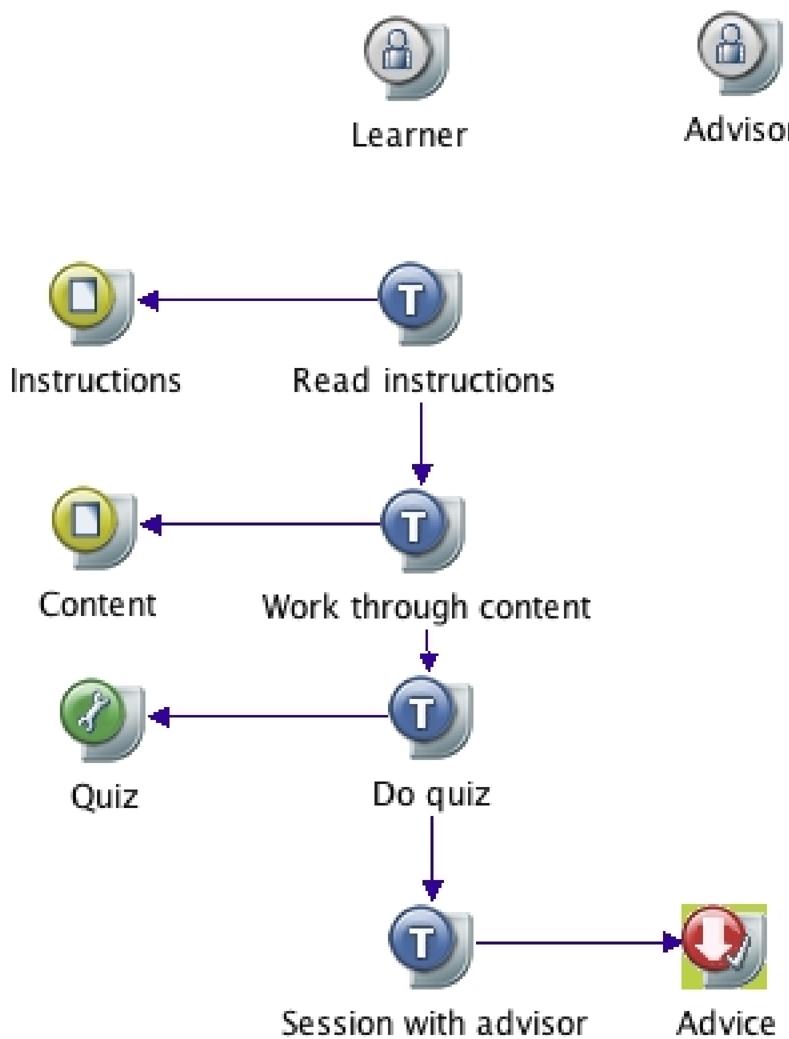


Figure 8: The task swimlane view

Figure 8 illustrates an example of the task swimlane view. It shows a simple learning activity, which consists of the learner reading some instructions, working through a set of content, doing a quiz to test their understanding and then having a feedback session with an advisor. The associated resources and tools for each task are linked to the relevant task node with arrows. This example was created using the CompendiumLD tool, which is discussed in Chapter 9

This is an example of what McKim (1980) categorises as a link-node diagram, where concepts/entities are represented as nodes and where the connections between the nodes have meaning. In our work so far nodes and links have been given equal weight, but it is also possible to use size or boldness as a means of conveying relative importance. The core learning design icon set in the tool are derived from an underlying learning activity taxonomy (Conole, 2008b). The tool also includes embedded help features and can be exported in a number of formats (see Conole et al. 2008 for more on CompendiumLD). Task swimlines can also be used to describe activities based on specific design types. For example the ‘Think-pair-share’ pedagogical pattern represented by Hernández et al. (2005) as a metaphorical visualisation, can also be represented as a task swimline.[8]

Learning outcomes map

In addition to mapping at the level of individual activities it is also important to be able to map at the meso- and macro-level in terms of mapping different components of the course; such as learning outcomes, content, activities and assessment. Standard mind mapping and concept mapping tools can be really helpful in laying out and making these kinds of connections explicit. A number of different configurations and layouts can be envisaged. The learning outcomes view enables the teacher to judge to what extent there is constructive alignment (Biggs, 1999) with the course, i.e. it looks at how the learning outcomes map to the student activities and to the assessment tasks. There are two aspects of constructive alignment. Firstly learners construct meaning from what they do to learn. Secondly, the teacher aligns the planned learning activities with the learning outcomes. So the learning intervention is designed so that the learning activities and assessment tasks are aligned with the intended learning outcomes.

The value of this view is that it enables the designer to check if all the intended learning outcomes are mapped to tasks and assessement activities. For example, Figure 9 shows a simple learning activity where one of the learning outcomes, concerned with collaboration, is not mapped to any tasks or assessment activities. The designer can then decide whether to include some activities to ensure this learning outcome is met or remove this as a learning outcome.

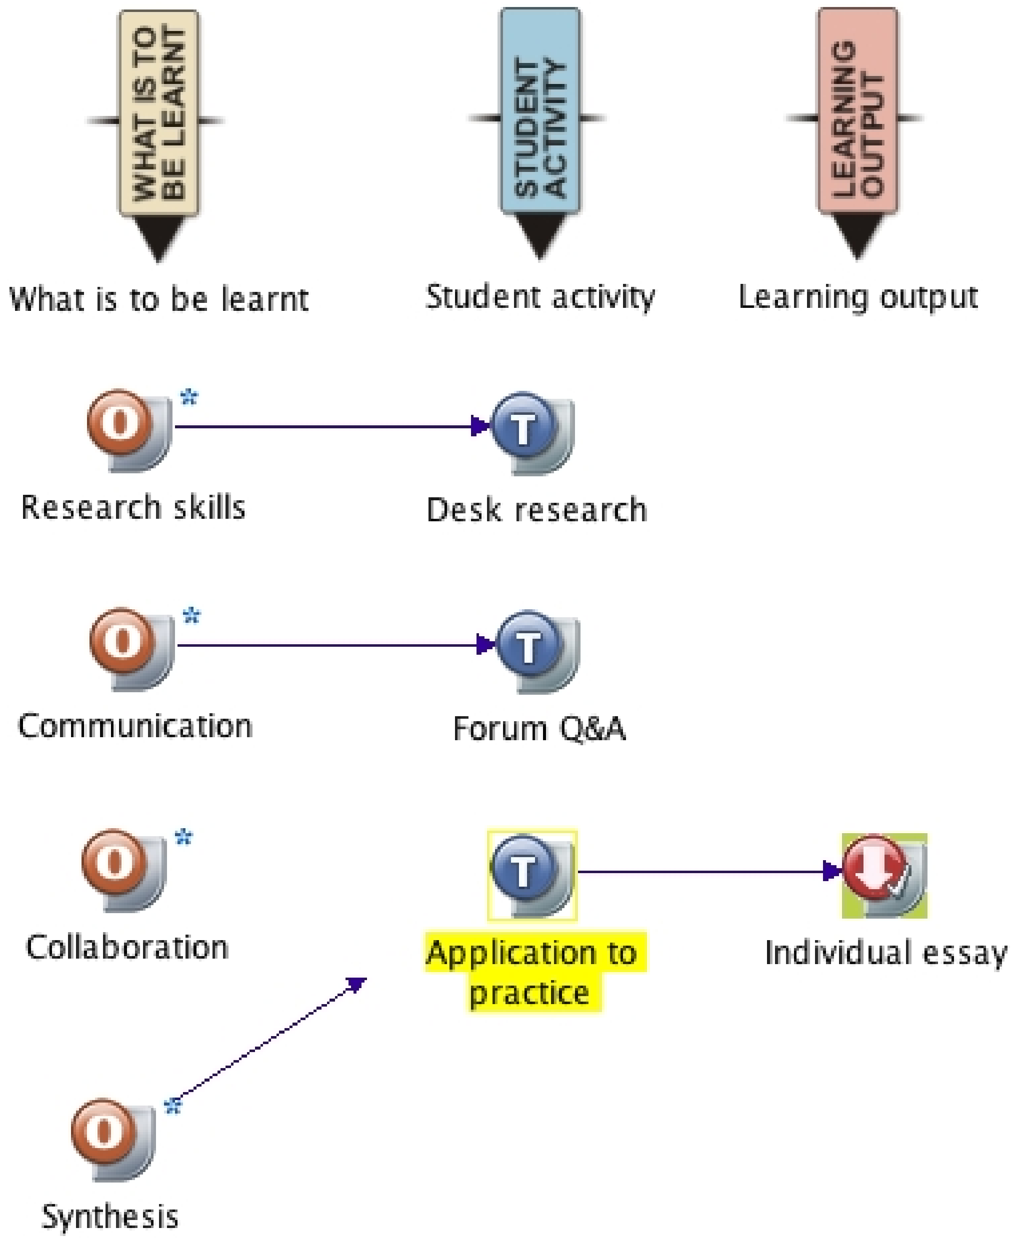

Figure 9: The learning outcomes map in CompendiumLD

The course dimensions view

The course dimensions view gives a more detailed indication of the nature of the course and how it is supported. It consists of four quadrants related to the four aspects of the course map view, namely: guidance and support, content and activities, communication and collaboration, and reflection and demonstration. In the example shown (Figure 10), there is a high degree of tutor guidance and peer support. In terms of content and activities the course is rich in terms of the amount of interactivity and the use of multimedia. However there is little in the way of communication and collaboration. The course has a high degree of both formative and summative assessment. The resultant spider diagrams provides a nice way of giving an illustrative view of what the course is like.

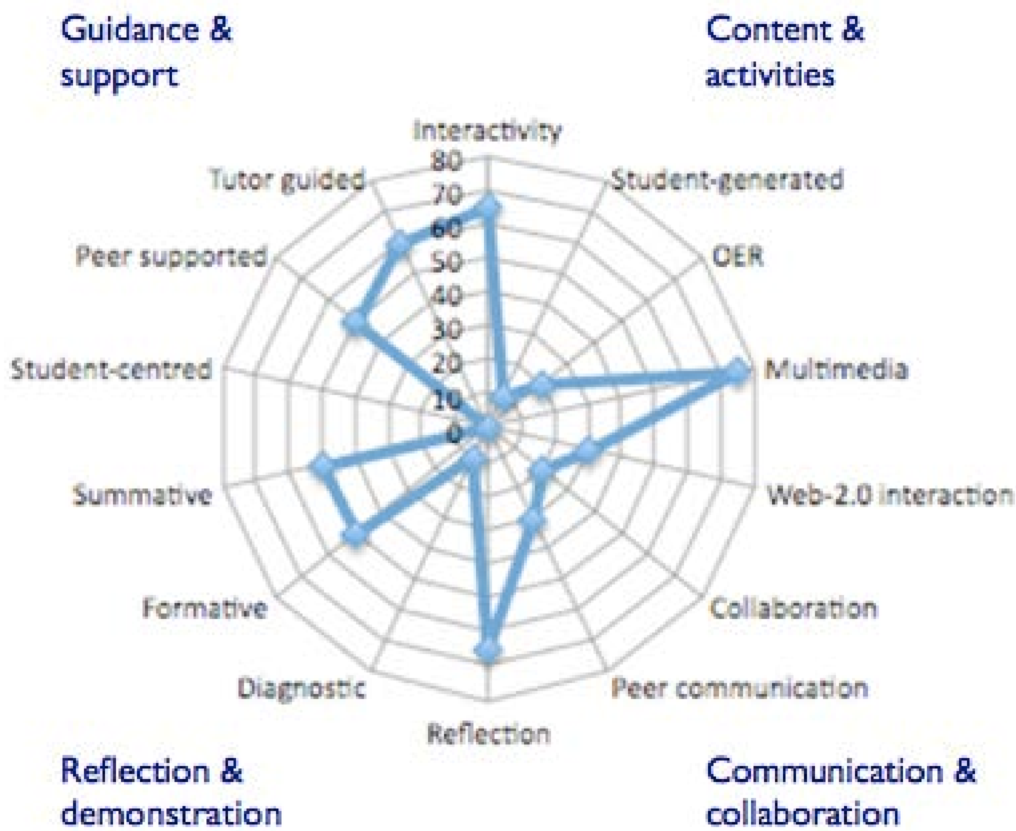

Figure 10: The course dimensions spider view

The principles/pedagogy matrix

This representation articulates the pedagogical approach being adopted by the course and the overarching principles (See Conole, 2008a for more details). It provides a matrix that maps the principles of the course against four macro-level aspects of pedagogy (Figure 11). Principles might be generated/articulated by the course team (for example getting the students to reflect on experience and show understanding or incorporating frequent interactive exercises and feedback across the course) or might be derived from theory or empirical evidence.

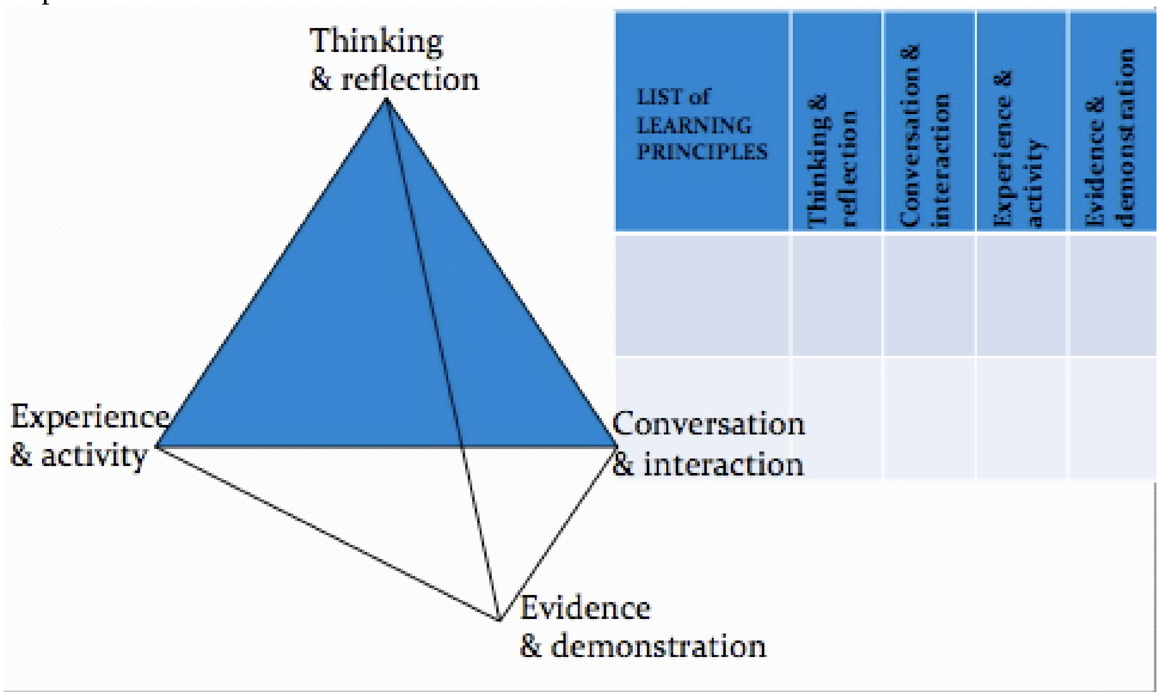

Figure 11: The principles/pedagogy matrix

Variants on the matrix are also possible. For example mapping principles to course activities, or mapping the principles to a different set of pedagogical characteristics (for example Bloom's educational taxonomy, the REAP principles (Nicols, 2009) or Laurillard's conversational framework (Laurillard, 2002).

Evaluation of the views

The representations presented here have been trialled in a number of venues and appear to provide robust and useful representations. These visualisations are enabling practitioners to be more creative in their design practice, thinking beyond subject content to a focus on what the learners will be doing. The task swimlane representation for example has been used extensively and is built into our visualisation tool CompendiumLD (Conole et al. 2008). The pedagogy planner and the course map representations were used at a Blended Design Challenge workshop, to help guide teams to design.[9] A 3D 'task-in-context to pedagogy' map has been produced, based on earlier work (see Conole et al., 2004 and Conole, 2008a).We have also being exploring data-derived representations such as views based on financial data for a course or student performance data.[10] We have also evaluated a series of workshops exploring the use of these design representations with pedagogical patterns work (Dimitriadis et al. 2009; Conole et al. 2010).

The emotional regulation learning intervention

The previous section described the general nature of the views, this section describes these applied to a particular learning intervention. The learning intervention was designed as part of the X-Delia project.[11] which is exploring the use of gaming and sensor technologies with traders and investors. The focus of the learning intervention is on developing emotional regulation in financial investors. The learning intervention consists of a series of interactive games. In terms of timescales the learning pathway is intended to extend over six months, different individuals will do different aspects and some may take forward into their work practice, therefore the following are intended as an indicative average amount of time on different aspects of the learning intervention; in reality different learners will spend a different amount of time working on this.

Figure 12 shows the course view map. The guidance and support consists of a self-directed learning pathway (up to six months). Content and activities are made up of a series of games, relevant didactic material and some real-world practice. There are no collaborative activities, but learners are able to communicate with peers in a discussion forum. There are no formal assessment activities, but the reflection and demonstration consists of diagnostic feedback and critical reflection.

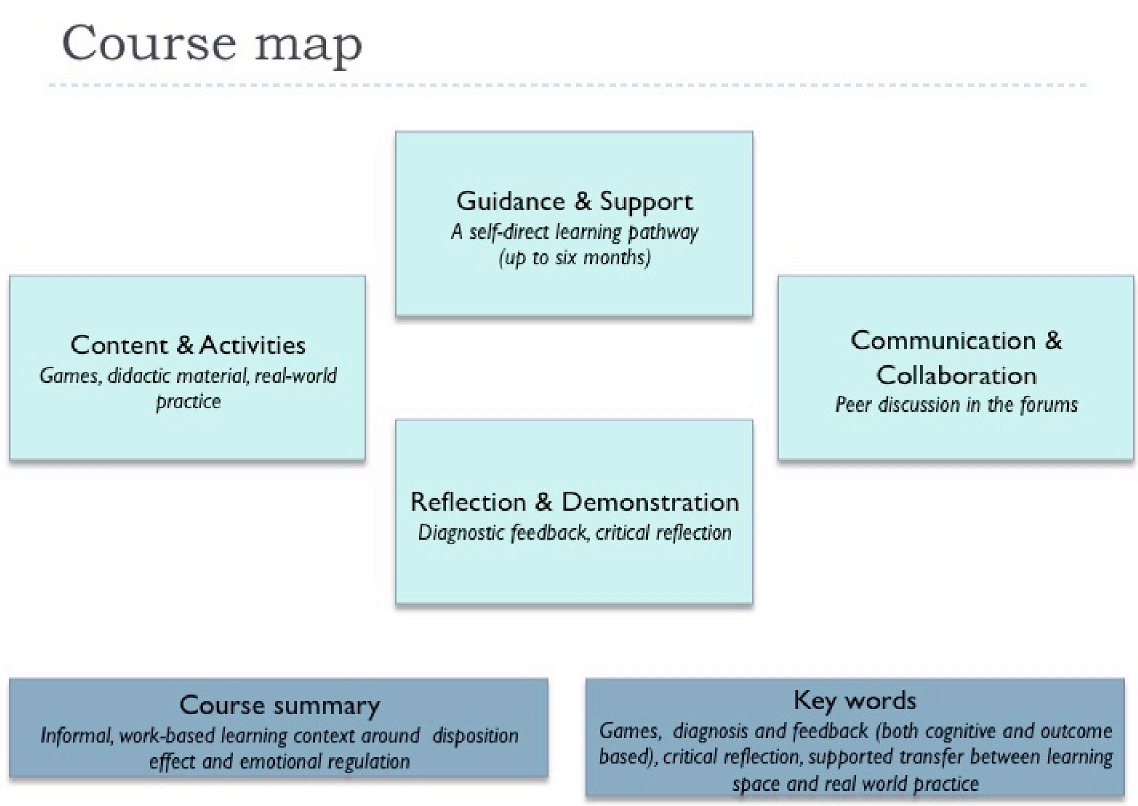

Figure 12: The X-Delia learning intervention course map

[11] http://www.xdelia.org/

Pedagogy profile

The pedagogy profile is shown in Figure 13, the learner activities break down as follows:

- Assimilative: didactic content (10 mins to 1 hr depending on choices made by the individuals).
- Information handing: the index game (for each iteration 30 mins – 1 hr) and aiming game (for each iteration 30 mins to 1 hr).
- Communication: peer discussion (zero to several times a week 1hr).
- Productive: none.
- Experiential: trading practice (1 hr per week to review the feedback).
- Adaptive: none.
- Assessment: diagnostic feedback (1 hr), critical reflection (10 mins at the end of every trading session).

	Assimilative	Info. Handling	Adaptive	Communicative	Productive	Experimental	Assessment
Percentage	4%	9%	18%	7%	18%	36%	7%
Total hours	2	5	10	4	10	20	4
Diagnostic activity	2						4
Disposition effect games		1	5			5	
Emotion regulation games			5			5	
Deliberative trading practice						10	
Structured diary and template work					4		
Critical reflection		4			6		
Asynchonous peer disc				4			

Figure 13: The X-Delia learning intervention pedagogy profile

Course dimensions

The course dimensions view for the intervention is shown in Figure 14. It indicates that the learning intervention is very activity-based, with little in the way of tutor support. Reflection and demonstration of learning is mainly through self-reflection.

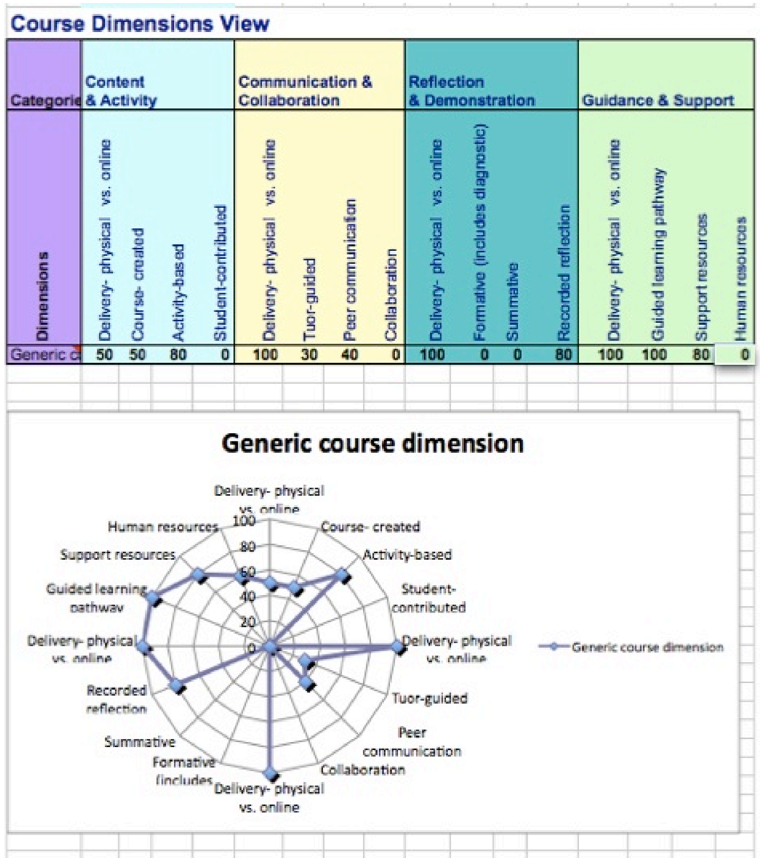

Figure 14: The X-Delia learning intervention course dimensions view

Learning outcomes

There are four learning outcomes associated with the intervention:

- Understand the disposition effect[12] and emotional regulation.
- Improved awareness of own profile in relation to the disposition effect and emotional regulation.
- Develop skills in relation to the disposition effect and emotional regulation in a learning environment.
- Support a transfer of skills into practice.

Figure 15 shows how these map to the various learning activities, all four are covered and indeed in all instances the learning outcomes map to two or more of the tasks.

[12] http://en.wikipedia.org/wiki/Disposition_effect

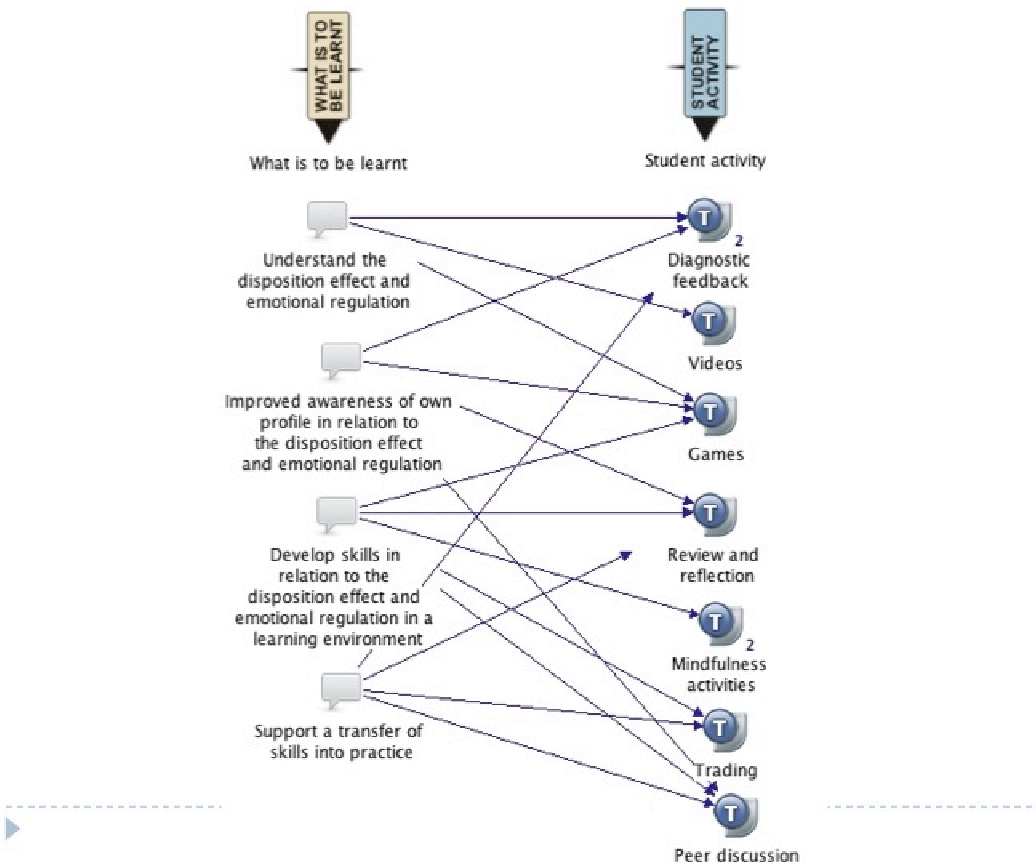

Figure 15: The X-Delia learning intervention learning outcomes map

Task swimlane

The following learning activities make up the learning intervention (Figure 16):

- Diagnostic feedback through an e-assessment tool, a questionnaire and calculations based on their existing trading history if they have one, and the two-index game.
- Some propositional knowledge through a series of videos, whereby different video segments are delivered based on the learners' response to the survey and calculations. Feedback becomes a vehicle for individualised didactic delivery of content.
- Engaging with two games iteratively: i) the two index game (disposition effect) in which the learner gets feedback each time on the extent to which they are displaying a dispositional effect and ii) access to a play environment where they can manage their emotional arousal in the aiming game. Each game has a number of levels of difficulty.
- Learning interventions about developing mindfulness, which is delivered online, this includes a tool on paced breathing meditation.
- Using sensors to review their emotional status in a trading context in a day trading centre (optional).
- Access to a peer discussion space so that the learners can come together in peer learning groups in discussion forums.

- Writing down and reviewing real world trading practices, and engaging in critical reflection. This includes recording and reviewing emotional state (for example rating themselves on the extent to which they have experience particular emotional states). Also make notes on what causes the emotions and what impact they think that has had on how they behave.

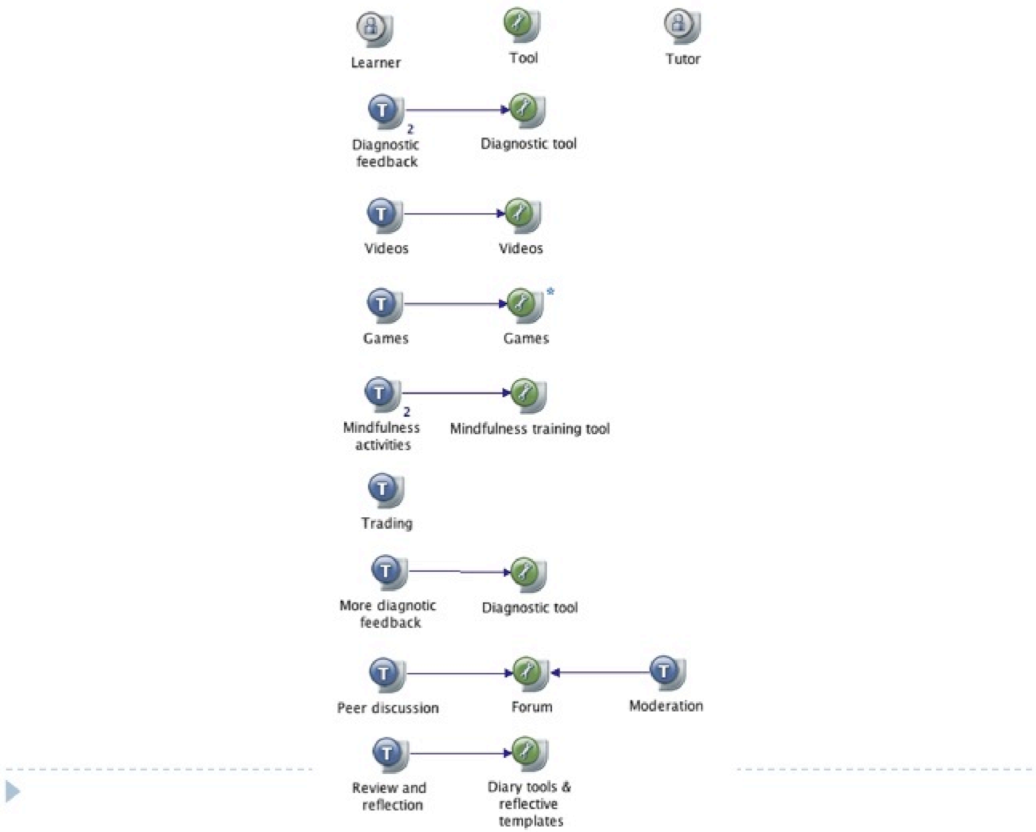

Figure 16: The X-Delia learning intervention task swimlane view

Conclusion

Representing design in a range of formats, beyond simple text, can help practitioners to think more creatively about their designs and can lead to new insights and understandings about the design process. There are parallels with Vygotsky's (1962; 1978) notions of language as a Mediating Artefact, "thought is not merely expressed in [drawings], it comes into existence through them" (quoted in Stubbs and Gibbons, 2008, pg.37). This chapter has attempted to categorise and outline a number of representations and their purposes. The selection chosen attempts to cover the full spectrum of designs: from learning activities to whole curriculum designs. But as Stubbs and Gibbons (2008, pg.46) point out "As important as drawing may be to the design process, it rarely stands alone. Design drawings are nearly always accompanied by narrative, which supplements and adds meaning". They quote Bruner (2003):

We organise our experiences and our memory of human happenings mainly in the form of narrative – stories, excuses, myths, reasons for doing and not doing and so on.' whereas visual representations, on the other hand, 'can render phenomena, relationships and ideas visible, allowing patterns to emerge from apparent disorder to become detectable and available to our senses and intellect.'

This chapter has described some of the work we have been doing in terms of describing designs. It has contextualised this in broader work in the field. It is evident that there is currently a lot of interest in this area and that we are moving towards a clearer understanding of different types of representations and how they can be used.
